

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. A Course of Lectures

ON

THE EYE: ITS DISEASES, AND THEIR REMEDIES.

*Being an Abstract of a Course of Lectures delivered in the
Royal College of Surgeons in Ireland*

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
Professor of Ophthalmic and Aural Surgery in the College;
Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 525.)

MUCO-PURULENT ophthalmia is very frequently a complication or a sequela of the exanthematous fevers—small-pox, scarlatina, and measles. The

inflammation is simply an extension of the general skin eruption to the conjunctiva, and it partakes of the character of the eruption peculiar to the original disease, presenting the characteristics in scarlatina of simple catarrhal ophthalmia, in measles of a much more decided muco-purulent inflammation, and in small-pox of a severe pustular ophthalmia, of either confluent character, or with distinct pustules. The occurrence of these eye symptoms in connection with the exanthemata marks the fact that the conjunctiva is a modified skin structure, and illustrates the propriety of treating its diseases on the same plan as other diseases of mucous membranes.

It is unnecessary for me to dwell upon the treatment of the simple catarrhal or muco-purulent conjunctivitis, which accompanies measles and scarlatina, for it differs in no respect from the treatment of these diseases where they occur idiopathically, except that leeching and blistering are not applicable. In the pustular form special to small-pox, special precautions are necessary, for there is much risk of the cornea becoming involved in ulceration and presenting cicatrices after the patient has recovered. It has been denied by some authorities that pustules are ever developed upon the ocular conjunctiva

or cornea, but I have myself seen undoubted pustular conjunctivitis accompanying small-pox which could not be confounded with any other disease, unless, indeed, an aggravated attack of phlyctenular ophthalmia concurrent with the small-pox. Bad forms of variola are now happily rare, in consequence of the beneficial influence of vaccination, but twenty or thirty years ago, when a large proportion of the Irish population was unvaccinated, and when small-pox inoculation was rife, the virulent form of the disease was common, and the workhouses were full of the blind victims of the eye disease attendant on it.

In the treatment of this form of pustular ophthalmia, the exposure of the eye to air and light, which is so beneficial in phlyctenular disease, is not suitable. On the contrary, the eye should be covered with a compress bandage, with the view of aborting the pustules and preventing avoidable irritation from the motion of the lids; but the pad should be removed several times, the eye cleaned of discharges, and a very dilute ung. hyd. oxid. flav., not stronger than gr. 3 to the ounce, applied. If the eye be kept continuously bandaged there is a risk of the formation of permanent adhesions or *symblephara* between the conjunctiva of the eye and lid, which, if at all extensive, are fatal to the future usefulness of the eye. As the disease passes off and the pustules are nearly healed, the pad must be thrown off and the usual treatment of the third stage of muco-purulent ophthalmia adopted. These pustules, though I have not seen them develop on the cornea itself, frequently occur on its conjunctival margin and—being deep and extensive—involve the cornea very seriously in purulent infiltration, abscess, ulceration, and even perforation, these being the chief dangers of the variolous form of disease, and resulting in disfiguring opacities, prolapse of the iris, and staphyloma. The occurrence of pustules in this situation must be watched, and if they appear should be made to restrict their dimensions by hot stuping and by opening the pustule the moment the pus shows itself. But, notwithstanding all these precautions, there will frequently remain partial loss of corneal structure and opacity.

A "secondary variolous ophthalmia" sometimes occurs

after the eruptive stage of the disease has passed away, but this is not characterised by the development of pustules. It is a simple muco-purulent ophthalmia, apparently related to the desquamative condition of the skin, and as it does not usually present serious corneal complication a special line of treatment is not needed.

Diphtheritic Ophthalmia. A form of acute conjunctivitis characterised by the deposition of a croupal membrane in patches, must be mentioned, but its symptoms and

treatment need not be dwelt upon by me, inasmuch as the disease is almost unknown in Great Britain. I have never myself seen a case in this country, but it is not uncommon in Germany, where it assumes an epidemic character. It differs essentially from the ordinary type of acute conjunctivitis by the absence of the muco-purulent discharge. The lids are greatly swollen, but instead of being soft and oedematous, they are hard, glistening, and very painful to touch. The discharge is sanious, sero-sanguineous, and scanty, and the conjunctiva shows a reddish-grey colour instead of the purple-red villous surface usual in ordinary ophthalmia. These symptoms merge in the stage of resolution of the disease into the symptoms of ordinary conjunctivitis, the lids being soft, the ocular conjunctiva vascular, and the discharge muco-purulent. The disease is more common in subjects of a poor, strumoid constitution, or where there is a taint of hereditary syphilis, and is extremely dangerous, the tendency to sloughing and ulceration of the cornea being greatly enhanced by the obstruction of blood supply arising from the hardness and tension of the conjunctiva. Incisions of the conjunctiva to relieve this tension are comparatively ineffectual, as they do not give exit to the infiltrated matter as they do in cases of ordinary chemosis. The treatment of these cases consists in as rapidly as possible improving the hygienic condition of the patient, and, by the aid of poultices and hot stupes, seeking to restore the circulation which is obstructed by the fibrinous infiltration. The rapid administration of mercury, which is contra-indicated in ordinary ophthalmia, is here necessary, for the purpose of causing the absorption of the infiltrated substance, but the treatment is at best only partially successful, and the progress of the disease is commonly so rapid that the cornea is lost before it is possible to bring the patient under the influence of the mercury.

Phlyctenular Ophthalmia. The forms of ophthalmia which I have described involve the entire conjunctiva, and are true inflammations running a definite course.

Phlyctenular conjunctivitis, or herpes conjunctivalis, is, on the contrary, an affection purely local, and not involving the conjunctiva generally. It is characterised by the recurrent development of minute phlyctens or herpetic pimples, the usual situation of which is upon the margin of the cornea. The attack commences with itching and smarting, which causes the patient to rub the eye constantly; this is attended with a very abundant discharge of tears, and with constantly-increasing photophobia, or intolerance of light, and the attack comes to an end by the phlycten breaking into a minute ulcer, and, after a day or two, healing up, only to be succeeded, *ad infinitum*, by other phlyctens which run a similar course.

The disease is one of low vitality and is almost special to children between the ages of 7 and 17, being never seen in the infant, and very rarely in middle life or old age. It is so commonly associated with the strumoid taint, with enlarged sub-lingual glands and herpetic eruptions about the nose, the angles of the mouth, and the lobes of the ears that it has been, heretofore, called strumous ophthalmia, and with great propriety, treated with iodides and cod-liver oil. When the disease is commencing a small granule of herpetic effusion is seen at the corneal margin to which a bundle of conjunctival vessels is seen to converge, and as the affection progresses the phlycten enlarges and the conjunctival vascularity extends more or less throughout the conjunctiva, but not

to the extent of inducing the muco-purulent discharge of a true conjunctivitis. As the phlycten forms the exposure of the eye to light becomes painful, and when

Fig. 6. Phlyctenular Conjunctivitis.

it has become an ulcer and has involved the corneal margin this photophobia becomes intense and is the chief feature of the disease. The attitude and appearance of the patient are quite sufficient diagnostic signs, and it is difficult to mistake any other disease for this phlyctenular ulceration, photophobia not being developed to the same extent in any other affection. The prognosis of the disease is good, and, as a rule, there is no danger to sight, nor any risk of disfigurement unless the cornea comes to be seriously engaged in the ulceration. In such cases a nebula will remain as the mark of each phlycten, and the accumulation of these slight opacities will eventually injure the sight, or the corneal ulcer may go deeper and perforate the anterior chamber in which case we may have a prolapse of iris and permanent damage to the eye.

The treatment of phlyctenular ophthalmia is above all things hygienic and tonic, and it ought to be well understood that in this disease the depressant and antiphlogistic line is altogether unsuitable and injurious. The only difficulty of the treatment lies in the photophobia which induces—almost coerces—the patient to seek the shelter of a warm and dark room, and to soothe the eye with hot stupes, poultices, and bandages. Such a course contributes materially to the disease, because the confinement to a close atmosphere, and the prevention of personal exercise are certain to add to the low condition of vitality which is the origin of the disease. For the same reason leeching, continued purgation and low diet are altogether injudicious, except when the herpetic ulceration has engaged the cornea and other deeper structures. In such a case, a couple of leeches and a hot sedative stupe may be necessary, and, in any case, a gentle antacid and stomachic aperient will be beneficial at the outset of the disease, but further than this depletion should not go, and to any extent to which this treatment may be carried must be made up afterwards by tonic treatment.

The course which I have found most beneficial generally is as follows:—If the case is seen when the phlycten is forming, give at once the mercury and chalk powder, which I have already suggested for incipient conjunctivitis, and accompany it with a quinine mixture. I find the compound tincture of bark with three grain doses of iodide of potassium very efficacious where it is desired to bring the system rapidly under tonic influence. At the same time, the dietary should be looked to, and made abundant and nutritious. For young subjects I prefer farinaceous food, such as porridge and corn flour and rice, abundance of milk—if digested—and also eggs, chicken, fish, and a little underdone fresh meat are useful, but I would not force an abundant meat dietary.

The idea which the average mother has of a generous diet for a child is a cup of beef-tea with plenty of arrowroot or jelly, none of which nutriments will to any extent supply the place of milk, eggs, and well cooked oatmeal. Beef-tea is entirely unobjectionable, and as a help to other means of alimentation it is useful; and the same may be said in a less degree of arrowroot, sago, tapioca, and other starch foods and of jelly, which is usually nothing better than a pinch of gelatine dissolved in water and nicely flavoured.

If the photophobia becomes intense, and after-ulceration

of the phlycten has taken place, it may be desirable, for the sake of keeping the eye at rest and preventing friction, to apply a wet compress and bandage over the eye, but the sooner it can be dispensed with the better, because the photophobia is greatly increased by keeping the retina in darkness, and therefore such light as can be borne should be admitted. For this reason the patient should not remain in bed beyond usual hours, and should on no account be permitted to lie on the face, or keep the eyes covered with band or handkerchief; or, if a child, to lie face downwards on the nurse's shoulder when carried out of doors. When at all possible the child should sleep in a cot by itself with not too much covering, and no curtains. The ventilation of the room should be abundant, and the light moderate, and the patient's eyes will be sufficiently guarded by sitting in a distant corner with the back to the light. In fact, fresh air, exercise, and moderate light act as a charm in these cases, and should be had every day, and all day if possible. There is no special risk to the eyes from catching cold, and therefore, even in unfavourable weather, the patient should go out—walking exercise being preferable to driving in carriages or cabs. To obviate the disposition to lie face down on the nurse's shoulder, or to keep the hand up to the eyes, the child—if able to walk—should be led by a person holding each hand, and allowed to rest by sitting down from time to time. The first day of this treatment will be painful, but each day of perseverance afterwards will show a decided improvement until the patient is perfectly well.

This photophobia may be, in some degree, alleviated by special local treatment, of which the installation of a three grain neutral solution of sulphate of atropia (a) is most favoured.

I cannot say that I have much confidence in atropia as a sedative, but I know that it is liable to increase the photophobia by admitting a flood of light to the retina through the dilated pupil. I shall, however, speak of the use of it and of eserine further on. I prefer the old-fashioned vinum opii, which I have found to be powerfully sedative in all irritable ulcers, sufficiently astringent and stimulant and not too irritating. When the ulcer is open, and is slow to heal the application of calomel upon its surface is very useful, but it must be done properly or not at all, or if a quantity of it is left within the lid it causes much irritation. It is also by no means easy to apply it effectually, as the photophobia makes it almost impossible to expose the cornea. The only way to manage it effectually in the child, is to put the head between your knees—the hands and legs being controlled by an assistant—and to raise the lid with a speculum. The point of a dry camel's hair brush being dipped in the dry calomel powder, the brush should be held horizontally between finger and thumb, and the brush filiped sharply with the third finger, so as to jerk the powder upon the ulcer surface.

If, after the ulcerations have healed up, a chronic conjunctivitis remains, it may be cured by brushing the lid with a ten grain solution of silver nitrate and by Pagentecker's ointment, for which I have already given a formula. The constitutional treatment is all important, and the hygienic treatment, to which I have already referred, should be supplemented with a long continued course of iodide of iron. A teaspoonful of equal parts of syrup. ferri iodide and syrupus cinchonæ thrice daily is suitable, but, in dispensary practice the less expensive simple syrup may be substituted for the syrup of bark, with sacrificing much of the efficiency of the mixture. This should be continued for at least six weeks, and the patient should be reminded that occasional relapses are to be expected before the disease is finally got rid of.

- (a) R Atropiæ sulphatis, 3 gr.;
Acid. sulph. dil., 3 gr.;
Aq. rosar. ad ℥j;
Ft. collyr.

The dilute sulphuric acid is added to ensure solution of the atropia salt, and the rose water being made of distilled water is suitable. The liq. atropiæ of the Pharmacopœia contains spirit, and is painful and irritating to use.

CATHETER FEVER. (a)

By SIR ANDREW CLARK, BART., M.D., LL.D.,
Physician to the London Hospital, &c.

SOMEWHERE about the year 1850, one of the medical officers of Haslar Hospital (who, I dare say, will be kept in remembrance by my former messmate, Sir Joseph Fayrer), between fifty and sixty years of age, of nervous constitution, but apparently in robust health, requested me to examine his urine. Accordingly, I submitted it to as careful an examination as I was then competent to make, and all that I could find out against it was, that it was too great in quantity, too low in density, and too pale in colour. He then informed me that he had trouble with his bladder, that he meant to consult Sir Benjamin Brodie, and that he wished me to accompany him for that purpose to London. Sir Benjamin examined his patient, drew off a large quantity of urine from the bladder, told him he was suffering from simple enlargement of the prostate, prescribed the regular use of the catheter, and with a few general cautions against a careless diet and exposure to cold he quickly but kindly dismissed us both. We returned to Haslar. In about a week, the patient was free from local discomfort, and without complaint of his general health, but then he began to feel and to look ill. He complained of *malaise* and weakness, and of general pains. He lost his appetite; was tormented by thirst; had nausea; became feverish; took to his bed; got daily worse; and, notwithstanding the efforts of his colleagues, who could not agree as to the nature of his malady, he died in about three weeks from the beginning of his illness. No post-mortem examination was allowed. The case here so imperfectly narrated made upon my mind an impression which has never been effaced; but, until about the year 1865, I saw no other case exactly resembling it.

In that year, I was summoned by Mr. Peter Marshall to visit a gentleman suffering from fever. Certainly he was in what is called vaguely amongst our elder brethren, a typhoid state. He was between fifty and sixty years of age. He was lying on his back in bed, apparently in a state of great prostration. The face was faintly yellowish and mottled, the lips dry, the pupils dilated, and the breath fœtid. The tongue was small, brownish red, dry, tremulous; there was complete anorexia. The bowels had been imperfectly relieved. The urine, habitually removed by the catheter, was low in density, acid, and deposited on standing, a little muco-pus, and contained a small quantity of albumen. The heart's action was quick and frequent, the pulse small and compressible. The bases of both lungs were congested. The skin, subicteric, and for the most part rough and dry, was here and there, chiefly about the hands and feet, bedewed with watery sweat. The acuteness of all the special senses was blunted; and the patient dull, heavy, and indifferent, could yet be roused to speak, and to answer clearly questions put to him. The temperature of the body at the time of examination in the afternoon was 103°. The story of this case resembled the story of the case first narrated. The patient, supposed to be healthy, but suffering from an affection of the bladder, was, a few weeks before my visit, placed upon the daily use of the catheter, did well for about a week, then became ill, and fell suddenly downward into the condition in which I saw him. Neither Mr. Marshall nor I ventured to form a definite diagnosis of the nature of the patient's malady; but, remembering the case at Haslar, I suggested that the fever, which, we agreed, was not a specific fever, had originated out of the condition begotten by the entrance upon catheter-life. I saw the patient only once. The remedies proposed, the food, the alcohol, the quinine, the aperients, were all of no use to the patient, and he died within a week of our consultation. With great difficulty, permission was obtained to make a post-mortem examination; and although it was made with both care and interest nothing definite was found outside the bladder, and nothing in it sufficient to necessitate or account for death. The prostate was enlarged, the bladder was dilated and thickened. Viewed from the inside, it was trabecular and slightly saccular; the mucous lining was congested, and, in part eroded, and everywhere coated with a greyish-white stinking mucus. There was nothing to be detected in the urethra or in the kidneys, although they were carefully examined. I was accustomed to such examinations, and neither Mr. Marshall nor I could say anything better of the cause of death, than it was due to irritative fever.

WITH TITLE-PAGE AND INDEX.

A Course of Lectures

ON

THE EYE: ITS DISEASES, AND THEIR REMEDIES.

Being an Abstract of a Course of Lectures delivered in the Royal College of Surgeons in Ireland

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
Professor of Ophthalmic and Aural Surgery in the College;
Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 525.)

MUCO-PURULENT ophthalmia is very frequently a complication or a sequela of the exanthematous fevers—small-pox, scarlatina, and measles. The inflammation is simply an extension of the general skin eruption to the conjunctiva, and it partakes of the character of the eruption peculiar to the original disease, presenting the characteristics in scarlatina of simple catarrhal ophthalmia, in measles of a much more decided muco-purulent inflammation, and in small-pox of a severe pustular ophthalmia, of either confluent character, or with distinct pustules. The occurrence of these eye symptoms in connection with the exanthemata marks the fact that the conjunctiva is a modified skin structure, and illustrates the propriety of treating its diseases on the same plan as other diseases of mucous membranes.

It is unnecessary for me to dwell upon the treatment of the simple catarrhal or muco-purulent conjunctivitis, which accompanies measles and scarlatina, for it differs in no respect from the treatment of these diseases where they occur idiopathically, except that leeching and blistering are not applicable. In the pustular form special to small-pox, special precautions are necessary, for there is much risk of the cornea becoming involved in ulceration and presenting cicatrices after the patient has recovered. It has been denied by some authorities that pustules are ever developed upon the ocular conjunctiva

or cornea, but I have myself seen undoubted pustular conjunctivitis accompanying small-pox which could not be confounded with any other disease, unless, indeed, an aggravated attack of phlyctenular ophthalmia concurrent with the small-pox. Bad forms of variola are now happily rare, in consequence of the beneficial influence of vaccination, but twenty or thirty years ago, when a large proportion of the Irish population was unvaccinated, and when small-pox inoculation was rife, the virulent form of the disease was common, and the workhouses were full of the blind victims of the eye disease attendant on it.

In the treatment of this form of pustular ophthalmia, the exposure of the eye to air and light, which is so beneficial in phlyctenular disease, is not suitable. On the contrary, the eye should be covered with a compress bandage, with the view of aborting the pustules and preventing avoidable irritation from the motion of the lids; but the pad should be removed several times, the eye cleaned of discharges, and a very dilute ung. hyd. oxid. flav., not stronger than gr. 3 to the ounce, applied. If the eye be kept continuously bandaged there is a risk of the formation of permanent adhesions or *symblephara* between the conjunctiva of the eye and lid, which, if at all extensive, are fatal to the future usefulness of the eye. As the disease passes off and the pustules are nearly healed, the pad must be thrown off and the usual treatment of the third stage of muco-purulent ophthalmia adopted. These pustules, though I have not seen them develop on the cornea itself, frequently occur on its conjunctival margin and—being deep and extensive—involve the cornea very seriously in purulent infiltration, abscess, ulceration, and even perforation, these being the chief dangers of the variolous form of disease, and resulting in disfiguring opacities, prolapse of the iris, and staphyloma. The occurrence of pustules in this situation must be watched, and if they appear should be made to restrict their dimensions by hot stuping and by opening the pustule the moment the pus shows itself. But, notwithstanding all these precautions, there will frequently remain partial loss of corneal structure and opacity.

A "secondary variolous ophthalmia" sometimes occurs

after the eruptive stage of the disease has passed away, but this is not characterised by the development of pustules. It is a simple muco-purulent ophthalmia, apparently related to the desquamative condition of the skin, and as it does not usually present serious corneal complication a special line of treatment is not needed.

A form of acute conjunctivitis characterised by the deposition of a croupal membrane in patches, must be mentioned, but its symptoms and treatment need not be dwelt upon by me, inasmuch as the disease is almost unknown in Great Britain. I have never myself seen a case in this country, but it is not uncommon in Germany, where it assumes an epidemic character. It differs essentially from the ordinary type of acute conjunctivitis by the absence of the muco-purulent discharge. The lids are greatly swollen, but instead of being soft and oedematous, they are hard, glistening, and very painful to touch. The discharge is sanious, sero-sanguineous, and scanty, and the conjunctiva shows a reddish-grey colour instead of the purple-red villous surface usual in ordinary ophthalmia. These symptoms merge in the stage of resolution of the disease into the symptoms of ordinary conjunctivitis, the lids being soft, the ocular conjunctiva vascular, and the discharge muco-purulent. The disease is more common in subjects of a poor, strumoid constitution, or where there is a taint of hereditary syphilis, and is extremely dangerous, the tendency to sloughing and ulceration of the cornea being greatly enhanced by the obstruction of blood supply arising from the hardness and tension of the conjunctiva. Incisions of the conjunctiva to relieve this tension are comparatively ineffectual, as they do not give exit to the infiltrated matter as they do in cases of ordinary chemosis. The treatment of these cases consists in as rapidly as possible improving the hygienic condition of the patient, and, by the aid of poultices and hot stupes, seeking to restore the circulation which is obstructed by the fibrinous infiltration. The rapid administration of mercury, which is contra-indicated in ordinary ophthalmia, is here necessary, for the purpose of causing the absorption of the infiltrated substance, but the treatment is at best only partially successful, and the progress of the disease is commonly so rapid that the cornea is lost before it is possible to bring the patient under the influence of the mercury.

The forms of ophthalmia which I have described involve the entire conjunctiva, and are true inflammations running a definite course.

Phlyctenular Ophthalmia. Phlyctenular conjunctivitis, or herpes conjunctivalis, is, on the contrary, an affection purely local, and not involving the conjunctiva generally. It is characterised by the recurrent development of minute phlyctens or herpetic pimples, the usual situation of which is upon the margin of the cornea. The attack commences with itching and smarting, which causes the patient to rub the eye constantly; this is attended with a very abundant discharge of tears, and with constantly-increasing photophobia, or intolerance of light, and the attack comes to an end by the phlycten breaking into a minute ulcer, and, after a day or two, healing up, only to be succeeded, *ad infinitum*, by other phlyctens which run a similar course.

The disease is one of low vitality and is almost special to children between the ages of 7 and 17, being never seen in the infant, and very rarely in middle life or old age. It is so commonly associated with the strumoid taint, with enlarged sub-lingual glands and herpetic eruptions about the nose, the angles of the mouth, and the lobes of the ears that it has been, heretofore, called strumous ophthalmia, and with great propriety, treated with iodides and cod-liver oil. When the disease is commencing a small granule of herpetic effusion is seen at the corneal margin to which a bundle of conjunctival vessels is seen to converge, and as the affection progresses the phlycten enlarges and the conjunctival vascularity extends more or less throughout the conjunctiva, but not

to the extent of inducing the muco-purulent discharge of a true conjunctivitis. As the phlycten forms the exposure of the eye to light becomes painful, and when

Fig. 6. Phlyctenular Conjunctivitis.

it has become an ulcer and has involved the corneal margin this photophobia becomes intense and is the chief feature of the disease. The attitude and appearance of the patient are quite sufficient diagnostic signs, and it is difficult to mistake any other disease for this phlyctenular ulceration, photophobia not being developed to the same extent in any other affection. The prognosis of the disease is good, and, as a rule, there is no danger to sight, nor any risk of disfigurement unless the cornea comes to be seriously engaged in the ulceration. In such cases a nebula will remain as the mark of each phlycten, and the accumulation of these slight opacities will eventually injure the sight, or the corneal ulcer may go deeper and perforate the anterior chamber in which case we may have a prolapse of iris and permanent damage to the eye.

The treatment of phlyctenular ophthalmia is above all things hygienic and tonic, and it ought to be well understood that in this disease the depressant and antiphlogistic line is altogether unsuitable and injurious. The only efficacy of the treatment lies in the photophobia which induces—almost coerces—the patient to seek the shelter of a warm and dark room, and to sooth the eye with hot stupes, poultices, and bandages. Such a course contributes materially to the disease, because the confinement to a close atmosphere, and the prevention of personal exercise are certain to add to the low condition of vitality which is the origin of the disease. For the same reason leeching, continued purgation and low diet are altogether injudicious, except when the herpetic ulceration has engaged the cornea and other deeper structures. In such a case, a couple of leeches and a hot sedative stupe may be necessary, and, in any case, a gentle antacid and stomachic aperient will be beneficial at the outset of the disease, but further than this depletion should not go, and to any extent to which this treatment may be carried must be made up afterwards by tonic treatment.

The course which I have found most beneficial generally is as follows:—If the case is seen when the phlycten is forming, give at once the mercury and chalk powder, which I have already suggested for incipient conjunctivitis, and accompany it with a quinine mixture. I find the compound tincture of bark with three grain doses of iodide of potassium very efficacious where it is desired to bring the system rapidly under tonic influence. At the same time, the dietary should be looked to, and made abundant and nutritious. For young subjects I prefer farinaceous food, such as porridge and corn flour and rice, abundance of milk—if digested—and also eggs, chicken, fish, and a little underdone fresh meat are useful, but I would not force an abundant meat dietary.

The idea which the average mother has of a generous diet for a child is a cup of beef-tea with plenty of arrowroot or jelly, none of which nutriments will to any extent supply the place of milk, eggs, and well cooked oatmeal. Beef-tea is entirely unobjectionable, and as a help to other means of alimentation it is useful; and the same may be said in a less degree of arrowroot, sago, tapioca, and other starch foods and of jelly, which is usually nothing better than a pinch of gelatine dissolved in water and nicely flavoured.

If the photophobia becomes intense, and after-ulceration

of the phlycten has taken place, it may be desirable, for the sake of keeping the eye at rest and preventing friction, to apply a wet compress and bandage over the eye, but the sooner it can be dispensed with the better, because the photophobia is greatly increased by keeping the retina in darkness, and therefore such light as can be borne should be admitted. For this reason the patient should not remain in bed beyond usual hours, and should on no account be permitted to lie on the face, or keep the eyes covered with band or handkerchief; or, if a child, to lie face downwards on the nurse's shoulder when carried out of doors. When at all possible the child should sleep in a cot by itself with not too much covering, and no curtains. The ventilation of the room should be abundant, and the light moderate, and the patient's eyes will be sufficiently guarded by sitting in a distant corner with the back to the light. In fact, fresh air, exercise, and moderate light act as a charm in these cases, and should be had every day, and all day if possible. There is no special risk to the eyes from catching cold, and therefore, even in unfavourable weather, the patient should go out—walking exercise being preferable to driving in carriages or cabs. To obviate the disposition to lie face down on the nurse's shoulder, or to keep the hand up to the eyes, the child—if able to walk—should be led by a person holding each hand, and allowed to rest by sitting down from time to time. The first day of this treatment will be painful, but each day of perseverance afterwards will show a decided improvement until the patient is perfectly well.

This photophobia may be, in some degree, alleviated by special local treatment, of which the installation of a three grain neutral solution of sulphate of atropia (a) is most favoured.

I cannot say that I have much confidence in atropia as a sedative, but I know that it is liable to increase the photophobia by admitting a flood of light to the retina through the dilated pupil. I shall, however, speak of the use of it and of eserine further on. I prefer the old-fashioned vinum opii, which I have found to be powerfully sedative in all irritable ulcers, sufficiently astringent and stimulant and not too irritating. When the ulcer is open, and is slow to heal the application of calomel upon its surface is very useful, but it must be done properly or not at all, or if a quantity of it is left within the lid it causes much irritation. It is also by no means easy to apply it effectually, as the photophobia makes it almost impossible to expose the cornea. The only way to manage it effectually in the child, is to put the head between your knees—the hands and legs being controlled by an assistant—and to raise the lid with a speculum. The point of a dry camel's hair brush being dipped in the dry calomel powder, the brush should be held horizontally between finger and thumb, and the brush filiped sharply with the third finger, so as to jerk the powder upon the ulcer surface.

If, after the ulcerations have healed up, a chronic conjunctivitis remains, it may be cured by brushing the lid with a ten grain solution of silver nitrate and by Pagentecker's ointment, for which I have already given a formula. The constitutional treatment is all important, and the hygienic treatment, to which I have already referred, should be supplemented with a long continued course of iodide of iron. A teaspoonful of equal parts of syrup. ferri iodide and syrupus cinchonæ thrice daily is suitable, but, in dispensary practice the less expensive simple syrup may be substituted for the syrup of bark, with sacrificing much of the efficiency of the mixture. This should be continued for at least six weeks, and the patient should be reminded that occasional relapses are to be expected before the disease is finally got rid of.

- (a) $\mathfrak{B}$ Atropinæ sulphatis, 3 gr.;
Acid. sulph. dil., 8 gt.;
Aq. rosar. ad $\mathfrak{ss}$;
Ft. collyr.

The dilute sulphuric acid is added to ensure solution of the atropia salt, and the rose water being made of distilled water is suitable. The liq. atropiæ of the Pharmacopœia contains spirit, and is painful and irritating to use.

CATHETER FEVER. (a)

By SIR ANDREW CLARK, BART., M.D., LL.D.,
Physician to the London Hospital, &c.

SOMEWHERE about the year 1850, one of the medical officers of Haslar Hospital (who, I dare say, will be kept in remembrance by my former messmate, Sir Joseph Fayer), between fifty and sixty years of age, of nervous constitution, but apparently in robust health, requested me to examine his urine. Accordingly, I submitted it to as careful an examination as I was then competent to make, and all that I could find out against it was, that it was too great in quantity, too low in density, and too pale in colour. He then informed me that he had trouble with his bladder, that he meant to consult Sir Benjamin Brodie, and that he wished me to accompany him for that purpose to London. Sir Benjamin examined his patient, drew off a large quantity of urine from the bladder, told him he was suffering from simple enlargement of the prostate, prescribed the regular use of the catheter, and with a few general cautions against a careless diet and exposure to cold he quickly but kindly dismissed us both. We returned to Haslar. In about a week, the patient was free from local discomfort, and without complaint of his general health, but then he began to feel and to look ill. He complained of *malaise* and weakness, and of general pains. He lost his appetite; was tormented by thirst; had nausea; became feverish; took to his bed; got daily worse; and, notwithstanding the efforts of his colleagues, who could not agree as to the nature of his malady, he died in about three weeks from the beginning of his illness. No post-mortem examination was allowed. The case here so imperfectly narrated made upon my mind an impression which has never been effaced; but, until about the year 1865, I saw no other case exactly resembling it.

In that year, I was summoned by Mr. Peter Marshall to visit a gentleman suffering from fever. Certainly he was in what is called vaguely amongst our elder brethren, a typhoid state. He was between fifty and sixty years of age. He was lying on his back in bed, apparently in a state of great prostration. The face was faintly yellowish and mottled, the lips dry, the pupils dilated, and the breath fetid. The tongue was small, brownish red, dry, tremulous; there was complete anorexia. The bowels had been imperfectly relieved. The urine, habitually removed by the catheter, was low in density, acid, and deposited on standing, a little muco-pus, and contained a small quantity of albumen. The heart's action was quick and frequent, the pulse small and compressible. The bases of both lungs were congested. The skin, subicteric, and for the most part rough and dry, was here and there, chiefly about the hands and feet, bedewed with watery sweat. The acuteness of all the special senses was blunted; and the patient dull, heavy, and indifferent, could yet be roused to speak, and to answer clearly questions put to him. The temperature of the body at the time of examination in the afternoon was 103°. The story of this case resembled the story of the case first narrated. The patient, supposed to be healthy, but suffering from an affection of the bladder, was, a few weeks before my visit, placed upon the daily use of the catheter, did well for about a week, then became ill, and fell suddenly downward into the condition in which I saw him. Neither Mr. Marshall nor I ventured to form a definite diagnosis of the nature of the patient's malady; but, remembering the case at Haslar, I suggested that the fever, which, we agreed, was not a specific fever, had originated out of the condition begotten by the entrance upon catheter-life. I saw the patient only once. The remedies proposed, the food, the alcohol, the quinine, the aperients, were all of no use to the patient, and he died within a week of our consultation. With great difficulty, permission was obtained to make a post-mortem examination; and although it was made with both care and interest nothing definite was found outside the bladder, and nothing in it sufficient to necessitate or account for death. The prostate was enlarged, the bladder was dilated and thickened. Viewed from the inside, it was trabecular and slightly saccular; the mucous lining was congested, and, in part eroded, and everywhere coated with a greyish-white stinking mucus. There was nothing to be detected in the urethra or in the kidneys, although they were carefully examined. I was accustomed to such examinations, and neither Mr. Marshall nor I could say anything better of the cause of death, than it was due to irritative fever.

(a) An Address delivered at the last meeting of the Medical Society of London, Monday, December 17th, 1883.

The study of this case gave birth to the opinion (now a confirmed belief) that the entrance upon catheter-life occasionally gives rise to a pernicious fever, which, in the majority of instances, destroys life, and is sometimes, without the intervention of any sensible structural change, sufficient to account for death. Since 1866, every year has added to my experience of such cases; and, for over ten years at least, I have been in the habit of mentioning them to surgeons with whom I have had the privilege of consulting. From Sir James Paget, and especially from Sir Henry Thompson, whom I have often met in such cases, I have received at various times much important information; but as I have received from neither of these distinguished surgeons explanations completely in harmony with my own experience and views of such cases as the one just narrated, and as further information might be now in their possession, or in the possession of others, I ventured, upon a recent occasion, at the Clinical Society, to mention the subject in the way in which it has occupied my thoughts, and to invite from my surgical contemporaries their latest experiences and conclusions concerning it. The constitution of the Clinical Society did not permit abstract questions of this kind to be discussed, and my object was not to offer, but to receive, information. My remarks, finding a place in the medical journals, and being by them widely disseminated, have elicited from practical surgeons in all parts a variety of interesting and instructive communications concerning the nature and causes of the fever which occasionally follows casual or habitual catheterisation. Nevertheless, as the exact character of those remarks which I made has been, doubtless by my own fault, misapprehended, and as the subject is of such importance as not only to justify, but to require, the statements made respecting it should be accurate and clear, I gladly, as I have said, comply with the request conveyed to me from various quarters to re-open the subject. Now, sir, it is not my intention on the present occasion to narrate a series of cases and to build thereon a dissertation upon what, for the sake of provisional convenience, I have called catheter-fever. I have not, indeed, at my command the materials necessary for such an undertaking; and if I had, devoid as I feel myself to be of the enlightenment and strength which flow out of the surgical instincts begotten by long surgical experience, I would not attempt it. I have seen many cases of catheter-fever, but I have never had charge of one. I have visited my cases only occasionally, and in consultation with other practitioners; and almost always my colleagues have been too busy to keep and to furnish me with minute and continuous records. Indeed, from the present temper of the public mind, the fear which patients have of being made the subjects of experiment, and the demands so thoughtlessly and even cruelly made upon a practitioner's time, it has become increasingly difficult to keep clinical records of any case for oneself; and the public, in what I must call its vicious stupidity, is thus hindering us from helping it so well as, otherwise, we might have the power to do. But, although my records of individual cases of catheter-fever are thus, from the necessity of the case, incomplete, I venture to think that, both by the study of their salient characteristics and by the questioning of those in charge of them, I have learned at least enough of their nature and importance to justify me in making certain propositions, and in asking certain questions concerning them. The statements which I propose making about this catheter-fever will be most conveniently embodied in a short series of propositions. But, before submitting them to your consideration and criticism, it will be necessary, in order to obtain a clear and comprehensive understanding of the subject underlying them, to discover the origin and to follow the historical development of those ideas which have shaped the theories of surgeons and determined their lines of practice.

I have here a table, which, I regret to say, is imperfect. It is a table prepared by my assistant, Dr. Delépine, who has devoted to it most careful study and most conscientious care; and it has, on account of the deficiency of indices to books, occupied an amount of time and caused a degree of labour which you can scarcely imagine. I shall have it, for further purposes, completed. In the meantime, it will enable those who do not follow me closely in reading to determine for themselves the order and development of the ideas which have been promulgated concerning this subject. I shall not, in my retrospect, follow as minutely as is here followed the development of these ideas; but I shall take the leading ideas; for, by holding to these leading ideas alone, I think we shall be able to survey the whole field.

In 1800 it was known, but not distinctly expressed, that surgical interference with the urethra and bladder was sometimes, and in certain circumstances, followed by an irritative fever. It was not, however, until 1810 that Moffatt, as quoted by Velpeau, described a case of stricture of the urethra, in which simple catheterism was followed by rigors, irregular fever, purulent arthritis, as it is called in France, and death. In 1832, ideas concerning the casual relationship of catheterism to consecutive fever first found form and expression in the writings and teachings of Brodie and Velpeau, and perhaps of Civiale. Brodie distinctly, and even emphatically, mentions the dangers of catheterism, and describes as occasionally occurring in consequence of it, paroxysms of irregular fever—like ague, and leading sometimes to prolonged debility, sometimes to continued fever, with rheumatic pains, and sometimes even to mania. He further says that, in such cases, death may follow, but he cites no case of its actual occurrence. Velpeau enters much more minutely into the nature and relations of the fever thus mentioned, and contributes several new ideas to the further development of the subject. He alleges that in some persons, perfectly healthy, not malarious, not exposed to its influences, even easy catheterism may develop a consecutive and continuous fever, and that this fever has five varieties. In the first it consists of a single paroxysm of fever, ending in *malaise* and debility, with recovery in a few days. The second consists of recurring paroxysms of fever, issuing in continued fever, and oftentimes fatal. The third consists of an inflammatory fever arising out of nephritis, phlebitis, and other local inflammation. The fourth consists of fever, associated with purulent arthritis. The fifth consists of a rapid succession of violent paroxysms of fever, speedily ending in collapse and in death. Velpeau then points out, and very clearly, that in the second and fifth varieties he has never found present at the necropsies any adequate structural cause of death, and in these cases he is disposed to regard the origin of the fever as caused by the re-absorption of vitiated urinary constituents. But on this, and indeed on similar points of pathogenesis, he is both obscure and vague. Civiale, whose great work is disfigured by passionate claims of priority in this matter (of which claims he furnishes no proof), and by the satirical invective which he launches against the juster and greater Velpeau, gives a full and admirable description of this catheter-fever; but, whilst admitting that the fever is due sometimes to the urethra, and sometimes to the bladder, and contending that the fever of the one differs essentially from the fever of the other, he almost angrily minimises the effects of surgical interference, and it would seem as if with a judgment disturbed by emotion, contends that in most cases the fever has existed before the use of the catheter, or that it is due to nephritis (*a*).

But in the latter part of Civiale's work, marked by greater sobriety of language and a more judicious tone of argument, (page 612, ed. 1860), he distinctly qualifies these strong assertions, changes his point of view, and says that the cause of fever is vague and uncertain, and that, in speaking of its nature, we can only guess.

In 1858, Mr. Phillips contributed some farther ideas concerning the conditions under which this fever is developed. Describing the fever, and in the main following the classification proposed by Velpeau (who, it may be remarked, is the source whence almost all subsequent writers have derived their inspiration, and sometimes, without acknowledgment, their ideas), he asserts, first, that the simplest as well as the severest catheterism, with the largest or the smallest instrument, may originate the fever; secondly (and this is the most important contribution, if it be a true one, which he has made), that, unless the affection of the urinary passage lies behind the bulb, the fever does not follow; and, third, that the predisposition to the fever does not lie in the state of the nervous system at all, but in the existence of certain diathesis and in chronic disorders of the general health.

In 1859, Marx, in a monograph of remarkable merit, reviewed the state of the question at his time, and contributed to its elucidation and development certain important facts and ideas, expressed with great clearness and used with judicial ability. He adopted a classification of the varieties of catheter-fever similar to that given by Velpeau; recog-

(a) I owe to Dr. Matthews Duncan my best thanks for a letter, in which he tells me that he himself has listened to Velpeau setting forth the characters of this very catheter-fever to which I am calling attention.

nised uncomplicated cases issuing in death without any discernible structural lesion outside the bladder, quoting eight or nine that occurred in his own experience; asserted that it may occur in persons of perfect health; and that, in them as well as in others not healthy, it may follow upon any state of the urinary organs requiring the passage of a catheter; and, finally, he declared with emphasis the fever to be positively uræmic, and ascribed its origin to insufficiency of the kidneys arising out of functional or of structural disease. In this work, perhaps for the first time, the casual relationship of catheterism to catheter-fever was most clearly and comprehensibly set forth, and a logical, coherent, and ingenious, if not accurate, theory of the genesis of the fever was propounded.

In 1867, the practical, and indeed, also, in some respects, the theoretical, aspects of this subject were greatly advanced by the publication of the now classical work of Sir Henry Thompson, on the urinary organs. In this work, characterised by great force, method, clearness, precision, and knowledge, he mentions the perils of catheterism, gives instructions for averting them, notices the occurrence, in a few exceptional cases, of a low, irritative fever, and quotes Sir Benjamin Brodie to show that, in a few weeks, it might terminate in death. But, furthermore, he says (and here he differs from almost every one of his predecessors in this line of inquiry), that in all such cases there will be found old-standing pyelitis, with dilatation and marked degeneration of the renal structures, and that in no circumstances could such patients long survive. Looking at the unrivalled experience of this distinguished surgeon, and remembering how often I myself have consulted with him about cases such as this that I am now considering, I confess to a feeling of disappointment that he has not made time to give to the profession a more serious and adequate account of this important matter, which he must know better than almost any one else.

In 1867 the distinguished President of this Society, Sir Joseph Fayrer, gave an admirable account of the varieties of catheter-fever; declared, if I understand him aright, that the predisposition to it lay in the malarious state and its consequences, or else in incipient or advanced disease of the kidneys or other parts of the urinary tract; that it began (and from him we have, for the first time, a clear and express statement on this point) in reflex disorder of the nervous system; that it was not toxæmic; and that catheterism alone, without injury or sensible irritation, was in these circumstances sufficient to originate the febrile phenomena and process. In 1868 Sir James Paget notices this fever, and makes some remarkable additions to our knowledge of it. He says that, when the urine is of low density and abundant; when the patient is gouty, dyspeptic, or otherwise chronically disordered; when, having a stricture, it becomes irritable, and weakens the health; or when, being old, something has occurred to cause temporary depression of the health, catheterism will be especially dangerous, and may bring about a fever, ending in death. He leans to the opinion, although he does not distinctly express it, that renal degeneration is the cause of the fever, but admits that, so far as his own experience goes, the cause is apparently inadequate. Lastly, he states that the mortality of such cases is from three to four per cent.; which, even with my grave views of the subject, is a much higher ratio than my own experience would have led me to expect.

In 1871 Mr. Banks, of Liverpool, describes the effects of simple catheterism, and classifies them into three varieties—first, rigor, with *malaise*, recovering speedily; second, rigor, with *malaise* and prostration, followed in a few days by fever and death; and, third, cases of shock, producing death within sometimes a single day. Admitting that renal disease predisposes to such attacks, he denies that they are due to suppression of urine, and ascribes them to shocks of greater or less severity propagated through the sympathetic nervous system. Here the nervous theory begins to preponderate over the other. In 1873 Malherbe, in his work on the fever of diseases of the urinary passages, presents a fairly just account of the state of our knowledge of this subject at the time of publication, and he adds certain important cases of his own. These cases are illustrated by a number of interesting and instructive temperature-charts. He avers that the fever may arise without local irritation; describes it as uræmic; alleges that the predisposition to it is renal; and whilst admitting—may, giving evidence of the admission—that in some cases, not a few, no structural

lesions are found after death, he yet holds to the hypothesis that the origin of the fever is in renal imperfection. In 1877 Mr. Marcus Beck contributed to the further elucidation of this subject two important papers bearing upon them the marks of practical knowledge, accuracy of observation, and careful thought. Describing the fever in which death may occur in from nine to forty-eight hours (and not, as I found, noticing the longer fever of which I speak), he holds that the predisposition to it lies in chronic disorders of the health, in renal imperfections, and in age; that the exciting cause is probably mechanical irritation or lesion of the urethra, and that the fever is begotten through irritation of the spino-cerebral and sympathetic nerves, reflected upon the kidney, and bringing about structural or other insufficiency thereof. Beck strongly supports the hypothesis that the fever is uræmic, but plainly his views are based on the study of old worn-out hospital cases.

Now, without carrying it further, it will be seen from this rough historical retrospect that catheterism is occasionally followed by a fever which has received the various names of urethral fever, urethro-vesical fever, urinary fever, uræmic fever, catheter fever, and so forth; that, in some cases, this fever is dependent upon, or associated with, purulent arthritis, ordinary pyæmia—what is known in England as surgical kidney, or interstitial nephritis—and that, in a small, but still noticeable percentage of cases, no adequate structural cause of death has been found. Now, it was of this last variety of fever that I spoke upon a recent occasion at the Clinical Society, and it was of this variety alone that I made, or mean to make, the following propositions.

First, about middle life in men perfectly healthy, or with no discoverable evidence of disease, except, perhaps, and even then not always, a low density of urine, the commencement of the habitual use of the catheter is sometimes followed by fever of the remittent type, which often ends in death; and, for the fatal issue in such cases, no adequate structural explanation can be found.

Secondly, it is important that such a fever arising in the midst of apparent health from such a seemingly small cause, and leading so often (as it certainly does), to a fatal issue, should be well and widely known, lest death should take the friends of the patient by surprise, and arrangements necessary to the welfare of a family should be left unmade.

Thirdly, although it is well known that in persons affected with renal disease, or in chronic gout, or with grave disorders of the general health, the commencement of habitual catheterism is attended with peril to life from secondary fever, the fact that this fever may arise in what seems to be good health, and, without the mediation of any visible structural lesion, issue in death, is not well known, or at least well known only to a few, and has, I repeat, no adequate place in English surgical literature, or in the English surgical teaching of this time. Of course this knowledge will be found, as I have in a very imperfect way shown you, in special monographs, and papers; but those are the luxuries of the few, and, for the most part, the luxuries of specialists who work in that direction; but such knowledge should be, as I think, fully imported into all common text-books, and so made accessible to the whole body of the profession.

Fourthly, this fever is neither distinctly uræmic nor distinctly pyæmic; although having some of the characters of each, it has all the necessary characters of neither. Probably it begins in the nervous system. Probably the disturbance of the nervous system reacts, in the first instance upon the general metabolism of the body, and, in the second instance, upon the secretory organs, beginning with the kidney. The effect upon the kidney may consist either in structural alterations of the kidney, invisible by the aid of our finest instruments of research, or, as seems to me much more probable, in alteration of the constitution of the blood, the dynamic condition of its constituents in the renal vessels essential to the elaborative action of the secretory cells thereof; and lastly, the concurrence of these conditions may, and often is, enforced by septic re-absorption into the blood.

Fifthly, a more complete knowledge of this variety of fever and of the conditions of its origin, maintenance, and increase, may, at least we may hope, lead to a material diminution of its mortality; and, even now, by treating in a serious manner entrance upon catheter-life, by taking the

precautions set forth by Sir Henry Thompson, by great temperance in the use of foods and stimulants, by rest, warmth, and by other general means upon which I shall not dwell, such mortality, I repeat, may be possibly considerably diminished.

Of these five propositions, the one at the present moment most open to attack is the fourth, wherein it is asserted that this fever is not distinctly and exclusively uræmic. For, in these days, it has come to pass that almost every writer of distinction adheres to the view of the uræmic origin and nature of catheter-fever, or the thing known under that and other names, and I am, as it were, left by myself very imperfectly armed to oppose it. I oppose it. I ground my opposition to the exclusively uræmic theory upon the fact that the phenomena of catheter-fever, not as they exist at a particular moment, but in their assemblage and in their progress together, are different from those of the ordinarily recognised uræmia. The duration is at once longer and shorter—longer than that of acute uræmia, and wanting its headache, its perversions of sensation, its changes in the urine, its convulsions, its profound coma; shorter than that of chronic uræmia, wanting its neuralgias, its recurring headaches, its defects of sight, its itchings of the skin, its vomiting, its characteristic breath, its attacks of dyspnoea and palpitations, its painful nervousness, its low temperature. Furthermore, the urine of the catheter-fever—of this variety, at least, of catheter-fever—is always loaded with micro-organisms of various kinds; and although it is deficient in urea, and contains more or less albumen, it deposits no tube-casts, and it is capable of amendment. Lastly, while chronic uræmia issues in death, catheter-fever may issue—sometimes does issue—in complete recovery. Sir Henry Thompson may remember that I saw with him a distinguished nobleman, not far from Oxford Street, who had to make an entrance upon catheter-life; and he very justly and wisely warned the relations that it was a serious procedure, and that he might suffer constitutional disturbance after the starting of this mode of life; and it happened that he did suffer this constitutional disturbance. It happened, indeed, that he had a mild variety of this fever which I am describing, and that it continued between a fortnight and three weeks. Eventually, with Sir Henry Thompson's help, he recovered; and I think I may say now—five, six, or seven years afterwards—he is in good health at an advanced age. Except in its long duration, in its occasional rigors of great severity, and its exceptional clearness of mind, the phenomena of what is called endocardial fever resemble more nearly those of the fever which I have called for the moment catheter-fever than any other malady with which I am acquainted.

Two questions of a practical kind arise out of this study of the history of catheter-fever. Seeing that by almost universal assent the fever originates at least in a disturbance of the nervous system, and seeing, furthermore, that in the cases accessible to me, at least, there is no account of the fever following in cases where narcotics or anæsthetics have been used, may it not be that the fever is capable of being cut short by the administration, on entering upon habitual catheterism, of narcotic or anæsthetic remedies? I remember that my great master, Syme, in Edinburgh, with a reason which his instincts very often knew better than his understanding, invariably gave his patients, whom he had to catheterise, opium, frequently a grain or two from the very beginning, and I must also add that he was singularly free from catheter accidents. The second question is this: Assuming the presence of the fever, and seeing that quinine has signally failed in controlling it, what are the drugs to be employed on such occasions, and what is the sort of hygienic management to be followed, especially in respect of food and alcohol, which are so variously used on such occasions, in order that the fever may be brought, if it be possible, to a successful ending?

Such, then, are the main conclusions which I have drawn for my fragmentary studies of this form of catheter-fever. I know that they are incomplete; I even fear that they may be inaccurate; but however this may be, I submit them to your consideration, and I console myself with the reflection that they may call forth the ripened experience of practical surgeons, who, in this matter, furnished with a larger knowledge and a more practised judgment, may be able not only to correct me where I am in error, and to confirm me in any small point where I may have caught the truth, but to supply us with the very knowledge which at this juncture we need and ask.

Clinical Records.

EDINBURGH PROVIDENT DISPENSARY FOR WOMEN AND CHILDREN.

Two cases of Peliosis Rheumatica.

Under the care of Dr. S. JEX-BLAKE.

THIS affection, first described by Professor Schönlein ("Pathologie und Therapie," vol. ii.), appears to be so rare in this country that its existence, at least in well marked and distinctive form, has been denied by some more recent authors. Some interest may, therefore, attach to a short account of two cases that occurred in my dispensary practice last winter, both of them appearing, curiously enough, during the same month.

CASE I.—G. R., a nursemaid in good service, æt. 16, applied for advice on Dec. 12th, 1882. She had a sore throat, with inflamed tonsils, and also suffered from severe coryza, but was much more alarmed by a rash which appeared plentifully over the whole surface of her lower limbs, but did not extend to the upper part of the body. It consisted of purplish petechiæ, of small but irregular size, and the general effect resembled that which might have been produced by spattering the legs with a brush charged with rather light-coloured ink. The pulse was about 100, temperature only slightly above the normal, and the previous night's sleep had been pretty good. I sent the patient at once to bed, and treated her for the sore throat and cold without any special reference to the rash.

Dec. 19th.—The patient's mother reported that the sore throat and cold had almost disappeared, but that the rash continued much the same, and that some distress was caused by pains in the legs, apparently of a rheumatic character. Salicylate of soda was then given in the ordinary doses.

In about ten days the pain and the rash had both disappeared, and when I saw the patient next, on January 16th, she was perfectly well.

CASE II.—G. B., a schoolboy, æt. 9, was brought by his mother, on Dec. 26th, 1882, for treatment for swelling and pains in the legs, and on inspection a plentiful rash, almost exactly resembling the one previously described, was found on the lower limbs, and, as in the former case, on these only. His pulse and temperature were about normal, and his general health good. The history of this case was more distinctly rheumatic, as the starting-point of the illness seemed to be exposure to cold and wet during a snow-storm, encountered on the way to school, after which the boy sat in damp clothes during the time of study.

He was treated with salicylate of soda, and a week later the eruption had much diminished, but the pain, though relieved, had not disappeared. I then advised his mother to give him a diet of fruit and vegetables, instead of meat, and the dose of salicylate was somewhat increased.

Jan. 5th.—The pain had gone, and the rash was fast fading.

19th.—The rash had entirely disappeared, and there had been no return of pain. The salicylic treatment was now given up, and some cod-liver oil ordered with Parriah's syrup of the phosphates.

30th.—A few spots had re-appeared, but faded again without any special treatment.

Feb. 13th.—Returned to report himself perfectly well.

Within the last few weeks (December, 1883) inquiry has been made respecting both patients, and it has been ascertained that in neither case has any relapse occurred.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 29, Bombay 22, Madras 39, Paris 24, Brussels 25, Amsterdam 30, Rotterdam 23, The Hague 18, Copenhagen 26, Stockholm 22, St. Petersburg 29, Berlin 24, Hamburg 26, Dresden 26, Breslau 31, Munich 27, Vienna 25, Prague 32, Buda-Pesth 27, Rome 27, Turin 25, Venice 28, Lisbon 27, New York 22, Brooklyn 18, Philadelphia 20, and Baltimore 18.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND. PATHOLOGICAL SECTION.

A MEETING of the Pathological Section was held at the Royal College of Surgeons on Friday evening, Nov. 30, Mr. A. H. CORLEY, F.R.C.S.I., President of the Section, in the chair.

Dr. E. H. BENNETT, Hon. Sec., read the minutes of the previous meeting, which were confirmed.

PSEUDOGLIOMA.

Mr. JOHN B. STORY exhibited an eyeball removed from a boy, aged eight months, for inflammation in the interior of the globe. Numerous microscopic preparations were shown demonstrating the pathological distinctions between this disease and glioma retinae, of which three undoubted specimens were exhibited for purposes of comparison. Mr. Story agreed with most authorities in holding that in some cases where the diagnosis was so difficult it had to remain for a time at least uncertain.

Mr. SWANZY said that, as he understood the case, it seemed to be one of the spontaneous formation of pus in the interior of the eyeball—a purulent infiltration of the interior of the eyeball, starting from the choroid. That being so, the specimen was rather a rare one; for according to general experience, such an occurrence was connected in some way with septic disease, the direct result of a wound or injury to the eyeball; or with septic blood disease. They knew that this purulent choroiditis might occur in cases of metria, or of septicaemia after surgical operations, and from other causes. It also occurred in cerebro-spinal meningitis. He was not aware of any instance in which it had occurred spontaneously. It was hard to understand how it should. He had never seen a case of purulent choroiditis in connection with vaccination after inflammation; but he had seen affected eyes that seemed to be the result of purulent infiltration of the choroid, and in cases in which he learned that there had been inflammation of the arm after vaccination. It was easy to understand septic matter being carried from the arm to the vascular coat of the eyeball.

Dr. ARTHUR BENSON said there had been great difficulty in making an exact diagnosis. Before the eyeball was extracted there was so much inflammation that he was of opinion it was not true glioma. On enucleating the eyeball it was found that the inflammation had extended to the orbit, and that there was further disease all round; so that it seemed as if the case was one for more or less dissection; but it turned out that there was only a thickening of the tissues, and no protrusion of anything through the sclerotic.

Mr. STORY, in reply, said that the occurrence of spontaneous suppurative hyalitis or choroiditis was very rare; but he did not see why it should be impossible for pus to originate in the eye any more than elsewhere. Spontaneous suppuration had occurred in other places in the same child, and there were spots on the skin. The occurrence of spontaneous suppurative hyalitis was not, however, a thing unknown; for in a paper published in the last number of the Transactions of the Ophthalmic Society, Mr. Nettleship recorded several cases of pseudoglioma, and Mr. Brailley, in Guy's Hospital Reports, recorded the occurrence of spontaneous suppurative hyalitis and spontaneous diffuse morbid changes of the eyeball. One of the reasons for enucleation in the case in question was the fear lest the second eye should become implicated.

PERVIOUS URACHUS, WITH REMARKABLE DISEASE OF BLADDER.

Dr. C. B. BALL exhibited specimens taken from a patient *et. 10*. Twenty months previously to his death the patient was admitted into Sir Patrick Dun's Hospital suffering from incontinence of urine. He had frequent attacks of hæmaturia. The water was alkaline, and contained considerable quantities of pus. Sounding gave negative results. These symptoms subsided under the treatment, and he was discharged, but was readmitted January 13, 1883, with urine flowing from the umbilicus, none coming by the urethra. His mother stated that three weeks before his re-admission a small gathering had formed at the umbilicus, which broke, and since then all the urine had come by the abnormal opening. Attempts to pass any instrument through the urethra into the bladder having failed, a laminaria tent was placed in the umbilical opening.

This was followed by dribbling of urine from the urethra in three hours, the first that had passed naturally for seven weeks. A catheter could now be passed without difficulty, but not retained in the bladder. Canterisation of the umbilical cicatrix with a subcutaneous ligature passed round the umbilicus when granulation was established closed the opening for ten days; but fresh suppuration supervening, the fistula reopened. A further and more extended canterisation was again followed by closure. The bladder now to a certain extent regained the power of holding water, it being noticed on one occasion that he retained his urine for two hours. Three weeks subsequently, without apparent stoppage of the urethra, the umbilical orifice reopened, urine now flowing by both channels. A plastic operation was performed, and a progressive occlusion of the abdominal opening took place. This continued intermittently for two months, and he was discharged on Oct. 15th. On Nov. 18 he was seized with peritonitis, and died the same day. A post-mortem examination was held. Upon opening the abdomen a small quantity of fluid was found in the peritoneal cavity, with abundance of recent lymph. The omentum was adherent to the front abdominal wall, apparently as the result of old-standing peritonitis. The bladder was much contracted, and the walls increased in thickness. Springing from the fundus was an elongated tongue-shaped cavity, reaching up to a level with the umbilicus, measuring $2\frac{1}{2}$ in. by $1\frac{1}{2}$ in. Upon opening the bladder a number of new growths were found, resembling in appearance the columns carnae of the heart. Some were attached by one extremity only, others by both ends, a space being left between the side and the wall of the bladder. They also frequently intersected. The microscopical examination of these growths showed them to be composed of fibrous tissue covered with mucous membrane. There was no evidence of true papillary structure. The obstruction to the urethra was caused by a septum attached posteriorly immediately below the opening of the ureters, and stretching to the front wall. This was divided in opening the bladder. Springing from the fundus, the cavity before mentioned communicated with the bladder by a large opening, and its walls contrasted markedly with the bladder walls, being exceedingly thin and smooth on the surface. In the front of this, two openings communicated with the peritoneal cavity, by means of which the fatal extravasation took place. A microscopical examination of the wall of this cavity showed it to be lined with mucous membrane, thus demonstrating the fact that this was a case of dilated urethra. The ureters and kidneys presented appearances of long-standing bladder destruction.

The PRESIDENT said he saw the case while the patient was in hospital, and seeing now the result of the post-mortem, he did not quite agree in the opinion that the urachus was completely obliterated. Obstructions in either the bladder or the urethra had such a degree of force that they would enlarge an unobliterated urachus.

Dr. BENSON said Dr. Ball's case reminded him of one of a man in the City of Dublin Hospital who came there for a chest affection. Whilst in hospital he directed attention to a small lump about an inch below the umbilicus. It got larger, grew soft, and was opened. The man died of chest disease and kidney disease combined; and they traced an abscess backwards into the cavity of the abdomen, and found that it originated in the apex of the wall of the bladder. The abscess had evidently commenced in a very backward part of the wall of the bladder. He was doubtful at the time whether it could be ascribed to the urachus or not. He searched for the urachus at the time, but found no trace of it.

Dr. BENNETT observed that this case had a greater surgical than pathological interest; but the Section was of course limited to the latter view. The difficulty of diagnosis in such cases was extreme. He had seen the case with his colleague from the beginning, and he could not arrive at anything like a satisfactory diagnosis of it. The extreme freedom with which a probe passed in the first instance suggested the possibility of a pervious urachus. The great practical point was that, notwithstanding that, in other respects, the boy was in comparatively good health, yet, whether surgical interference was resorted to or not, his life hung on a thread. Although trifling external conditions were presented, the case might have become disastrous at any moment by rupture.

Mr. STORY thought Dr. Ball had laid too much stress on the supposed existence of a membranous diaphragm in the bladder. He said that in the early part of the case he could pass a probe through the umbilicus and a catheter through the urethra. If a membranous diaphragm had been there he

could not have done so. Possibly the membranous diaphragm was only of partial extent.

Dr. BALL, in reply, said that where an obliteration represented the urachus there was some trace of a mucous membrane to be found in the middle of it. He did not mean to convey that that was pervious. The first time the boy was brought to the hospital great difficulty was found in passing the sound, his first attempt to do so being a failure. But Dr. Bennett succeeded in passing a sound by depressing the handle. Afterwards he passed a catheter through the urethra, and a probe through the urachus, and made them touch.

CYSTO-SARCOMA OF THE BREAST.

Dr. BENNETT exhibited and described a cysto-sarcoma of the breast. He said the specimen had been in the strongest spirit since last June, and had shrunk so much that a very imperfect idea of its original dimensions could now be formed. The drawing exhibited of a similar tumour taken from a patient of the late Dr. Rawson, of Carlrow, exactly represented the original condition of the specimen under notice. In Dr. Rawson's case the tumour weighed 13 lbs.; the present specimen weighed 14 lbs. As far as he could ascertain, the patient suffered from it about six years. Her age was between 43 and 44. In every other respect she was healthy. The tumour had been noticed from the first as a changing one; but she had never suffered the smallest distress from it, save by reason of its weight. It first appeared as an irregular lump on the breast, and afterwards grew irregularly, sometimes remaining quiescent and at others enlarging. During the last two or three months its weight became so cumbersome that she applied for advice. The name of the tumour was that adopted by Müller—cysto-sarcoma phynodes. It had branching masses passing through it, and the whole of their surfaces were covered with epithelium of the mammary ducts. The pectoral muscle was so intimately adherent to and absorbed by the tumour that it was impossible, in removing the tumour, to save the muscle. The latter had to be divided across almost entirely. But it was no great loss to the patient, for the muscular tissue had been almost reduced to a mere membrane. Another feature was that the skin, although it exhibited big bosses, was in many parts extremely thin, and was everywhere entirely separated from the substance of the tumour. So great was the weight of the tumour that on an attempt being made to raise it in the course of the operation, the skin came away bodily, leaving only the nipple. Over the surface were large veins, which gave rise to an apprehension that there would be troublesome bleeding; but, strange to say, in the operation they had only to ligature two little trifling vessels in the lower part of the tumour, which they might almost have let alone. Dr. Purser had made a microscopical examination of the solid masses of the tumour, which proved that they were sarcomatous masses varying in density, being in some places soft and in others dense and fibrous, but in all cases typical spindle-celled sarcoma.

Dr. ROBERT McDONNELL asked, did the cyst contain mucine, and also had any signs displayed themselves of a return of the disease? Some years ago he exhibited to the Pathological Society a tumour similar to this which he removed from a lady in the neighbourhood of Dublin. It weighed 14 lbs., and its history was very similar to that of Dr. Bennett's specimen. It was quite painless, and only gave inconvenience from its bulk. It was very readily removed, and the difficulty of controlling hæmorrhage was very slight. In fact, the skin contracted so rapidly that the pressure on the veins sufficed to control it. The tumour was found to consist of soft spindle-shaped sarcoma, but it was full of mucine. He had seen several similar tumours, though not so large as this, and he had found them all full of mucine. In the case of the lady he had mentioned, the tumour returned in a year, and was successfully removed; but two years later it returned again, and was irremovable, and the patient died.

Dr. BENNETT said the tumour abounded in mucine, as was evident by the threads which could be drawn, and from the surfaces of the sections even after a long immersion in spirit, and when the faces of the sections were laid against each other. The patient ceased to be under his observation a month after the operation, and he had heard nothing but favourable reports since.

TUMOUR REMOVED FROM THE DURA MATER.

Dr. WALTER BEATTY showed a tumour growing from the dura mater covering the upper surface of the right hemisphere and involving a considerable portion of that hemi-

sphere. The specimen was taken from a patient under the care of Dr. Head, in the Adelaide Hospital. The microscopic examination made by Dr. J. H. Scott showed it to be a spindle-celled sarcoma, the cells in fact forming nests. The chief points of interest about the tumour were (1) the fact that there was a depression of bone inwards, causing a depression of the dura mater, and with it the centre of the upper surface of the tumour; and (2) the fact that many years before the patient received a very severe blow from a bottle on the right side of his head, opposite the seat of the tumour, causing temporary unconsciousness. The connection, however, of the growth of the tumour with this injury was not clear.

The PRESIDENT thought the original injury had nothing to do with the growth of the tumour. He was not satisfied that the projection was not the result of fracture of the internal table.

Dr. SWANZY said he examined the patient's eyes, and only found in one eye a slight tendency to optic neuritis.

Dr. BENNETT said, on the question whether the appearances on the inner table of bone were due to fracture, he believed these appearances to be such as to exclude the idea of injury. There was a layer of new bone which possessed none of the characters of the bone displaced.

Dr. BARTON believed there were evidences that the injury was the cause whence the tumour had sprung.

Dr. QUINLAN asked, was the blow of the bottle over the site of the tumour?

Dr. BEATTY: It was stated to be on the right side of the head, and the tumour was on the right side.

Dr. STORY said a respectable percentage of sarcomatous growth in the eyeball was traceable to injuries. Prof. Foulkes, in his work on sarcomatous growth of the choroid, stated that ten per cent. of such cases had histories of antecedent injury. Too much stress, however, ought not to be laid on that, because persons having any wrong with their eyesight had a tendency to attribute it to some external cause.

Dr. HENRY KENNEDY said he had seen disease of the bone exactly similar to this which was traced to syphilitic poisoning. The supposition could scarcely be permitted of a tumour growing for 23 years. He had seen tumours of the kind develop in the brain, but with a vast deal more suffering than occurred in the present case.

Dr. BEATTY, in reply, said he got no syphilitic history in the case. He had no opportunity of examining the spinal cord, but the rest of the brain looked quite normal.

The Section then adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY. MONTHLY MEETING.—FRIDAY, DECEMBER 7TH, 1883.

Dr. THUDICHUM, President, in the Chair.

Dr. DAWSON WILLIAMS read a short paper on certain hygienic considerations with reference to water-closets, observing that a badly-constructed apparatus might itself give rise to obnoxious smells, and even to disease, although the drains and sewers of the house and town were in good order. He illustrated this remark by reference to the ordinary old-fashioned pan-closet, and pointed out, by means of diagrams, the obvious and serious faults in its construction, yet it was a form of closet not only in common use, but one which was constantly being introduced into new houses. What was wanted in a w.c. was as simple an apparatus as possible, which should provide a water-valve allowing the free, easy, and complete passage through it of all matters. The apparatus ought further to keep itself clean, and ought to be as nearly noiseless as possible. The points requiring attention in the selection of a w.c. were—1. That the basin should be of a suitable size and shape—a practical point often neglected. 2. That the trap should be simple. 3. That the water supplied at each delivery should be sufficient in quantity, and have sufficient head to clear the trap—a point only to be ascertained by trial. 4. That there should be as little metal-work as possible, since metal-work necessitated joints, which were very liable to leak, as well as being a corner for dirt. After referring to the clumsy construction of the old leaden D traps, and the manifest advantages of the glazed earthenware syphon traps, Dr. Dawson Williams gave a short description of a form of latrine and of certain automatic flushing cisterns, and con-

cluded by observing that all the various patterns of w.c.'s might be seen in action at the Parkes Museum.

A short discussion followed, in which the President, Dr. Benham, Dr. Alderson, Dr. Campbell-Pope, and Dr. Gower Davies took part.

Dr. J. B. ATKINSON read the following case of

CEREBRAL TUMOUR.

Patient, E. H., *et. 29*, was admitted to Kensington Infirmary on November 10, with the following history:—She had enjoyed good health up to about eighteen months ago; since then she had suffered a great deal from headache, and noticed that her eyeballs were gradually becoming more prominent. Her menses ceased three years ago. No history of sickness, convulsions, or syphilis. Her speech had never been affected. On admission, patient was very apathetic in manner, and still complained of the constant pain on the top of the head. On examination there was no disease of the lungs, heart, &c., and no enlargement of the thyroid body. On December 3 she became much worse, and appeared somewhat collapsed. Temp. 97°. The pains in the head (vertex) then came on in paroxysms, and the patient rapidly sank, became comatose, and died on the 4th. A post-mortem was performed, and a large, soft, lobulated tumour was found at the base of the brain; it filled the sella turcica, and seemed to involve the pituitary body and optic commissure. The growth was somewhat pedunculated, and grew forwards, causing a distinct depression in the right orbital lobe, not involving, however, the brain substance, but seeming to grow down into the fourth ventricle. Microscopically, it showed the structure of a soft glioma.

Dr. J. B. ATKINSON then showed a specimen of a heart with very marked vegetation on the mitral-valve, leading to four large wedge-shaped infarcts on the spleen.

France.

A RETROSPECT OF 1883.

PHYSIOLOGY IN FRANCE.—It will be conceded on all hands that to no kingdom in Europe does the science of Physiology owe so much as to France. The speculative physiology represented so brilliantly at the termination of the last century by Haller was completely eclipsed at the commencement of this century by experimental physiology. The magnificent labours of Xavier Bichat then commenced to sap the foundations of the old edifice, and the splendid achievements of Majendie cast it to the ground. A new path opened, in which Flourens and Claude Bernard resolutely laboured. Experimental physiology is a science of French origin; yet the teaching of physiology in Paris is not quite what it ought to be, owing to the want of sufficient laboratories for the instruction of students. The Professor of Physiology at the Academy of Medicine is a man of clear and methodical mind, and one whose oratorical talents are universally admired, a fact testified to by the large number of students who attend his course, but in his case, as is now so common in Scotland, and especially at the University of Glasgow, he treats each year but a limited portion of the course of physiology, so much so that if a student wishes to have a complete course of physiology, he must attend the Faculty of Medicine for at least seven or eight years. The same thing, again, happens in France as does at the Scotch Boards. At the examination the student is not asked on what portion of the course his studies have been directed under the teacher, but he is unjustly examined on subjects on which he may never have heard a lecture. Subordinate lecturers ought to be appointed; but the remuneration is usually so uncertain that it is difficult to obtain good physiological tutors. It is not a little striking that of the nine chairs of physiology in France, there are four in Paris. We, therefore, agree with the view that these are quite inadequate for such a country as France. The danger to Physiology in France is

due to the bad favour of the Government officials, and surely in what may be termed its parent country, Physiology will not be permitted further to decay without adequate State support.

A VACANT CHAIR AT THE FACULTY OF MEDICINE.—Six months have now elapsed since the lamented death of M. Parrot, and the chair of Diseases of Children which then became vacant continues still unoccupied. This is not a little singular, considering that in Paris there must be many eligible practitioners who have devoted special attention to the subject of this chair, and who would probably willingly accept the position.

FRENCH MEDICAL SOCIETIES.—As usual, many excellent papers were read at the Paris Medical Societies during the year. These have been so numerous that the limits of our space merely permit the enumeration of the most prominent of them. At the Society of Biology, Brown-Séquard continued the demonstration of his experiments on "General Anæsthesia by the Inhalation of Chloroform and Carbonic Acid;" M. Rabuteau communicated investigations on "Thallium," pursuing the demonstration of a law which he some time ago announced, that the poisonous energy of a metal is in a direct ratio to its atomic weight. M. Arsonval read a paper, "On the Influence of Magnetism on Fermentation;" Dr. Sinety communicated a series of researches, "On the Influence of Typhoid Fever on Syphilis and Blenorrhagia." During the course of typhoid he stated that he had seen syphilitic manifestations disappear entirely, and blenorrhagia, on the contrary, to become complicated with cystitis and lymphangitis. Paul Bert brought under the notice of the Society, "The Influence of Refrigeration on the Temperature of the Body;" M. Vigual communicated "On the Development and Growth of Nerves;" M. Burg on "Explanation of Metalloscopic Phenomena;" Brown-Séquard on "Encephalic Hæmorrhages consequent on Lesions of the Cord;" "Anæsthetic Sleep," by Aubert, of Lyons; "Inhibition," by Richet; "Experimental Researches on Malignant Pustules," by MM. Capitan and Charrin; "Microbes in Normal Blood," by M. Ollivier; "Local Physiological Action of Antiseptic Substances," by Laborde, in which he showed that so-called antiseptics cause coagulation of the albuminous substances which bathe the wound, and determine inter-vascular phenomena of a like nature; and that their too strong application may cause gangrene, &c.

At the ACADEMY OF MEDICINE there was read an important paper by M. Nocard, "On Oxygenated Water as a Means of Modifying the Potency of Certain Viruses;" "Diverse Methods of Treating Typhoid Fever," by M. Germain See, on which a long and important discussion followed; "On Purulent Rheumatic Conjunctivitis," by M. Panas; "Prophylaxis of Typhoid Fever," by M. Rochard; "On the Total Extirpation of the Uterus," by M. Demons; "On the Prophylactic Administration of Human Contagious Diseases in Paris," by M. Martin; "The Causes of the Diminution of the Population in France," by M. Decroix, in which tobacco comes in for blame; "On the Influence of Heat on Simple Chancres," by Aubert, &c.

CLINICAL COURSE OF NERVOUS DISEASES AT THE SALPETRIÈRE.—M. Charcot, some of whose signally able and intelligent papers on aphasia have been translated in these columns, commenced his course at the Salpêtrière on Friday, the 30th November. M. Charcot, in opening the course, insisted on the necessity in clinical medicine of descriptions after nature, and in presence of the subject of observation, and entered upon interesting details regarding *ataxia*, recalling especially the hereditary nature of the affection, and

the secondary etiological importance of accidental causes, such as excesses of all kinds, syphilis, traumatism, &c. The lectures will be continued every Friday at 9.30 o'clock. On Mondays the students, at the same hour, will be exercised in examination of patients, under the observation of the Professor.

COURSE OF CUTANEOUS AND SYPHILITIC DISEASES AT ST. LOUIS.—On the same date (Friday, the 30th November) Professor Fournier commenced his clinical lectures at the Hôpital St. Louis in presence of a numerous audience. The course was inaugurated by a lecture on phagedænic gangrene of the genital organs in a healthy young man, who, in the course of twenty-four hours, lost almost the entire skin of the penis and scrotum. The speedy progress of the disease, its spreading nature, and the absence of any known cause, inclined M. Fournier to consider it as due to some septic origin.

OPENING OF THE COURSE OF GENERAL ANATOMY AT THE COLLEGE OF FRANCE—If the experimental is the only method of research, there are two methods of teaching it, viz., the subjective and the objective. The first possesses the great advantage of cleanliness and rapidity. The second only allows the affirmation of a small number of facts repeated at long intervals, in order to allow time for the rejection of preconceived ideas. It is this method which Ranvier, following his illustrious master, Bernard, observes in teaching his class, which meets every Tuesday and Thursday at 4 o'clock. For eight years M. Ranvier has worthily occupied this chair, and his incumbency of it has been characterised by signal progress in the department of histology.

OPENING OF THE COURSE OF CLINICAL OBSTETRICS OF THE FACULTY OF MEDICINE.—Professor Pajot took possession of this chair on the 11th ult., rendered vacant by the death of Professor Depaul. Such is the appreciation in which this *savon* is held that many of the students were unable to find room in the amphitheatre. Among the audience were the following physicians: MM. Tarnier, Tillaux, Gallard, Charpentier, Pinard, &c., and M. Mard. Professor Pajot gave an exposition in clear and eloquent language of his intended course. He commenced by condemning that prejudice, which regards obstetrics as a science little studied, of secondary importance, and of easy comprehension. The field is so vast that one is obliged to lop off several collateral branches, such as embryology, teratology, &c. He insisted on a physiological basis for a correct knowledge of the pregnant condition. He stated that at the present time no one should neglect the antiseptic method in midwifery, it ought to be observed with extreme rigour, and Professor Pajot enlorged M. Tarnier for having been the first to put it in practice at "the Maternity." Professor Pajot in concluding referred to the two excellent adjuncts founded by his predecessor, M. Depaul, viz., the library and museum, which were at the disposal of investigators. The aim which he pursued, he said was scientific and high, that France ought not to be behind other nations in this department, but ought to be able to hold high the obstetric banner.

DR. KOCH'S INVESTIGATIONS INTO THE ORIGIN AND NATURE OF CHOLERA.

In our issue for Oct. 24th, 1883, we gave a translation of Koch's official report to the German Government on the cholera in Egypt. As the epidemic was then subsiding in that country, Koch, with the sanction of his Government, decided to go on to India and continue his investigations. The following is a translation of the main points in his

second report. He says: "I first selected Bombay as the place in India which seemed most adapted for the continuation of the investigations, because numerous cases of cholera had occurred there in August and in the first half of September. But since then the epidemic has rapidly diminished, and appears now to have quite disappeared. According to the judgment of several English officials well acquainted with Indian life, Calcutta was pointed out to me as the town most suitable for the aims of the Commission, because cholera always prevails there more or less. In consequence of these communications I was induced most respectfully to request your Excellency to permit the Commission to go to Calcutta.

"Before, however, the Commission left Egypt I considered it indispensable to examine carefully certain questions, which are most important for the prevention of cholera. The first point was whether the assertion made with great emphasis from several sides be correct, namely, that this year's cholera epidemic in Egypt was not imported from India, but originated in the country itself, and that for the future Egypt must be placed on the same footing as India with regard to the breeding of this dangerous pestilence. In order to form an opinion on this point, the Commission went on the 6th of October from Alexandria to Damietta, where the epidemic commenced, and there made most careful investigation for several days into the origin of the plague. I reserve my detailed report on the results thus obtained.

"Those questions about the efficiency of quarantine and the importation of cholera by pilgrims going to and from Mecca were of still greater importance. With these points, too, the Commission occupied itself during its stay in Alexandria, and carefully inspected the arrangements and management of the quarantine establishments at Gabari and Mels, near Alexandria, and of the establishment lying at the mouth of the eastern arm of the Nile at Damietta. When, however, the last outbreak of cholera amongst the pilgrims at Mecca was reported, and it was determined that the pilgrims coming from Djeddah were to be kept in quarantine at Tor, so favourable an opportunity was offered of obtaining information about these important matters that I felt myself bound not to let the occasion pass. But, as there is no regular communication with the Egyptian places of quarantine on the Red Sea, there was nothing to be done but to claim the assistance of the Egyptian Government to enable the Commission to visit the quarantine ports. The Commission proceeded to Suez from Cairo on the 30th of October; on the 31st it proceeded to Tor, paying another visit there, and finally inspected the quarantine hospital at the Springs of Moses, near Suez.

"This expedition was most instructive. We had the opportunity of seeing on the first visit to Tor the quarantine camp, which was fitted up for the reception of the pilgrims, but not yet occupied. The same day one of the Austrian Lloyd steamers, with nearly 500 pilgrims on board, entered the port of Tor. According to the statement of the ship's doctor, all were well on board. But during the disembarkation of the pilgrims and their conveyance to the camp, both of which took place in the presence of the Commission, some of the pilgrims appeared very ill, and were suspected of cholera, so that they had to be sent to the quarantine hospital. At our second visit to Tor we found that another ship had arrived with pilgrims, who had already landed. Meanwhile, cholera had broken out in both camps; there were three deaths from cholera among the pilgrims of the first ship, and one amongst those of the second ship, and a corresponding number of cases of illness. Whilst the Commission was present in the hospital one cholera corpse and several patients with characteristic symptoms of cholera were observed. In general the Commission exerted itself while inspecting the quarantine establishments at El Wedj, Tor, at the Springs of Moses, and the Sanitary Institution at Suez, to obtain as deep an insight as possible into the conditions of the importation of cholera into Europe, and hopes, both from its own investigations and from the information received from the officials and pilgrims, to be shortly in a position to deliver a trustworthy opinion on the subject.

"Besides these investigations the Commission inquired into various subsidiary questions connected with the epidemic—such as the supply of and filtering of water, the influence of the rise and fall of the Nile on the course of the epidemic, the mode of burial, infection of the ground by urinals, meteorological influences, &c. Several more dissections were

made at Alexandria, and valuable observations collected on dysentery and the occurrence of tubercles, and further about certain parasites which exist in the pyloric artery, and are often found in corpses in Egypt."

WEDNESDAY, JANUARY 2, 1884.

CATHETER FEVER.

NOTHING tends so much to demonstrate the progress that is being daily made in our knowledge concerning the causation and pathology of disease, as the frequency of such discussions as that which took place at the meeting of the Medical Society of London on the 17th ult. Prior to that time it might, with some appearance of justice, have been affirmed that the question of fever resulting in patients subjected to catheterisation was at least fairly well understood; and that the explanation which ascribed it either to toxæmic symptoms or to irritative lesions was in unison with experience. It is always a difficult matter for the surgeon whose whole life is a practical acquaintance with clinical facts, to import into his consideration what is for him a theoretical ground of belief, especially when he is unable to follow out the proof of it *post mortem* in the body of his patient. Ordinarily, when dealing with examples of fever occurring in patients who have entered on a "catheter life," he can picture with more or less completeness and accuracy the exact conditions existing in the organs at fault, and can associate them with lesions of defined extent and of appreciable importance. When, however,

he is further called upon to admit the presence of unmistakable fever, even though it be denominated a "low" or "irritative" fever, or called by any other distinctive appellation; that in progress and results it may have characteristics in common with the form of fever well understood and well known to go along with particular structural defects, while, at the same time, no one of these distinctive lesions co-exists with it; then the faith of the surgeon is taxed beyond its strength, and rather than accept what is, in the present state of knowledge, almost impossible to recognise, he prefers to adopt other mode of explanation more in consonance with his own practical experience.

Such a condition of doubt has now been awakened by the able address on "Catheter Fever" delivered by Sir Andrew Clark on December 17th at the Medical Society; and such difficulty in approving his conclusions has arisen as is referred to in the preceding paragraph. Premising that it was not his purpose to ask for attention to the surgical state known under the title of urinary fever, uræmic fever, or other familiar name by surgeons, Sir Andrew proceeded to describe what he wished to convey by the term catheter fever; and, among other propositions for discussion, enunciated the following distinctive features of the disease: "This fever is neither distinctly uræmic nor distinctly pyæmic. Although having some of the characters of each, it has all the necessary characters of neither; probably it begins in the nervous system; probably the disturbance of the nervous system reacts in the first instance upon the general metabolism of the body, and in the second instance upon the secretory organs, beginning with the kidney; the effect upon the kidney may consist either in structural alterations in the kidney, invisible by the aid of our finest instruments of research, or (as seems to me much more probable) in alterations of the constitution of the blood, that dynamic condition of its constituents in the renal vessels essential to the elaborative action of the secretory cells there; and lastly, that the occurrence of these conditions may be, and often is, enforced by septic reabsorption into the blood." Unless carefully studied and thought out, this statement will probably not convey much information to the mind; but when once thoroughly understood, it will be found to contain two salient factors of belief—(1) that catheterism may influence the nervous system—in the way of shock, if such a supposition is preferred—in a certain number of cases, in such fashion as to lead to the production of (2) an obscure and even dangerous form of constitutional disturbance, of a feverish nature, and under the influence of which the nutritional exchanges of the body are imperfectly or abnormally fulfilled. The acceptance of this proposition makes a necessary demand on the faith of everyone who has not himself enjoyed opportunity of observing, or is not endowed with capacity for observing, the special series of events which make up the clinical picture of a case such as Sir Andrew Clark has described. For these the attitude of unbelief presents attractions greater than one of adhesion to a view that has more of difficulty surrounding it than that which enables the sequence of cause and effect to be rapidly imagined, in agreement with well-recognised and frequent instances of direct connection between local structural

mischievous and constitutional affection. The whole discussion that followed the reading of the paper went to demonstrate the truth of this observation; and it leaves the impression that Sir Andrew Clark is entitled to declare, as he did declare, that notwithstanding all the criticism he secured, he is still as little really understood as at the time when he first propounded the question for consideration.

In explanation of the symptoms exhibited by such patients as were taken to be examples of the form of catheter fever under consideration, Sir Henry Thompson insists that its appearance in elderly men is sequential to long-standing urethral obstruction, and then it co-exists with advanced renal disease in all cases, and the conclusion he arrives at is, "that it is not an attack of any catheter fever, but the want of the catheter at an earlier stage of the malady, which has placed these individuals in a dangerous condition . . . and that the only association the word has with this fever is the important fact that the catheter was wanted and not used." In this way, however, Sir Henry Thompson approaches to agreement with Sir Andrew Clark, inasmuch as he admits the pre-existence of some such condition as the latter has well described under the term "renal inadequacy;" how produced does not for the moment matter. In a state of nutritional degeneracy so induced the introduction of a catheter is followed by "catheter fever;" and while Sir Henry insists that gross changes in the urinary organs are answerable for the result, Sir Andrew contends that the nervous system being directly and immediately affected, reacts on the constitutional state, and so leads to structural kidney changes of a kind inappreciable by our present instruments of examination. In a sense each meets the other; but also, neither fully occupies the ground the other assumes, for Sir Henry Thompson so classifies the cases he deals with as to exclude consideration of those to which Sir Andrew Clark most especially alludes, and which want all those evidences of pathological change that are a primary factor of his opponent's description.

More in accordance with the views of Sir Andrew are those expressed in a clinical lecture by Mr. A. T. Norton, entitled "What is that Condition which has been called Urethral Fever?" (printed in the *Lancet* of April 29th, 1882). Mr. Norton, after describing cases in which passing a catheter was followed immediately by paralysis of parts of the sympathetic nerve, branches of the cerebro-spinal nerves, hemiplegia, herpes due to nerve irritation, albuminuria, &c., concludes that so-called urethral fever is a reflex paralysis, or, in other words, it is an exciting impression upon, or injury to, a set of peripheral nerves, which, by reflexion through a centre, may result in paralysis of the whole or part of the united cerebro-spinal and sympathetic nervous systems, either transient in character, or ultimately through the vaso-motor system, bringing about structural change, or even suppuration, in organs or other tissues.

However devoid of direct bearing on the paper which excited it, the discussion must rank among the most important that have taken place of late; whether regarded for the excellence of the speeches made during it, or for the authoritative position enjoyed by most of the

speakers. Mr. Savory incidentally gave utterance to a truth that deserves most careful recollection, viz., that the amount of urea excreted, rather than any other character of a suspected urine, should be taken as the criterion of the efficiency of the renal organ. Mr. Savory further gave the weight of his high opinion in support of the contention of Sir Andrew Clark to the effect that it is not only by pathological changes that alterations in the kidney can be assumed to exist. Mr. Savory also is certain that in many cases where fatal results ensue after catheterism, the kidneys are seriously affected, although not in ways corresponding with descriptions given in books on kidney diseases; they are not characterised after death by any very striking changes. On the principal point at issue, the cause of the condition to which Sir Andrew Clark has drawn attention, Mr. Savory registers the opinion that it is due to constitutional disturbance produced through the nervous system; and in this he practically arranges himself side by side with him. The subject, however, as Sir Andrew has declared, is not yet exhausted; and it must be reconsidered with, as he suggests, a closer regard to the ground laid open for discussion.

THE IRISH CONJOINT EXAMINATION SCHEME.

We publish to-day a letter by Dr. Barton in defence of the proposition that the Irish Colleges shall surrender their separate licensing powers and bind themselves to a diploma-granting coalition, which proposal we criticised from its most important aspects in our issue of December 19.

Dr. Barton has not succeeded in convincing us that the scheme would serve any good public purpose, and if he did, we doubt that he would succeed in the attempt to satisfy the Fellows of the College of Surgeons as to the expediency of sacrificing £1,000 to £2,000 a year of the collegiate income in order to carry out the sentimental idea of a symmetrical Irish licence in medicine, surgery, and midwifery.

Now, as to the propriety of insisting that the practitioner shall be properly tested and qualified in these branches of knowledge, we are entirely in accord with Dr. Barton and with the recommendations of the Royal Commission, though we are somewhat surprised to find the opinions of that Commission in such unexpected favour with those who repudiated them this time last year; but we do not believe that any voluntary coalition of licensing bodies can afford sufficient guarantee that the practitioner has been effectually tested or is competent for his work.

We know to how low a grade conjoint examination can descend by our experience of it elsewhere, and we see not the least reason to suppose that those monetary and teaching interests which degraded it in Scotland will not produce the same effect in Ireland. We therefore insist that this proposed Irish conjunction would not in the least degree serve the purpose, i.e., to erect a minimum competency standard of education, at which the Medical Reform Bill aims, and that it therefore could not, and ought not, in any way to supersede the

necessity for a compulsory conjunction between all the licensing bodies in each kingdom, supervised and guaranteed by a vigilance committee independent, it is to be hoped, of monetary influences.

To obtain such tribunal of competency as this we would be content that the Irish Colleges should sink their power of separate licensing, being satisfied that they would be more than recouped for the concession by material advantages arising from the transaction; but we altogether object to the proposition that they should voluntarily surrender their individuality without thereby improving education, counteracting downward competition, or serving any other useful public purpose. If the proposed conjunction does not effect these purposes we can hardly suppose that Dr. Barton is serious in his statement that a patched-up coalition between the two Colleges, in which the three other Irish licensing bodies are not participants, would "remove the only good reason which can be advanced for depriving them of their old-established privilege of conferring a registrable title."

Dr. Barton goes on to say that "there is a *certainty* of the Colleges being in a very much better position (by reason of this conjunction) for seeking an important modification of the new Bill; and there is another *certainty* that if the Government do not see fit to agree to the change the opposition to the Bill will be made on such fair and just grounds that it will command support from all sides."

So far from agreeing in this statement, we are emphatically of opinion that the present movement will seriously prejudice the chance of the Colleges' obtaining amendments to the Bill. It will exhibit them to Government and Parliament as a couple of institutions which, having made money as long as they could by the sale of diplomas which they now admit to be only half qualifications, now seek to save for themselves the power to carry on the same lucrative trade regardless of the public welfare. In our opinion, the "*certainty*" is that such an attitude would at once put the Colleges outside the pale of negotiation, and ensure that the Bill—if passed at all—would be passed in spite of them and without regard to their interests.

But Dr. Barton's letter contains fallacies as to the effect of this scheme on the collegiate finances which cannot be allowed to pass as truths. We have already asserted—and we believe the statement cannot be disputed—that the Irish College of Surgeons stands to lose at least £1,000 a year, and possibly much more, by this bargain. Dr. Barton considers that our arguments on this point "cannot be satisfactory to anyone who knows what an attraction a full qualification for one examination is to students." We are, in fact, invited to assume that the conjoint examination will bring new candidates to the Colleges in sufficient numbers to recoup them for this assured loss. We, however, do not believe that it will bring half-a-dozen extra candidates, and we should have supposed that Dr. Barton, who knows so well the causes which have alienated Irish students from the Colleges, would have seen that his hopes are illusory. Every teacher in Dublin knows

right well—and it has been proved beyond all possibility of doubt by the statistics quoted in the Commissioners' report—that Irish students go to Glasgow and Edinburgh *not* to seek a conjoint diploma, *not* to escape diploma fees, *not* for ease of examination, but because they can pass there on a year's less study than in Dublin.

Nominally four years of study are required throughout the kingdom, but, as a matter of fact, a student who has completed the entire curriculum necessary for the Scotch double diploma is still some courses short of the Dublin requisites, and if he wants a Dublin diploma he must spend a winter in making up these deficiencies. This it is which sends the Irish student out of his own country; but the Dublin teachers have been slow to recognise the fact because it would have pointed to the necessity for cutting down lecture-courses.

Until the Dublin course is brought to the Scottish level students will emigrate, no matter what other blandishments may be lavished on them by the promoters of the conjoint scheme, and we therefore do not believe that any coalition will attract any considerable number of applicants so long as a year's difference in the period of study exists.

When Dr. Barton writes that under the Medical Bill "the entire income of the College which it now derives from its qualifying title must cease," we are compelled to charge him with unacquaintance with the provisions of the Bill. He ought to know that the Bill gives to the Colleges the right of continuing the three primary professional examinations, and allows them to charge what fees they please; and that it also gives them their equitable share of the final diploma fee after the examiners have been paid. All, in fact, that the Colleges would lose under the Bill would be the right to grant separate licences for registration, and the promoters of the conjoint scheme do not seem to estimate this privilege very highly, seeing that they propose to surrender it at will in the flurry of apprehension at the coming reforms.

Notes on Current Topics.

The Health of Newcastle-on-Tyne.

THE excessive death-rate of Newcastle-on-Tyne has for some time past been a subject of much anxiety to those who are entrusted with the sanitary administration of the city; and the medical officer of health, Mr. Henry Armstrong, has drawn up an able and exhaustive report in this connection, and which was published on Friday last. The diseases principally influencing the high mortality have been measles, affections of the respiratory organs, and kidney complaints, a large percentage, however, being attributable to scrofula, tabes, and other wasting diseases, and premature births. Taken on the aggregate, the death-rate for 1883 in Newcastle has reached a figure *thirty per cent.* higher than that registered in the year immediately preceding, and even that was not a low one. It is important to note that the mortality arising from nephritis and other renal affections has been *two hundred and six per cent.* higher this year than last, and the

explanation given is that the result is due to the effects remaining over from precedent epidemics of scarlet fever. The ultimate cause leading to this disastrous result, however, is not, in our opinion, suggested by Mr. Armstrong's report, inasmuch as he is singularly silent respecting the influence of the Newcastle water supply in determining the health of the city. This is far from being satisfactory. It is of such a nature that, in periods of greatest danger from infection, the regular supply of water for domestic use is supplemented by means of fluid pumped from the River Tyne at a point a few miles above the city, but below where the sewage not only of several considerable villages, but also of the town of Hexham, is poured into the river. Moreover, the supplemental water is withdrawn at a time when, through drought, the natural level is at its lowest, and therefore more sewage-laden than in the intervals of rainfall. That fever may be, and often is, conveyed into large towns by "drinking" water drawn from sources that should never be permitted to afford such a supply is a most obvious truth in sanitation; and the history of epidemic fever along the Tyne Valley, taken together with the information supplied by Mr. Armstrong as to renal disease sequential to scarlatina, irresistibly suggest a relation between cause and effect that will demand the careful attention of whosoever essays the purification of Newcastle. We have on previous occasions referred to the great improvements effected in Newcastle within the past few years, and this latest report of the city's medical officer indicates the activity that is still being exhibited in the same direction, while it also gives promise of yet more complete measures in the future. We have referred to it now for the two reasons—(1) That it is an important and ably-drawn document on a subject of the first importance in itself, and (2) that it is marked by the omission to which we have referred, and which, to the eye of an observant visitor to Newcastle, deals with one of the worst errors connected with the sanitary administration of the flourishing metropolis of the Tyne.

The Case of Messrs. Bower and Keates.

THE sympathy shown towards Messrs. Bower and Keates by the profession is taking a very practical and satisfactory shape, and may be accepted as indication of a determination to protect such medical men as may become subjects of vexatious prosecution in the discharge of their professional duties. Not only has a very respectable list of subscriptions to the defence fund already been announced, but the two Royal Colleges of London have each passed resolutions condemnatory of the persecution endured by Messrs. Bower and Keates, and approving the proposal to lend them official aid under the circumstances in which they have been placed. In connection with the meeting held for this purpose at the Royal College of Surgeons of England, we are requested to state that the absence of the name of the President of the Royal College of Surgeons from the committee appointed to carry out the measures deemed fit in regard to the case of Messrs. Bower and Keates is due entirely to his not having been made aware of the intention to hold a meeting upon the subject. Hence he, as President of the College, has been unable to add the sanction of his authority to a movement which has his entire sympathy and approval.

The late Mr. James Shuter.

THE friends of the late Mr. James Shuter, F.R.C.S., whose death caused so great a feeling of regret in the profession, have decided to raise some suitable memorial of the deceased surgeon. The movement has originated amongst some of Mr. Shuter's friends and colleagues at St. Bartholomew's Hospital, and these now invite subscriptions towards it from past and present students of the School, and from others who may exhibit interest in the success of the scheme. The office of treasurer to the fund about to be raised has been accepted by Dr. Robert Martin and Mr. Luther Holden (at present absent from England); and the honorary secretaries—to whom cheques, &c., payable to the Shuter Memorial Fund, and crossed Coutts & Co., should be sent—are Messrs. Bruce Clarke, F.R.C.S., 46 Harley Street, W.; and A. Clune Fletcher, 12A Charterhouse Square, E.C.

The Coombe Lying-in Hospital.

ON Thursday week the election of a Master for this institution, *vice* Dr. Kidd, whose term of office has expired, was held. Fourteen Guardians and Governors attended, and there were three candidates—Dr. Mason, junr., Dr. Neville, and Dr. William Roe—all ex-assistants of the hospital. The Right Hon. the Lord Mayor occupied the chair; but as the charter gives the chairman a vote only in case of a tie, his Lordship's functions were confined to declaring the result. The electors on the first round voted for two candidates out of three, each elector being at liberty to send in one or two names, as seemed to him best. The result was—for Dr. Mason, 12; for Dr. Neville, 7; and for Dr. Roe, 3. A vote was then taken between Drs. Mason and Neville, with the result that the former received 9 votes to the latter's 4. Dr. Mason's appointment will give general satisfaction, but it is simply fair to add that the two other candidates were excellent. One only, however, can win in such a contest.

Small-pox v. Pemphigus.

THE *Blomfontein Gazette* of Nov. 22 last contains a letter from one who signs himself "M.D.," and from which it appears that much confusion has been created at Kimberley by failure on the part of medical men there to distinguish between the eruption of small-pox and that of pemphigus. It is a little curious to read the suggestion gravely made in the letter to the effect that the professional aspects of the whole affair should be carefully drawn up by some disinterested medical man, giving both sides clearly and distinctly, and that this draft should be signed by all of the medical gentlemen who have given opinions either one way or the other, then duly forwarded to some authority able to give an opinion or decision. Such a step would, M.D. believes, be advantageous to themselves and to their professional brethren in South Africa who may be similarly placed as themselves; and he further suggests than any experiments—such as inoculation of the contents of the bullæ—and results should be forwarded; also a description of the present epidemic cutaneous disease amongst the Kafirs, which, as far as his experience goes, partakes of two characters—viz., *pemphigus acutus* or *vulgaris*, and *frambesia*.

The matter is certainly an interesting one, and we shall wait with some curiosity to see how far M.D.'s recommendations are followed.

Fatal Explosion of a Mixture.

At Manchester an inquest was lately held relative to the death of one Turley, a shingler. It appeared that deceased went to the shop of a pharmaceutical chemist for three pennyworth of quicksilver and three pennyworth of aquafortis. He had been in the habit of purchasing similar quantities in order to mix them into a kind of ointment. Both articles were placed in the same bottle. Deceased then placed the bottle in his breast pocket and left the shop, but shortly afterwards the stuff exploded and the contents of the bottle burnt the face and eyes of the poor fellow so seriously that he died at the Manchester Eye Hospital. In his voluntary statement, the chemist said that he had never known the mixture to explode before, though he had always served deceased with the articles separately, generally placing the quicksilver in a pill box. He should not have mixed the two, but deceased, after being served with the quicksilver, pushed the bottle towards him, and said "Give me three pennyworth of aquafortis." The inquest was adjourned, it being probable that a verdict of manslaughter against the chemist would be returned.

The Autopsy of Marion Sims.

THE New York *Medical Record* publishes the result of a post-mortem examination made to investigate the cause of death of this distinguished obstetrician. "The heart (it says) was enlarged with adherent pericardium. The valves were competent. The calibre of each coronary artery was markedly narrowed by atheroma, which was partly calcareous. In the muscular septum, at the upper part of the interventricular septum, there was a patch of fibrous myocarditis as large as a silver quarter of a dollar with the beginning of an aneurismal pouch. There was a similar fibrous myocarditis in the papillary muscle which controlled the anterior segment of the mitral valve. Both ventricles were dilated and the left hypertrophied. The lungs were slightly congested and oedematous. The parietal and visceral pleura were everywhere adherent. The kidneys and liver showed lesions of chronic congestion."

A MEETING of the Fellows of the Royal College of Surgeons in Ireland will be held on Thursday, the 3rd of January, at four o'clock p.m., to witness the election of a Professor of Dental Surgery. It is understood that Dr. Theodore Stack, of the Dental Hospital in York Street, Dublin, will probably be chosen.

DR. MOSES GRIFFITHS, D.L., and J.P. for the County of Pembroke, aged 95, died at his residence on the 29th Nov. He served in the Peninsula as army surgeon from January 7, 1810, to the end of the war, including the battles of Busaco, Fuentes d'Onoro, Liege, and assault of Ciudad Rodrigo, siege of Badajos, battles of Salamanca, Vittoria, Pyrenees, Nivelle, Nive, Orthes, and Toulouse. He was wounded at the affair of Vich-Bigone, served in India, Arabia, and the Burmese Empire from May, 1818,

Death of Professor Reichert.

LAST week, in our Retrospect of 1883, we mentioned that Professor Waldeyer, of Strassburg, had been called to Berlin to undertake part of the work hitherto under the care of the esteemed Professor Dr. Karl Boguslav Reichert, and this week we have to announce the death of the latter gentleman at the age of seventy-two. Reichert was a distinguished pupil of Johannes Müller, and on the death of this eminent anatomist he was removed from Breslau to the post he held up to the time of his death, this event taking place on December 21st last. He was Professor of Anatomy and Physiology, Director of the Berlin Anatomical Institute, and Member of the Academy of Sciences. His death will render necessary further changes, as it is now well recognised that the duties undertaken by him for so many years are too onerous for any one individual to perform with satisfaction to all parties.

An Impostor.

THE profession is so frequently subject to imposition and fraud that its organs do well to expose cases as they occur as cautions to the victimised and those who perpetrate the acts. On Friday last a man, who refused his name and address, was sentenced to three months' imprisonment at Leamington for a series of frauds upon medical men in Warwickshire. He represented that his name was John Murray Gibbs, brother of Dr. Heneage Gibbs, with whom he was upon unfriendly terms, and that he had returned, weakened by rheumatic fever, and with five motherless children, from New Zealand, where he had lost both his wife and practice, obtaining thereby various sums of money.

It may be as well also to mention here that another individual, a passed member of the profession, though fortunately not now on the Register, is soliciting assistance to convey him to the Colonies, in order to commence life afresh. This person has been thus engaged for some years, and seems to make it pay, as he is as far from the Colonies now as ever, and smelled as strongly of alcohol as usual, when we recently came across him.

WE have satisfaction in recording that Mr. Orolly, of Dublin, whose alarming illness from typhoid fever we recently recorded, is entirely recovered, and has resumed his practice.

WE are asked to mention that Dr. Louis Parkes, who has just gained the certificate of Sanitary Science at the University of London, was a student in Dr. Corfield's hygienic class and laboratory at University College, London.

THE baronetcy recently announced in our columns as about to be conferred upon Professor Lister was officially gazetted on Friday last. It affords us unqualified pleasure to offer in the name of the profession our New Year's congratulations to Sir Joseph, and to express the hope that he may have many years of health to enjoy the honour so well deserved.

Jervis Street Hospital, Dublin.

THE election for the post of Surgeon to this hospital, in the room of Dr. James Edward Kelly, who had relinquished the intention of returning from San Francisco and resuming his practice, took place on Friday last, the candidates being Dr. Gunn and Dr. Gogarty, and the result of the voting was that Dr. Gunn scored 71 votes against Dr. Gogarty's 50, and was, thereupon, elected. Dr. Clancey, who was spoken of as a candidate, did not offer himself. Rumour says that money changed hands in connection with the election, a considerable sum going to the outgoing surgeon, and a further sum accruing to the hospital funds by the "making" of governors at 20 guineas apiece, who were expected to vote for one or other candidate. If this be true, we are gratified to observe that the competition was reasonably close, for the event will go some way to prove to future purchasers of hospital appointments that the payment does not necessarily secure them from a hot contest, and possibly from defeat. We hail the transaction as one more proof that the system of buying the charge of the sick in Dublin hospitals is coming to an end.

THE Lettsomian Lectures of the Medical Society of London, session 1883-84, will be delivered by R. Brudenell Carter, F.R.C.S., Ophthalmic Surgeon to St. George's Hospital, on January 7th and 21st, and February 4th, 1884, at 8.30 p.m. Subject—"Modern Operations for Cataract."

WE are asked to announce that Mr. H. H. Johnston will give a discourse on "Kilima-Njaro, the Snow-clad Mountain of Equatorial Africa," on Friday evening, January 25, at the Royal Institution. Professor Bonney's discourse on "The Building of the Alps," announced for that evening, will be given on April 4.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From measles, 4.7 in Brighton, 2.7 in Salford, 2.6 in Manchester, and 2.4 both in Derby and Birkenhead; from scarlet fever, 3.6 in Leeds, and 3.1 in Newcastle-upon-Tyne; from whooping-cough, 1.8 in Huddersfield, and 1.4 in Sheffield; and from "fever," 2.6 in Preston and 1.9 in Blackburn. The 39 deaths from diphtheria included 19 in London, 6 in Glasgow, 3 in Hull, and 2 in Dublin and Birmingham. Small-pox caused 4 deaths in Birmingham, 2 in London, 2 in Sunderland, and 1 in Glasgow.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

A NOVEL THEORY OF VOICE TRAINING.—Dr. Carter Moffat delivered a lecture in the Christian Institute, Glasgow, on Friday last, to a large audience, mainly composed of professional men and musical critics, on voice training by chemical means. Dr. Moffat maintained that the presence of peroxide of hydrogen in the air and dew of Italy had some connection with the beauty of the Italian vocal tone. A series of illustrations by people taken from the audience, who inhaled a chemical compound made to represent Italian air,

were largely satisfactory—a full, clear, rich, mellow tone being produced by one application. Several gentlemen present gave their favourable opinion of the new idea. Dr. Moffat's own illustrations were quite unique. Taking what was originally a voice of power and resonance but destitute of intonation, he showed by chemical means this could become a tenor of great range. Some twenty notes, ranging from the lower to the higher register, were sung without any effort by the possessor of a voice of this character.

THE FELLOWSHIP OF THE EDINBURGH COLLEGE OF SURGEONS.—At the last meeting of the College the following gentlemen were elected Fellows:—James M'Connochie, L.F.P. and S. Glasg. (1865), M.D. Glasg. (1872), Glasgow; James Stevenson Forrester, L.R.C.P. and S. Ed. (1873), Chatham; Archibald Somerville, M.D. and L.R.C.P. and S. Ed. (1873), Leek, Staffordshire; William Gillespie, L.R.C.S. (1878), and L.R.C.P. Ed. (1882), Methven, Perthshire; James W. B. Hodsdon, L.R.C.P. and S. Ed. (1880), M.D. and C.M. Q. Univ. Irel. (1881), Edinburgh; Alexander Stewart Brown, M.R.C.S. Eng. (1878), London; James Dewar, L.F.P. and S. Glasg. (1869), Buxton; Robert Torrance, L.R.C.P.E. (1870), L.R.C.S.E. (1874), Newcastle-upon-Tyne; John Macdonald Brown, M.B., C.M., Ed. (1880), F.R.C.S. Eng., Edinburgh.

INTERESTING TO DENTISTS.—While a servant girl in Thurso was cleaning a fish on Friday, the 21st ult., she found in its stomach a complete set of false teeth.

EDINBURGH PROVIDENT DISPENSARY.—The annual meeting of the subscribers to this institution was held last Thursday, under the presidency of Dr. Teape. An abstract of the treasurer's account showed that the income during the year amounted to £105 3s. 1½d., and the expenditure to £93 7s. 1½d., showing a gain of £12 16s. on the year. As, however, the account was begun with an unfavourable balance of £41 9s. 6d., there is still a balance due to the treasurer amounting to £28 13s. 6d. The Ladies' Acting Committee reported that they had attended to upwards of thirty urgent cases brought under their notice by the medical officers and nurses, and had afforded much-needed relief in the way of clothing, provisions, &c. In moving the adoption of the report, the Chairman remarked on the good work the dispensary was doing, and laid special emphasis on the fact, brought out in the report, that there had only been two fatal midwifery cases out of the 1,500 attended. Another commendable feature in the working of the institution was that no expense was incurred on account of management—a fact which brought out the self-sacrifice of those who conducted and directed the affairs of the Dispensary.

"THE HISTORY OF THE UNIVERSITY OF EDINBURGH."—The promised History of the University, by the Principal, Sir Alexander Grant, has made its appearance in the form of two bulky octavo volumes. The work will doubtless find a place on the shelves of all graduates of the University. We hope to be able to give at some future date a detailed account of its contents.

ST. ANDREWS UNIVERSITY ASSESSORSHIP.—The election of an Assessor to the Council of St. Andrews University has resulted in the return of the Hon. Richard Cross, M.P.; by a majority of 386 votes. The candidates nominated at the meeting of the General Council were Dr. Cleghorn, of Strathvilly, Fife, and Dr. Richardson, F.R.S., of London, the late Assessor, and a strong desire was expressed by several of the members present that, as Dr. Richardson had held the office for three terms, his supporters should not press his candidature on this occasion, but should allow Dr. Cleghorn to be

unanimously elected. This suggestion being declined, Dr. Cleghorn retired, and Sir Richard Cross was nominated in opposition. The supporters of the latter calculated that the medical vote, which predominates in the constituency, would, as on previous occasions, go largely in favour of Dr. Richardson. Sir Richard's committee, however, turned the election into a political contest, and so divided the medical vote. The total available vote is 1,462, and 1,095 voted. The voting was by means of voting papers, the electors being resident in all parts of the three kingdoms. The polling closed on Friday night, and the enumeration of the votes took place on Saturday. The result was—For Sir Richard Cross, 727; for Dr. B. W. Richardson, 341. There were seven spoiled papers. At the last election in 1879, Dr. Richardson received 541 votes, and Dr. Carpenter, who was put up against him, 480.

Correspondence.

THE CONJOINT EXAMINATION SCHEME.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—An article in your issue of December 19th discusses the action now being taken by the Council of the Royal College of Surgeons of Ireland with the College of Physicians to form a combined court of examiners, in order that students may obtain a full qualification in medicine, surgery, and midwifery through one examination. The view taken in that article seems to me one-sided, and calculated to prejudice unfairly the minds of the Fellows of the Colleges. *Audi alteram partem* is a sound maxim before we make up our minds on any vexed question; so I appeal to you to permit the Fellows to hear through your columns what appears to me—and I may add to a large majority of the Council of the College of Surgeons—the true state of the case.

The Royal College of Surgeons in Ireland has for years been raising the standard of examination for its Letters-Testimonial (as its qualifying title is called), and I believe it may be favourably compared with that of any surgical licence in the world; but it remains, and must remain, what the Royal Commission has called a "half qualification," the existence of which has been held as a main reason for legislation (see clause 7, Report of Royal Commission).

In the Bill which nearly became law last session it was a fundamental principle that no name should be placed on the Register unless the owner thereof was qualified in medicine, surgery, and midwifery—in fact, the complete removal of all half-qualifications. The soundness and justice of this none could dispute, but the means by which the late Bill accomplished this left the Colleges without either work to do or means to support them. That Bill failed to pass, and the new Bill has not yet seen the light. An opportunity is therefore now afforded the Colleges to remove the only good reason which can be advanced for depriving them of their old-established privilege of conferring a registrable title, and this they can do by combining, and thus conferring a complete qualification in medicine, surgery, and midwifery, which combination is provided for and encouraged by the Medical Act of 1858.

The various objections which the opponents of this union of the Colleges allege against it may be thus classed:—1st. Financial. It is said to mean a loss to the College of Surgeons of over £1,000 a year. The grounds upon which this statement is made are perhaps satisfactory to the writer in the *Medical Press*, but cannot be to any one who knows what an attraction a full qualification for one examination is to students, and who, calculating upon what appears to them reasonable data, make out no loss at all; but be this as it may, one thing is certain, that the entire income of the College, which it now derives from its qualifying title, must cease as soon as any Bill passes containing the provisions of the late Bill. Contending, therefore, about problematical loss of this kind, in face of a certain cessation of income, is childish.

2. The *Press* approves of combination, but it must be voluntary—that is, the student must be free to choose whether he will have the half qualification or the complete

one—in other words, the entire strength and use of the combination is to be laid aside, and no real or honest endeavour made to meet the reasonable demands of the Government.

3rd. After all, our opponents say, you have no certainty that you will obtain a modification of the Bill by this voluntary surrender of your power of single qualification; and we reply—true, but there is a *certainty* of the Colleges being in a very much better position for seeking an important modification in the new Bill, should it be the same as that of last session, and there is another *certainty*, that, should the Government not see fit in the first instance to agree to the change we ask for, our opposition to the Bill will then be made upon such fair and just grounds that it will command support from all sides, and procure during the course of the Bill through Parliament the modifications we demand.

We do not desire to obstruct medical reform, but we desire to meet the reasonable demands of the Government, and thus make it unnecessary to deprive our Colleges of their *chartered rights*, and this, by making a combination which even the *Medical Press* admits is most desirable in the interest of the student and of the profession.

I remain, Sir, yours, &c.,

JOHN KELLOCK BARTON,
Past President, Royal College of Surgeons, Ireland.

THE ROYAL UNIVERSITY OF IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The third resolution to which I wished the attention of Convocation to be directed at the autumn meeting is, "That the Senate be requested to admit undergraduates of the late Queen's University in the Faculty of Medicine to two examinations in the year." In discussing the second resolution, I endeavoured to show that *one* examination in the year was not sufficient to enable the University to attain the objects which called for its creation. I propose in the present letter to point out how the students of the late Queen's University are thus seriously hampered in the pursuit of their medical curriculum.

The Queen's regulations, under which these students entered, provided for *two* examinations in the year, and required the fees for degrees to be paid only on the *first* occasion; if a student were unsuccessful he might present himself at subsequent examinations without paying again. The Senate of the Royal has thought it right to prevent such students presenting themselves for examination a second time in the same year, and insist on their paying fees at *every* examination.

Now, Sir, I believe the Senate has the legal power to do this, but I think few will consider it equitable. The Queen's students have fulfilled their part of the contract, and the Royal may very reasonably be asked to perform the other part, which would have been done by the Queen's University if it still existed. I hold and believe that there is an *essential* difference with regard to the examination fees paid to the two Universities. The Queen's charged for the degree, and the Royal charges for the examination. Surely, then, it is not right for the Royal to accept the Queen's fees from Queen's University students and make them pay over and over again for a degree which they do not receive when unsuccessful but which they pay for as if they did. I have before me a letter from a gentleman who says he is a student of the late Queen's University, that he was unsuccessful at the last degree examination, and that he is now informed by the secretaries that he must now pay the fees again and present himself for examination in *additional subjects*!! Is this fulfilling the promise that these students would be examined under the old Queen's rules? On their behalf, I ask the Senate at their next meeting to give these matters their serious consideration; and wish again to urge on them the desirability of obtaining power to confer a registrable obstetrical qualification; and I desire to thank you, Sir, for your kindness in allowing me to discuss these resolutions in your columns.

Yours, &c.,

CHARLES FREDERICK KNIGHT, M.D.

91 Harcourt Street, Dublin,
4th December, 1883.

South London School of Pharmacy.—The following prizes were awarded to the successful competitors at the School

examinations terminating the 7th Dec., 1883, and presented on the 21st ult.:—Senior Chemistry Medal, Mr. Burford; Certificate, Miss Flora Mitten. Junior Chemistry Medal, Mr. Williams; Certificate, Mr. Heaver. Botany Medal, Mr. Wilkinson; Certificate, Mr. Burford. Materia Medica Medal, Mr. Heaver; Certificates, Messrs. Williams and Wilkinson (equal). Pharmacy and Dispensing Medal, Mr. Heaver; Certificate, Mr. Turner. Extra Certificates, Messrs. Dutton, Hall, Taylor, and Pomeray.

Notices to Correspondents.

✂ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE ROGERS TESTIMONIAL FUND. (EIGHTH LIST.)

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The following additional subscriptions have been received since the announcement in last week's number of the *Medical Press*.

Yours, &c.,

J. WICKHAM BARNES, Hon. Sec.

Poor-law Medical Officers' Association,
8 Bolt Court, Fleet Street, London, December 31, 1883.

X. has forgotten to enclose his card; this is a rule we always insist upon, especially when the letter is in the nature of a personal attack. Our correspondent's charge may be well-founded and *bona fide*, but we must have name and address as evidence of good faith.

A WIDOW.—As the relic of a deceased member of the profession, your claim would receive more consideration. There is a much lower scale of fees demanded for the sons of deceased members at the Epsom College, something like 25 per cent. less than for the general public.

DR. PATERSON (Perth).—Proofs will be sent you in due course; probably in about a month's time.

SEWAGE AS AN EVANGELISING AGENT.

THE *Sanitary Engineer* of New York is responsible for the following amusing mixture:—A reporter had to attend two meetings, one for the conversion of the Jews to Christianity, and the other, which followed immediately after, was on the subject of conversion of sewage into lime and cement. In the printer's hands the folios got mixed up, and the report read:—"The Chairman, after the meeting had been opened with prayer, explained that the conversion of the Jews was one of the greatest works that could engage the attention of our sanitary authorities. Filtration was the most perfect method that could be adopted for purification, but a filter had its limits. There was a popular notion that the sewage contained a vast amount of wealth, but the sludge must be taken out of it for purposes of irrigation, as it otherwise choked the pores of the land, and they were a wandering race spread over the whole face of the habitable globe. They were denied the inimitable blessings of Christianity, which might be counted by thousands of tons per annum allowed to run to waste, when by a judicious admixture of lime and clay, the benighted Hebrews who sat in darkness might easily be converted into lime and cement for building purpose, and if thus deodorised, after being first dried and burned in a kiln, this ancient race would once more take its proud position among the nations of the world. Subscriptions were earnestly solicited for the purpose, though he (the speaker) disclaimed any idea of making a profit out of the process, and, in conclusion, he urged increased efforts in the good work, showing that, thus deodorised by a very novel process of evangelisation in large tanks constructed for the purpose, the grateful Hebrews might flow over the land without injury to vegetation, while the expense of conversion, which was progressing as rapidly as the best friends of Christianity could wish, would be more than repaid by the sale of the phosphate of lime and valuable cement for building purposes."

DR. SALTER.—The view we take is the one all but universally held in the profession, and is most assuredly the only one tenable on the subject. Your letter is only a sample of very many that have been written to us in this connection, and the expressions of surprise it contains are nearly synonymous with those of numerous other writers. We are obliged for the offer made.

DR. DIXON, MR. SEDGLEY, MR. W. R. EDWARDS, DR. K., DR. F. E. V., MR. TAYLOR, and MROK.—See answer above to Dr. Salter.

MR. MARSACK (Tunbridge Wells).—Your interesting case shall appear in an early number.

INDEX.—The work is too voluminous, and we could not recommend it for your purpose; Bryant's, Gant's, or Holmes' smaller text-books on surgery would be preferable.

S. P. R.—The drug referred to is of Mexican origin, and as it has but recently been upon the English market, we have had no personal experience of its effects. You can get it doubtless for experimental purposes of any of the leading drug houses.

DR. W. H. P.—We will examine the essay and send you a private note.

DR. WHITE will please receive our best thanks for the information.

M. LE DR. RICHELOTZ (Paris).—The *cliches* will be acceptable, and the article interesting this side of the Channel. It will afford us pleasure to undertake the translation.

MEETINGS OF THE SOCIETIES.

THURSDAY, JANUARY 3RD.

ROYAL INSTITUTION.—At 8 p.m., Professor Dewar, On Alchemy in relation to Modern Science.

HARVEIAN SOCIETY.—At 8.30 p.m., Dr. T. Calcott Fox, On Urticaria in Infancy and Childhood.—Mr. G. Cowell, On the Treatment of Purulent Ophthalmia of Infants.

FRIDAY, JANUARY 4TH.

PATHOLOGICAL SOCIETY OF LONDON.—At 8.30 p.m., Annual General Meeting for Election of Officers, Report of the Council, &c.—The following preparations will be shown:—Three Examples of Pancreatic Disease; Further Specimens of Vacuolation of the Liver; Entozoon in the Lungs of an Animal; Epithelioma of the Ear; Medullary Sarcoma of the Skull of a Child.

SATURDAY, JANUARY 5TH.]

ROYAL INSTITUTION.—At 8 p.m., Professor Dewar, On Alchemy in relation to Modern Science.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At 8 p.m., Mr. T. Pickering Pick, Case of Stone in the Female Bladder.—Dr. Clippingdale and Messrs. Potter and Lunn, Cases of Morbus Coxæ.—Mr. Hendley, On a Case of Ammoniated Mercury Poisoning.

MONDAY, JANUARY 7TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At 8 p.m., Annual General Meeting for the Election of Officers for the ensuing Session.—Casual Communications by Mr. Morton Smale and Mr. Storer Bennett.—Paper by Mr. Bland Sutton, On Comparative Dental Pathology.—Valedictory Address by the President.

Vacancies.

Birmingham General Dispensary.—A Resident Surgeon. Salary, £150, with £30 for extras, no board. Applications to the Secretary before January 15.

Granard Union, Street Dispensary District.—Resident Medical Officer. Salary, £186. Election, January 8.

Marylebone Infirmary.—Assistant Medical Officer. Salary, £130, with furnished apartments and board. Applications to be made this day (Wednesday) to the Clerk of the Guardians, Marylebone Ed., London, W.

Appointments.

CUMMINS, W. E. A., M.D., M.Ch.Q.U.I., Visiting Physician to the Cork Workhouse.

GARDNER, P. H., M.R.C.S., House Surgeon to the Royal Portsmouth, Portsea, and Gosport Hospital.

GRIFFIN, J. M.B., C.M. Ed., Senior House Surgeon to the Royal South Hants Infirmary.

GUNN, C., M.D., M.Ch.Q.U.I., Visiting Surgeon to Jervis St. Hospital, Dublin.

LIPSCOMBE, A. A., M.R.C.S., House Physician to the London Hospital.

FELLM, H. L., L.D.S. Eng., House Surgeon to the Dental Hospital of London.

ROBINSON, M. K., M.D. Erlan., M.R.C.S., Medical Officer of Health for the Blean, Bridge, Dover, East Ashford, Eastry, Elham, Thanet, and West Ashford Rural Sanitary Districts, and the Dover, Herne Bay, Hythe, and Broadstairs Urban Sanitary Districts.

ROBERTS, G. A. E., Assistant House Surgeon to the Royal South Hants Infirmary.

SHAW, L. F., M.B. Lond., House Surgeon to the Victoria Hospital for Children, Queen's Road, Chelsea.

SINCLAIR, B., Medical Officer for the Parish, and Sanitary Officer for the Borough, Inverary, Perthshire.

WALKER, W. H. S., L.K.Q.C.P.I., L.R.C.S., &c., re-appointed Resident Medical Officer to the Hospital for Sick Children, Glasgow.

Births.

BEVERIDGE.—December 23, at Totnes, Devon, the wife of H. T. S. Beveridge, M.D. Ed., E.N., of a son.

Deaths.

HARDING.—December 24, at his residence, Eagle House, Hornsey, N., John Fosse Harding, F.R.C.S., aged 75.

HOUSEMAN.—December 20, at 68 Jesmond Road, Newcastle-on-Tyne, John Houseman, M.D., L.R.C.S. Ed., M.R.C.S., aged 72.

FRING.—December 16, at Pwllheli, Peter Burnett Fring, L.R.C.P. Ed., M.R.C.S. Eng., aged 33.

WHEELER.—December 19, at his residence, St. Lawrence-on-Sea, Thomas Rivington Wheeler, F.R.C.S., aged 65.

WRIGHT.—December 21, at St. Neots, Hants, Samuel Wright, M.R.C.S., F.L.S.

A CASE OF GUNSHOT INJURY WITH UNUSUAL THORACIC COMPLICATIONS.

By WILLIAM STOKES,

Professor of Surgery, Royal College of Surgeons; Surgeon to Richmond Surgical Hospital.

A TWO-FOLD reason actuates me in bringing the following case of gunshot injury under the notice of the Surgical Section of the Academy. The first is that from the happy rarity of such cases here, and the peculiar signs and symptoms in this particular one, it is likely to prove of interest; and the second is the hope I entertain that certain thoracic phenomena observed in it, and of which I find it difficult to offer explanation, may, and I trust will, be elucidated by some of the academicians here this evening.

On Sunday afternoon, September 16, Mr. J. M., at about 36, a clerk in the Ordnance Survey Department, was admitted into the Richmond Surgical Hospital, suffering from a gunshot injury which he had accidentally received about an hour previously. The wound was received near Cabra, about a mile from the hospital, and he was able to walk there without assistance, arriving at 7.30 p.m.

On examination, a bullet wound was found over the left scapula about an inch from its vertebral edge and two and a-half from the inferior angle. There had been no hæmoptysis and very little external bleeding; but the patient was pallid and weak, complained of great difficulty in breathing, and said he felt as if his heart was "getting paralysed and had not sufficient room." The patient was put to bed but did not remain in it for more than a few minutes as he said he felt himself "getting smothered." He could, undoubtedly, breathe much more easily standing or sitting upright, in which position he remained for several hours. At 10.15 p.m., Dr. Thornley Stoker, in my unavoidable absence from town, kindly visited the patient, and on probing the wound found that it passed outwards and slightly

forwards. On percussion, the area of cardiac dullness was found to be sensibly increased. There was a distinct tumour about an inch or an inch and a-half below, and to the right of, the left nipple, and over which a remarkably distinct crackling or crepitating sensation could be felt. The tumefaction was of an area as large as the circumference of a Tangerine orange and had enough prominence to be distinctly visible. Over this loud gurgling sounds could be heard. "The supposition in my mind," Dr. Thornley Stoker observed, "was that blood and air were present either in the pericardium or sufficiently near to it to receive marked impulse from the heart. The sound was a loud gurgling, such as the bursting of gigantic bubbles would be likely to produce, and was distinctly audible at a distance of ten feet from the patient. There was dullness in the lower part of the pleural sac."

Shortly after his admission his temperature was 96 deg.; pulse 80; and respirations 56.

During the night the patient slept very little, was greatly troubled with cardiac spasms, dyspnoea, and intense thirst.

At 10.30 a.m. I saw the patient for the first time. His face was somewhat flushed and had an expression of great anxiety. The pulse, 120; temp., 101.5 deg; resp., 56. On the anterior surface of the chest, at a point corresponding a little to the right of the situation of the cardiac apex, was a distinct tumefaction not so prominent, I was informed, as on the previous evening, but increased in width. On making gentle pressure over it a distinct crackling sensation was communicated, suggesting simultaneously the ideas of fracture and emphysematous crepitus. Over and in the immediate vicinity of this were heard distinct friction sounds, which I believed were due to pericardial inflammation, a view which subsequent investigation did not verify. The left side was found, on percussion, to be absolutely dull except at a small space about two inches in diameter situated a little to the left of the cardiac base and which was found to be not dull but distinctly tympanitic. The respiratory sounds were feeble, particularly so on the inferior and posterior aspect of the

chest wall. The pulse, temperature, and respirations remained unchanged during the day. The patient was ordered mercury, grey powder in 3-grain doses thrice daily.

The following morning, September 18, the patient was found to have slept a little, but no material change was observed to have taken place; the temperature, pulse, and respiration in the morning being 101.2, 127, and 42 respectively, and in the evening 101.3, 130, and 40. The patient's thirst was very great, as well as the pain over the anterior and lateral portions of left side of chest. Large linseed-meal poultices were ordered to the chest, and ice to allay the thirst.

On September 19 I found the patient in a condition of extreme exhaustion; the dyspnoea had greatly increased, and the horizontal position was no longer tolerable. He had to be raised up and well supported by pillows. The temperature rose during the day to 104.3 deg.; the respirations to 44; and the pulse to 130. The heart's action was very weak, and both respiratory and cardiac sounds very feeble. Towards evening the patient became somewhat delirious. At our President's (Dr. Banks) suggestion, he was ordered pills containing grey powder, quinine, and digitalis.

The day following (September 20) the patient was found to have had a very bad night, the symptoms of dyspnoea, cardiac distress, &c., all being increased. During the night, too, the bowels were moved six times; the temperature, pulse, and respiration in the morning being 100.2, 140, and 48 respectively, and in the evening 102, 134, and 36. On examination, there was found to be considerable fulness on the left side, with displacement of the heart towards the right side. There was great difference in the radial pulses, that on the left side being considerably feebler than on the right. The respiratory sounds were very feeble, especially on the posterior aspect of the lung on the left side. On comparing the two sides of the chest by measurement, the left was found to exceed the right by one and a-half inches. That on the right side being seventeen inches, and on the left eighteen and a-half inches. The evidences of effusion being so clear, I tapped the chest with a Dieulafoy's aspirator and drew off fifty-six ounces of a dark reddish serous fluid, on letting which stand, no blood coagula formed. The operation was attended with immediate and great relief to all the symptoms. Pulse became stronger, and the difference between the radial pulses was no longer to such an extent perceptible. The breathing became easier. The patient became much more cheerful and hopeful of his ultimate recovery, and his face lost the expression of anxiety it had from the time of his admission into the hospital.

For the next few days this satisfactory condition of things continued; pulse, temperature, appetite, freedom from pain, power of sleep, and hopefulness on the part of the patient, all being such as to make my colleagues and myself entertain favourable anticipations as to the result. These anticipations, however, were not to be realised.

On Tuesday morning, September 25, the dyspnoea again became very urgent. The cardiac dislocation was considerably increased. Pulse and temperature rose; and much distress was caused by cough, accompanied with profuse bronchial expectoration, but untinted with blood. Heart's action and respiratory sounds became very weak. Moist râles could be heard on both anterior and posterior aspects of right side of the chest. A consultation of my surgical colleagues, Drs. Thomson, Stoker, and Corley, with Dr. Banks and Dr. Gordon, was held, to determine if paracentesis should be again performed. A decision not to perform it was come to, chiefly on account of the condition of the right lung which was rapidly filling with catarrhal secretion, and the condition of extreme prostration the patient was in.

A 3 o'clock p.m., the patient was suddenly much worse. His face got congested, swollen, and almost purple in colour. He was bathed in profuse perspiration, and the dyspnoea was painful in the extreme to witness. Hot turpentine stupe, Hoffman's ether, brandy, and turpentine were given in small quantities at short intervals; but the patient got worse and worse, and at 12 p.m. he became delirious in which state he remained until 2.30 a.m. when he died.

The autopsy, made by Dr. Thornley Stoker, who saw this remarkable and exceptional case in the first instance, and who throughout took a very deep interest in its progress, was performed nine hours after the patient's death. The wound was situated apparently an inch from the vertebral edge of the left scapula, and two and a-half inches from its inferior angle. On introducing a probe, it was found to pass forwards, outwards, and downwards, piercing the scapula about an inch from the inferior angle. The bullet then was found to have entered the thoracic cavity between the seventh and eighth ribs, splitting the lower border of the seventh rib and fracturing the eighth rib. At this point was found a small portion of cloth evidently belonging to his clothing, which formed there a plug. Some splinters of bone were also found in this situation. Here, also, we came on a large abscess burrowing among the adjacent muscles. There was a large collection of grumous fawn-coloured fluid in the pleural sac, and the lung greatly, in truth, almost completely, collapsed. The bullet was found to have penetrated this, passing through the superior border of inferior lobe, and emerging at the anterior border over the pericardium, and was lodged in the angle between the diaphragm and the sixth intercostal muscle in the line of junction of the cartilage with the ribs, and surrounded and retained there by a mass of recent lymph. Of this there were copious deposits, not only on the pleura, but also numerous flakes of it were detached and floating about in the enormous pleural effusion. On the right side the pleura was normal, but the lung was congested, emphysematous, and with numerous hemorrhagic infarctions. There was no evidence of any pericardial complication.

The latter fact proved that I was in error in supposing that the remarkable loud friction and crepitating sounds were partly, if not altogether, due to traumatic pericarditis, and that the subsequent gradual subsidence and ultimate disappearance of them was due to effusion separating the serous surfaces from each other. In place of this the pericardium was found normal, and the loud friction sounds were obviously connected with pleuritic and not pericardial inflammation, thus affording a signal illustration of the difficulty that, at times, attends the differentiation of the friction sounds of pericarditis from those of pleuritic inflammation. In this case the collapsed condition of the lung doubtless prevented observance as to whether there was any correspondence between the friction sounds and the pulmonary motions, thus intensifying, in consequence, the difficulty of diagnosis.

A remarkable feature to be noted, also, was the subsidence, for several days, of dyspnoea, notwithstanding the existence of so copious a pleuritic effusion, and also the absence of succussion sounds, although at the commencement, at all events, of the case, a double portal, by which air could enter the cavity of the pleura, existed—one being the wound in the chest, and the other that in the lung.

The phenomena, however, which are to my mind of most interest and greatest difficulty of explanation were the remarkable tumefaction situated to the right of the left nipple, which was observed on the patient's admission into hospital, and from which were heard—even at a considerable distance—the loud gurgling, bubbling sounds already mentioned; the gradual subsidence and ultimate disappearance of this tumefaction, as well as th

sounds connected with it, and also the persistence, on gently pressing the situation of the tumour, of that peculiar form of crepitation which was well compared by Dr. Banks to what one experiences on walking on crisp snow during a hard frost.

Again, the remarkable area of tympany observed in front of the chest when the patient was in the horizontal, but disappearing and becoming absolutely dull when in the erect position, is extremely difficult of explanation, and the information afforded by the autopsy in reference to this was, to my mind, distinctly negative.

The case is of importance, too, as illustrating the greater danger attending gunshot fractures of the ribs when the lesion is produced at the point of entrance of the missile. This fact has been strongly emphasised by Surgeon Brinton, whose remarks are quoted in the splendid "Medical and Surgical History of the War of the Rebellion," by Surgeon-General Barnes, United States Army. Mr. Brinton observes that an unfavourable prognosis might be almost uniformly given when a ball struck a rib on entering, deflected inwards the sharp points of the broken rib and drove before it bony spicules; whereas, if the projectile passed in through an intercostal space, and fractured the ribs on emerging from the thorax, far less apprehension need be felt." P. 488.

The only other point I would allude to is, in reference to treatment, and on this I shall be very brief. As regards instituting any search for the missile, having regard to our necessarily complete ignorance as to its whereabouts, and to the vital nature of the parts we had to deal with, I do not think that even so daring an operator as the late Marion Sims—whose recent death all interested in the progress of surgery must deplore—and whose views in reference to the treatment he thought should have been adopted in the case of President Garfield are doubtless well-known to all present, would—even while adopting the most rigid antiseptic precautions—have proposed or sanctioned any such procedure.

I consulted several of the standard works of British military surgeons for the record of any case similar to the foregoing one in the hope of obtaining light or leading in reference to either its pathology or treatment, but my search was, as I anticipated, somewhat like an attempt to draw water out of a lime kiln—fruitless. The treatment that was adopted was, in the main, anodyne and supporting. The only operative interference carried out being the paracentesis, and in reference to this, the question might reasonably be raised as to whether it would not have been wise to insert perforated tubing, and kept up drainage, adopting at, and subsequent to, the operation, the strictest Listerian antiseptic precautions and dressings, the importance and necessity for which in all such cases has recently, I may observe, received a fresh impulse in the Address on Gunshot Wounds, delivered in Bellevue Hospital Medical College, New York, by our eminent countryman, Sir William MacCormac.

I did contemplate adopting drainage at the time I performed paracentesis, but at the close of the operation, the patient became so weak that I did not deem it prudent to proceed any further.

Such are, briefly stated, the main facts connected with the history of the foregoing remarkable instance of gunshot injury, an analogue to which I have searched for in vain. It is, in truth, rare to find a case presenting unusual but clearly defined physical phenomena in which post-mortem investigation has not succeeded in throwing a ray of light to penetrate the obscuring mist. In this instance, however, in many particulars it failed to do so, and consequently the phenomena already referred to, the absence of hæmoptysis, the tumefaction over the heart observed immediately after the accident, and which subsequently disappeared, the loud gurgling bubbling sounds connected with it and heard at a distance from the patient, the area of tympany observed

on the anterior surface of chest when patient was in one position and disappearing when in another, and the absence of succussion sounds; these, while doubtless offering ample scope for speculative ingenuity, must, so far at least as I am concerned, for the present remain unexplained.

Lectures

ON

THE DIFFERENT FORMS OF APHASIA— TYPE, BOUILLAUD BROCA.

By J. M. CHARCOT, M.D.,

Professor to the Faculty of Medicine, Paris; Physician to the Salpêtrière Hospital; Fellow of the Clinical Society of London, &c.

(Concluded from page 240 last vol.)

GENTLEMEN,—This is sufficient regarding the clinical study of our case. It now devolves upon us to determine as much as possible the anatomical substratum of this affection of language so remarkably limited and circumscribed. At the outset two questions present: Where is the seat of the pathological change? In what does it consist?

You are all conversant with the valuable researches of Bouillaud, of Dax, and of Broca relatively to the localisation of articulate speech. Consequently I can dispense with any formal discussion on this matter in order to arrive at the conclusion that in the case of our patient there is a lesion at the foot of the third frontal convolution on the left side or its anatomical dependencies. There is nothing better established at least, so far as concerns the form of aphasia which we are considering at the present moment, than that localisation of Broca not long ago so little discussed. Contrary opinions have not been wanting, and have been even published in considerable number. But few of these withstand criticism, and I agree with the conclusions arrived at by Dr. Broadbent in his valuable paper "On the Cerebral Mechanism of Speech and Thought." (a)

With him, I have never encountered a veritable exception to the law of Broca, and with him, I do not believe that any of the cases presented as annulling it will bear serious examination. Among these, as Dr Broadbent has justly remarked, there is a certain number which are written under the aphasic rubric which are cases of labio-glosso-laryngeal paraplegia, of dementia, or of apoplectic stupor; others of genuine aphasia without destructive lesion of the third left frontal convolution, but in which the Sylvian artery has been obliterated by a thrombus, and where consequently the absence of an aphasic complication, at least transitory, had constituted, on the contrary, an exception to the rule. Others, again, where the pathological change did not affect the grey cortex of the convolution but rather the subjacent white fibres, which as we shall see, amounts to almost the same thing. In another class of cases, where no aphasia occurred, it has been stated that the convolution of Broca was diseased. This, however, has been based on an imperfect knowledge of cerebral topography, as the region designed has not been that to which, properly speaking, this name applies.

Further, in the group of contrary observations there is reason to exclude the cases of lesion of the third frontal convolution without aphasia, but occurring in left-handed subjects; and the cases also in left-handed subjects in whom aphasia coincided with a lesion of the third right frontal convolution. Quite recently, at the Clinical Society of London, (b) Dr. Taylor recorded an example of the first kind, and (c) Dr. Habershon an example of the second. It is the same regarding these

(a) "Med. Chir. Trans.," 1872, p. 172.

(c) Loc. cit., p. 101.

where, notwithstanding the existence of aphasia and that the subject thereof was not left-handed, a lesion of the third left-frontal convolution is discovered, dating from early infancy. One is forced to the conclusion that in such circumstances a functional substitution is established, the third right frontal convolution fulfilling the functions of its homologue on the left side. (a)

Another cause of error consists in that when speaking of aphasia one neglects to keep in view its varieties. Thus, to cite only one example, in the affection written of under the term *word-blindness*, in consequence of the more or less complete suppression of the auditive representation of words, certain aphasic complications may be begotten where the articulation of language is concerned only secondarily by some kind of *contre-coup*. At times, as we shall see, it is one of the temporal convolutions of the left side which is originally implicated, and a lesion of the convolution of Broca is consequently not to be looked for.

It appears to me useless to follow out these observations further; for if at the present time the seat of the lesions to which we ascribe the perversions of language described under the terms *agraphia*, *word-blindness*, and *word-deafness*, is not yet in all its aspects definitely settled, this does not obtain in the case of aphasia called motor, ataxic, or logographic, the sole form which Bouillaud and Broca had in view in their studies, and of which the case with which I am about to present you offers an example remarkable alike by its purity and simplicity. This form of speech impairment demonstrates the rule almost universally acknowledged, I repeat, that there exists coincidentally a superficial or deep, transient or permanent, lesion, affecting either the grey cortex of the third left-frontal convolution or the white fibres which unite it to the nuclei of the olfactory bulb.

Allow me in this connection to recall to you in indicating in a more precise manner that part of the third frontal convolution which, according to the researches of Broca, specially regulates the function of

the articulation of language. You will observe (fig. 68) how the foot of the third frontal describes with tolerable regularity by its folds the figure of the letter M, whose two median limbs constitute the portion termed by Broca *the cape*. But it is either on the posterior limb or that which unites the inferior part of the ascending frontal to the rest of the third frontal that we must search for the lesion to which motor-aphasia is due.

When this lesion which we are considering is accurately circumscribed to this region the fact is demonstrable by certain observations; and that besides is explained in the majority of cases by the fact that in certain subjects the vascular territory of the third frontal convolution enjoys an autonomy at least relative, inasmuch as it is supplied by a special artery whose obliteration, sometimes transient, sometimes permanent, determines in the corresponding region of the cortex disorders easily recognised.

It is to be observed that in cases of small localisation the aphasic disorder manifests itself without being accompanied by any paralysis of the face or members. It was thus in a case, related by M. Legroux, (a) which occurred in my wards. The plate which accompanied the description and which I now show you (fig. 69)

FIG. 68.

FIG. 69.

indicates a *yellow patch* at the foot of the third left-frontal convolution. This occurrence reminds me of the case of the patient Lelong, published by Broca, and that which Rosenstein has related in the *Journal Hebdomadaire* of Berlin. (b) Without doubt, examples of this group might easily be multiplied; but a localisation as exact is truly a rare thing. In general, the lesion extends to the convolutions, which have neighbouring functions in common with the region of Broca. At the present time you will have no difficulty basing on the results acquired by the application of the anatomical method in determining what the consequences will be of the extension of the lesion to the regions whose *ensemble* constitutes what it is expedient and justifiable to designate the motor zone. It is thus that paralysis of

(a) "Atrophie Partielle du Cerveau," Cotard. 1868; p. 80.

(b) "Berliner Klin. Wochensh.," 1884, s. 182.

the ordinary movement of the tongue, of the inferior facial, of the upper extremity, and ultimately of the inferior extremity of the right side, either simultaneously or alternately becomes superadded to motor-aphasia when the ascending frontal convolution has become the seat of disease. Let us remain, gentlemen, firmly persuaded of these cardinal facts, confirmed daily by observation in human beings and against which certain contrary facts furnished by vivisection cannot prevail.

The region of the neighbouring island of the third frontal is frequently simultaneously affected. In these times, lesions of the island considered in their bearing on logoplegic aphasia have been much spoken of. Can this latter be, as has been supposed, the direct consequence of a lesion limited to the lobule of the island? The fact is, as pointed out by M. Boyer, (a) that in the cases brought forward to support this opinion it more frequently happens that sometimes the grey substance and sometimes the white sub-cortical bundles were affected simultaneously with the substance of the lobule. Some cases, however, do exist tending to establish the fact that the cortex of the lobule of Reil may exceptionally become, to the exclusion of the circumvolution of Broca, the substratum of the organization of movements of the tongue and lips in the articulation of words. I have had frequent occasion in the course of these lectures to remark that aphasic aberrations are equally produced in cases where the lesion of third convolution affects the grey substance, and in these where it has destroyed the subjacent white fibres which unite it to the nuclei of the bulb. Has this difference of localisation its corresponding cortical manifestation? or, in other words, can we distinguish clinically between motor-aphasia due to lesion of the cortical substance and motor-aphasia of sub-clinical origin? This is a question with which many observers have been engaged, and on which I purpose in my next lecture offering certain observations.

THE INDICATIONS OF TREATMENT IN ACUTE RHEUMATISM.

By BERNARD KELLY, M.D., L.K.Q.C.P., L.R.C.S.Ed.,
Medical Officer for the Fifth District of St. Olaves', Southwark.

(Continued from page 527, last vol.)

Now as to treatment. Nothing perhaps illustrates more clearly the wonderful ingenuity and, at the same time, the vast resources displayed by medical men in presence of a disease so protean and formidable as rheumatism, judging from the diversity, and, it must be confessed, the seeming disparity of the remedial means to which they have had recourse for its cure. Veratrum, colchicum, blisters, blood-letting, warm-baths, ice, quinine, chalybeates, mercurials, anodynes, alkalies, and acids—all have been tried in the treatment of rheumatism—all have succeeded and all have failed alternately, according, as I believe, the type or stage of the disease had, or had not, been duly appreciated and recognised by the physician, thus verifying the remarkable saying of Diocles: "Medicines are as nothing, or as the hands of God, accordingly as they are ignorantly or skilfully prescribed." Either the disease has greatly changed in its gravity or type since the palmy days—not to go further back into antiquity—of Sydenham, Bonilland, and Ohomel, or our mode of viewing it entirely differs from that of those distinguished pathologists, leading us to adopt a milder course of treatment, and to trust more in the resources of Nature; otherwise it would be difficult to account for the utter desuetude into which many of the remedies then in vogue—more especially venesection—have recently fallen. For my own part, I am strongly inclined to believe that the disease is unalterable—that it

is the same now, in every respect, both in type and character, as it was in the time of Hippocrates; and that the change in question is due solely and simply to the more general diffusion of sounder pathological doctrines, and the more exact observation and analysis of clinical facts. A change in the system of treatment, however, does not necessarily imply a step in advance, as it must show something besides mere novelty to recommend it, without which, after a full and fair trial, it inevitably falls to the ground to give place to another which may prove, perhaps, as ephemeral and visionary as itself. This something is success, true and unequivocal, which, I believe, the treatment now almost universally adopted can justly claim as the criterion of superior merit. What practitioner, I would ask, ever thinks nowadays of treating rheumatism by bleeding, blistering, and purging? Not that they are without benefit in certain special cases; but to employ them indiscriminately, and, as it were, preferentially, is entirely out of the question. The cases which require the lancet, calomel, black draught, *et id genus omne*, are so few and exceptional as to scarcely claim our serious attention. The only cases, indeed, which might, with any show of reason, justify their use are those complicated with pleurisy, peri- or endo-carditis, inflammation of the eye, brain, &c.; but even here, except in extremely robust and plethoric constitutions, milder and less drastic measures will generally suffice. As to blisters, one would suppose that they had been long since relegated to an eternal limbo, never to rise again, as cumbrous, cruel, and obsolete barbarisms of the past; but this is far from being the case. If able and enthusiastic advocacy can accomplish it, the blister treatment bids fair to regain its lost ground in therapeutics, and to supplant many of its more popular rivals. Thus, Dr. Herbert Davies says:—"Blisters well and early applied (while the fever is high and the pain most acute) around every inflamed joint and followed by large poultices, to favour the discharge of large quantities of serum, produce rapid and full alleviation of the pain, reduce the pyrexia quickly, and speedily restore the use of the painful joints, acting *cito, tuto*, and, I would almost say, *jucunde*." Dr. Davies is also quite confident that blisters thus applied prevent the migration of the disease, and especially metastasis, to the heart; that relapses become less frequent and less severe, and the duration of the disease is very materially shortened. They also (and this is very important) render the urine alkaline. We can better imagine than describe the intense suffering, not to say the exquisite torture, inflicted on a sensitive and delicate lady by the simultaneous application of, say, four or a half-dozen blisters to the joints; and may not be deemed guilty of unjust or harsh criticism when we pronounce the "remedy worse than the disease." But perhaps Dr. Davies has only the sterner sex in view. However, if all the advantages claimed for it be realised—and we see no reason whatever to doubt them—all objections, especially those of a sentimental nature, must weigh light in the balance, and disappear before the extraordinary results achieved.

In the treatment of disease in general (and this applies most particularly to rheumatism) our chief aim should not be so much to shorten its duration as to conduct it, by guarding against and preventing serious complications, to a safe issue. Indeed, in our anxiety to limit its duration, we are only too apt to ignore and set aside the recuperative powers of Nature, and by embarking upon a speculative system of medication, we often run the risk of dashing against the rock we would fain avoid. There is, and can be, no fixed, definite, or specific line of treatment for any disease, as every case, however similar in general characters, must be met on its own merits, and treated accordingly. No other affection, perhaps, offers a more striking instance of the inexorable logic of this rule than does acute rheumatism, as there is, perhaps, no other so protean in its character, or so variable and diversified in its duration, course, and complications. Thus in the early stage of the disease, when the pyrexia is at its height, as shown by the increased temperature, thirst, dry skin, quick

(a) Dr Boyer, "Études Cliniques sur les Lésions Corticales des Hémisphères Cérébraux." Paris, 1879.

bounding pulse, &c., it would be highly injudicious, not to say, dangerous, in my opinion, to prescribe stimulants and ferruginous preparations, especially the acid forms, or persalts, as such remedies—all theories advanced in their favour notwithstanding—would be almost sure to end in disastrous failure. Hence refrigerants, saline aperients, diaphoretics, and alkalies especially, are clearly indicated, and have been prescribed from time immemorial by the ablest and most distinguished lights of the profession, proving that empiricism is not only often right, but even not unfrequently outstrips the tardy and cautious advance of experimental and positive science, and traces out the true path to follow. The alkalies are pre-eminently curative, as they not only act as antiphlogistics, by retarding or entirely checking metabolism, or tissue change, but they neutralise the acid products of combustion as rapidly as formed, and, by rendering them more soluble, hasten their elimination from the system. They also protect the alkaline constituents of the blood, or replace them, if already removed, thereby preventing the great emaciation and anæmic phenomena so conspicuous and constant in the course of acute rheumatism. They also, so far as I have observed, not only cut short the ordinary duration of the disease, but they very effectually prevent, in the majority of cases, the secondary complications of remote organs, such as the lungs, heart, and brain.

Seeing that the alkalies of the blood are all indiscriminately attacked by the uric acid, one would naturally suppose that it would make very little difference as to which of them we might select as remedies in the disease; but this is far from being the case, as we learn to our disappointment and bitter cost from practical experience—lime, soda, ammonia, and magnesia occupying the lowest grade in the scale of therapeutic agents, while potash and lithia take the highest rank. This may be owing to the fact that the chemical combination in salts, resulting, from the latter class being more soluble are the more readily eliminated from the system; while the former, being comparatively insoluble, are, in a great measure, retained, and act as local irritants to the parts with which they come in contact. The reverse of this, strange to say, obtains in gout—ammonia, soda and magnesia being, according to my experience and observation, the most effectual remedies; while potash and lithia are, at least, but feebly palliative.

These remedies (alkalies) should be continued so long as the urine and perspiration show an acid reaction, or even for some time subsequently; for it is very remarkable how rapidly the acidity of the excretions in question reappears, when we too hastily, or abruptly, suspend their administration. As, however, the saline constituents of the normal healthy urine are capable of decidedly reddening litmus paper, and thereby leading us, unless well on our guard, to suppose that the effect in question is due to morbid acidity, we should test the suspected fluid by a solution of the bicarbonate of potash, not the liquor, for obvious reasons. When, if acidity be really present, effervescence, more or less brisk, immediately ensues. But their too-prolonged use is not without some danger, although of the two evils I would choose the latter as the safer and less objectionable, as they sometimes lead, directly or otherwise, to a protracted convalescence. It is here where the good judgment and the acumen of the practitioner are severely tested; and, in the ordeal, either signally fail, or conspicuously show themselves. Should the tongue be clean and moist, the pulse soft or compressible, the temperature natural or sub-normal, the appetite keen or fairly good, the local pains entirely absent or much abated, the morning remissions well established, and contrasting favourably with the evening exacerbations, and the urine neutral or decidedly alkaline, there can be little doubt of the propriety or necessity of a change in the basis of treatment. Here chalybeate tonics, ammonia, bark, &c., are clearly indicated, and will be found, on trial, to meet our most sanguine expectations. Here, especially, the persalts of iron and quinine, separately or in combination, and

given in heroic doses, will, in the great majority of cases, leave little or nothing to be desired so far as promptness of action and therapeutic efficacy are concerned.

When the disease is not met with in the chronic form, or assumes it, as it occasionally does in some phlegmatic constitutions despite all treatment, no remedy, so far as I have observed can equal, or even approach, in energy, the iodide of potassium, in combination with quinine, both substances being given in as full and large doses as the system will permit. Should quinine be not tolerated as is sometimes the case, whether given in large or small quantity, ammonia may be safely and appropriately substituted, as it has the great (double) advantage of covering the disagreeable, nauseous taste of the iodide, and of increasing, so far as I can judge from a rather extended experience, its therapeutic efficacy. Here, too, counter-irritation to the joints, in the form of iodine, sinapisms, and stimulating embrocations (blisters rarely), is clearly indicated, and very materially assists the constitutional treatment in arresting inflammatory action and promoting the absorption of serous effusion and fibroplastic material deposited in the parts. Indeed, without it, the latter not unfrequently fails, or may be said to "drag its slow length along." In very feeble and cachectic subjects, steel-wine and chalybeates in general, combined with cod-liver oil, when there exists much emaciation or when the digestive organs are capable of assimilating it, are eminently serviceable, for otherwise it (cod-liver oil) is sure to do more harm than good, by exciting nausea, vomiting, and occasionally, purging. Still, I am disposed to think that much of the intolerance met with in daily practice regarding the use of oil is often rather due to the careless and very perfunctory manner of prescribing it, than to any idiosyncrasy or want of moral courage and perseverance, on the part of the patients. We are all of us, unfortunately—so much are we the slaves of custom and routine—only too apt to look upon cod-liver oil as a powerful specific, not only in all stages of phthisis, but in all diseases marked by asthenia and strumous taints, that we almost instinctively employ it as our sheet-anchor—our *refugium peccatorum*!—quite regardless as to the proper time of its administration, and oblivious of the patient's constitution and ability to digest it. It is in this way, I am fully convinced, that our most valuable therapeutic agents are often unjustly condemned, or fall into disfavour, through no intrinsic fault of their own, but simply from the thoughtless and slovenly manner of their application and employment. The consequence is that in a very large majority of cases, we are obliged to suspend it; or when we enforce it contrary to the feelings and repugnance of our patients we find to our surprise, and, it may be, our regret, that they often unceremoniously withdraw themselves from our supervision. When I am thoroughly satisfied that oil is the only remedy in any case, I take care to prescribe it—at least, to begin with—in minimum doses, say, a teaspoonful three times a day; and when tolerance is shown, to gradually increase the quantity. Another mistake, I think, often made is by giving it immediately before or after meals. This very often excites nausea and vomiting, and produces an insuperable disgust in the minds of patients against it. This is very easily rectified, for by waiting two or three hours after meals, or about the time that stomach digestion is ended, and intestinal begins, the oil rarely induces any unpleasant effect, and is probably assimilated or, at least, saponified or emulsified, after the chyme has passed the pylorus.

In conclusion, I purpose saying a few words on the salicylic treatment of rheumatism.

The effects attending the use of the salicylate of soda (for it is the only form I invariably employ) may be briefly stated to be rapid defervescence and analgesia, which usually ensue from twenty-four to forty-eight hours from the outset; slowing of the pulse; diminution of uric acid and urates in the urine, which, however, is not accompanied, so far as I have observed, by an increase of the secretion. But then, *per contra*, there

appear, with equal suddenness, *tinnitus aurium*, deafness, vertigo, sub-delirium, insomnia, and so forth. The pupils, if anything, become somewhat dilated, without, however, intolerance of light or dimness of vision supervening. The patients not unfrequently experience a vague indefinite apprehension of some impending evil; so much so that, to use their own words, "they are afraid to close their eyes." The analgesic effect of the salicylate exerts, I believe, a powerful moral influence upon patients towards curtailing the duration of the disease. They recover, to all appearance, rapidly, simply because their pains rapidly subside—*Possunt quia posse videntur*. But, unfortunately, herein lurks an unforeseen source of danger, and which if not guarded against may lead to serious complications and relapses. The patient should, therefore, be kept closely to his bed for several days after the symptoms, both general and local, of the disease have disappeared. In this way he will escape much unnecessary suffering; and the treatment, the discredit of failure which otherwise would surely attach to it.

The tinnitus is often so severe and amazing as to be compared to the ringing of church bells, the blowing of steam whistles, and the like. This, with the delirium, spectral illusions, and other hallucinations, quickly subsides on the suspension of the drug; or, which I consider a better plan, as it maintains a show of treatment, by giving it in minute doses, say, a teaspoonful of solution (equivalent to three grains) every three hours. The pyrexia (for I have rarely met with a temperature that could be dignified by the name of hyperpyrexia) and the pain and swelling of the joints usually disappear in from twenty-four to forty-eight hours from the commencement of the treatment.

The action, physiological and therapeutical, of salicylate of soda is *sui generis* entirely different from that of opium, belladonna, or any other anodyne or alterative I know of. By lowering the temperature and depressing the heart's action, it arrests the undue oxidation of the nitrogenous or fibrous tissues of the system, and consequently the excessive production of urea and uric acid, the latter more especially. This is shown on examination of the urine, however superficial, which, in the large majority of cases, will appear clear and limpid. It also rapidly becomes neutral or alkaline, and quite free from sand or lateritious deposit. Owing to the promptness with which the ordinary duration of the disease is shortened, very little emaciation or anæmia results, and the convalescence is equally satisfactory. The drug, in a word, is anti-rheumatic in the same sense, and quite to the same degree, that mercury and the iodide of potassium are anti-syphilitic or the sulphate of quinine anti-periodic.

From my experience of the action of the drug, I should hesitate very decidedly in giving hourly doses of ten or twelve grains, as recommended and practised by some writers on the subject. I have never failed to produce all the constitutional and therapeutical effects of the salicylate by ten, or, at most, twelve grain doses administered every three hours. Even with this comparatively small quantity, alarming cerebral symptoms (salicisms) not unfrequently occur, when its immediate suspension, or lessening of dose, becomes absolutely indispensable. Tinnitus, deafness, delirium, and other nervous phenomena subside with remarkable celerity, by merely taking the precautions mentioned. Instead of endeavouring to counteract the depressing effect of the drug upon the heart and muscular system in general by the administration of nutrients and diffusible stimulants, I much prefer withholding it altogether; or, which may be better (as it conveys at least a show of treatment) give it in minute doses and at prolonged intervals.

I have never observed any serious derangement of the stomach or alimentary canal, characterised by nausea, vomiting, or purging attend its use, when employed in the manner indicated. Our object, as already asserted, in treating all diseases, and rheumatism especially, should not be so much to limit their duration, as to conduct them to a safe issue.

Nothing, perhaps, demonstrates more clearly the pathological relationship, if not identity, of gout and rheumatism, than the behaviour of salicylate of soda in both affections. Indeed, so far as I have observed, it would be difficult to say which complaint is more speedily and effectually relieved by its action. In illustration of this, I could adduce some remarkable examples, but as this paper has already fully reached the length I originally intended it should, I shall postpone their consideration for a future, and, perhaps, more fitting occasion.

Rotherhithe, Nov. 29th, 1883.

Clinical Records.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

Suppression of Urine—Convulsions—Death.

Under the care of Dr. ARMAND SEMPLE.

Notes by G. TULL, TREVOR, Registrar.

R. G., a girl, æt. 2 years and 2 months, was admitted into the Connaught ward on October 17th, 1883.

Family History.—Father and mother healthy. There are four children alive. Mother has had one miscarriage.

History of present attack.—The child has been ill since the 15th of October, when the mother noticed that its legs were swollen. It also had a sore throat and cough. The mother says that it passed no water for eighteen hours on October 16, and that the little it has passed during the last two days has been very thick. The father had a sore throat last week. There are no bad smells about the house. The child has never had scarlet fever; nor is there any scarlet fever in the immediate neighbourhood that the mother knows of.

On admission.—Child looks ill. The legs and feet are swollen. Breathing very rapid. There are rhonchi all over the chest with coarse crepitations here and there. Heart sounds healthy. Pulse 130 per minute, very feeble. Cries a good deal when examined.

Almost immediately after admission the child became much worse. The breathing became very difficult. Ordered one teaspoonful of brandy every two hours, and two teaspoonfuls of ammonia and ipecacuanha mixture every four hours.

The child remained very ill all the afternoon. The respirations continued to be rapid and shallow.

At 7.30 p.m., temp. was 103.2, reduced to 102.6 by three grains of sulphate of quinine.

At 11.15 p.m. the child suddenly stopped breathing, its gaze became fixed, and it was quite motionless. The nurse thought that it was dead, but this attack only lasted for about one minute, when it resumed breathing. The respirations were 60 per minute, and the pulse was 136 per minute. She has hardly passed any urine since admission in the afternoon, and as the little she has passed runs into the napkins, no examination can be made.

18th.—Morning temperature 102.6, pulse 120, respiration 60. Bowels open twice since admission. There is no urinous smell about the body. Has passed a little water into the napkin. Child is very weak and breathing very rapidly. Râles all over the chest both in front and behind.

11 a.m.—While the chest was being examined she was seized with a violent convulsion. Both sides of the face were equally affected. The feet and legs twitched slightly at first, but the twitchings afterwards became more violent. The eyes rolled from side to side, and then became fixed. Pupils equal. Pulse very feeble. Given a drachm of brandy which was easily swallowed. This attack lasted about ten minutes. Afterwards the patient lay quietly on her back with eyes open and fixed. Respirations quick and irregular.

1.30 p.m.—Child had another convulsive attack. Both sides of the face were equally affected. The eyes were fixed and staring. Pupils equal, not much dilated. The fingers were flexed across the palms of the hands; the arms twitched very violently; the legs only moved feebly. The head was jerked from side to side. The spasms were distinctly clonic, and very rapid, being over 100 per minute. This lasted for about 15 minutes, the spasms then became weaker and weaker and the child died.

19th.—Autopsy made 24 hours after death. Body well nourished. Post-mortem congestion on the back and shoulders. Rigor mortis well marked. Fingers flexed across

the palm. Feet and legs cedematous. No urinous smell about the body.

Brain.—The sinuses of the dura mater full of dark fluid blood. No sign of any thrombosis. The meninges generally were congested. No lymph or loss of polish of the surface. No sign of any tubercle. The brain itself weighed 38 ounces, and was healthy. Ventricles did not contain any excess of fluid. Tympanic cavities examined by removing a piece of petrous bone. The right tympanic cavity contained mucopurulent material, the left was empty. No caries of the temporal bone.

Chest.—On opening the chest the pleural cavities were found to contain some thickish fluid which smelt strongly of urine. There was a good deal more in the right side than in the left. On this side there were some pleuritic adhesions of recent date. Right lung consolidated at the base. Left lung much congested, no consolidation. No tubercle in pleura or lungs. Larynx and trachea healthy.

Heart.—Weight, 4½ ounces. Valves and tissue healthy. No pericarditis.

There was a small quantity of fluid in the abdominal cavity. No peritonitis. Mesenteric glands not enlarged.

Liver.—Weight, 20 ounces; congested.

Spleen.—Weight, 2½ ounces; rather soft.

Supra-renal capsules healthy.

Urinary system.—Kidneys weighed 4½ ounces together. The capsules stripped off readily. Both organs were congested; the pyramids in particular being of a deep red colour. They smelt strongly of urine. The ureters were healthy and undilated. Bladder empty and healthy. Urethra healthy. No mechanical cause for the suppression of urine could be found.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

A MEETING of the Surgical Section was held in the Royal College of Surgeons, December 7th. Mr. WHEELER, President, in the chair.

LIVING SPECIMENS.

Mr. Stokes, case of excision of the knee-joint for caries in a patient, æt. 36. Mr. Benson, case showing appearances of Jequirity ophthalmia. Mr. Barton, case of double tibial osteotomy. Mr. Lambert H. Ormsby, case of osteotomy for genu valgum.

SPECIMENS EXHIBITED BY CARD.

Messrs. Thornley Stoker, Hayes, Stokes, Lambert H. Ormsby, and Dr. M'Ardle exhibited specimens by card.

REMOVAL OF NASO-PHARYNGEAL TUMOURS.

MR. THORNLEY STOKER read a paper on the removal of naso-pharyngeal tumours. He dealt only with those growths with broad bases of attachment which are properly called tumours as distinguished from pedunculated growths or polypi, and the essential character of which is that, while lying in the naso-pharyngeal cavity and invading other situations they primarily spring from the base of the skull. He detailed two cases in which he had operated successfully, one in 1874, and the other two years ago. In the former case the tumour was fibrous and was taken away through the anterior nasal opening, access being gained to the fossa by making an incision along the side of the nose and enlarging the long opening by removing the nasal edge of the superior maxilla with a forceps. In the second case the tumour was a mixture of the cartilaginous sarcomatous and myxomatous forms. It was of large size, had produced "frog-face," impaired the sight of one eye and ear, and injured the sense of smell. It was also removed by an anterior operation. The nose was divided along its dorsum, its halves turned aside, and the tumour removed by scooping and scraping. It involved the long roof of the nose and pharynx, and three upper cervical bodies, large portions of which had to be taken away with the disease. The patient made a most unexpected recovery and is now in good health. His eyes have approximated to each other, and his hearing is completely, and his sight and smell partly, restored. Mr. Stoker referred to the principal operations which had been performed in the removal of these growths, but stated that his own observation of naso-pharyngeal tumours led him to

the belief that, in the great majority of cases, such heroic measures as operations through the palate by the removal of the superior maxilla or by displacement of it, are unnecessary, and that the disease can generally be attacked and taken away through more limited openings than these operations afford. For coming to this conclusion he had two chief reasons, first, that the growth of the tumour has by the time operation is demanded generally separated the superior maxilla to a considerable extent, so that as the surgeon cuts away the disease he finds his fingers in a cavity where he has room enough for action and exploration, and secondly, that the rough kind of scooping, gouging, or cutting, which is the most efficient means of attacking these tumours when the surgeon proceeds to remove them, does not require much space for its exercise. He did not wish to be understood as denying the necessity of the more formidable operations in some cases. What he sought to convey was, that cases which, to all appearances, require these extreme measures may be radically dealt with by minor means. He did not think a surgeon could even say with certainty what steps he might have to take when beginning to operate, and should, therefore, commence with such a measure as one of those detailed, and alter his hand if he found it insufficient. Photographs both before and after operation were shown of the case in which the nose had been divided along the dorsum, an operation in some respects different from any procedure previously adopted and free from the objection of producing deformity.

Mr. THOMSON, in opening the discussion, said he was present at the operations, and he could bear out thoroughly what Mr. Stoker had said as to the gravity of them. Undoubtedly Mr. Stoker had been extremely fortunate in not having had any return of the tumour in those cases. He had himself had under observation a case which had been under the care of Dr. Robert McDonnell a couple of years ago. A boy, named Richardson, who had come from Limerick, was suffering from naso-pharyngeal tumour, and from his description it appeared that Dr. McDonnell had removed the tumour through the mouth with a snare. When the boy came to him in January last the left side of the nose was filled with a large tumour which could be felt projecting into the pharynx behind. Having failed to get it away by snaring, he determined on a more severe procedure. He slit up the side of the nose, dividing the nasal bones with a forceps, and he was then able, by passing one finger into the mouth through the pharynx, and the other through the nares, to get at the fragment of the tumour. It was attached to the septum of the roof of the nasal cavity. The attachments to the roof of the nose being slight he was able to break them down and remove the tumour in one mass. In three weeks afterwards the boy went away well. Last month, however, he returned, the tumour having recurred, and it presented over the antrum. From the previous history and the fact that he had taken the tumour out of the antrum on the former occasion and that it was fixed as it lay, he was under the impression that it had grown again in the antrum, and, forcing its way through the anterior wall, had made its exit. Being of opinion that it was necessary to remove the upper jaw, casts were made for the purpose. But when he reflected the cheek he found it had not come through the wall, but that it lay on the wall. It passed backwards along the side of the superior maxilla, and escaped through the pterygo maxillary fossa, terminating in the position described. He was able to pass his finger into the nose, and pulling upon it he found it had an attachment on the external wall of the nose, the left side. There was nothing to justify the removal of the superior maxilla. Accordingly he wrenched the tumour out of its place, and he could feel the pedicle giving way. The tumour was about the size of his two fingers placed together. It was a single long tumour similar to the one previously removed. The boy had since gone to the country. He mentioned the case to show the virulence of those tumours springing from the naso-pharyngeal parts, and the hopelessness attending the apparently radical operation.

Dr. ROBERT McDONNELL stated that although he had removed several tumours of the kind he had not been so fortunate as Mr. Stokes in their non-return. At the same time some of them had returned only after long intervals. In the case of a national school mistress from the West the tumour came through the hard palate. It was gouged away, a large cavity being made through which the finger could pass into the nostril, and the rest of the tumour was taken through the mouth. About six years elapsed before the tumour recurred. The case detailed by Mr. Thompson was a remarkable one. The boy had come to himself i

Steevens' Hospital several years ago suffering from a large tumour which pressed forward through the soft palate. When that was drawn forward a roundish mass presented itself which was most inviting for slipping a noose round. He had tried to snare the tumour, but without success, until Dr. Cruise assisted him in producing an instrument with which to slip the noose backwards. Having snared the tumour a large piece came away, and it was obvious the noose went through the substance of the tumour instead of around the base. The effect was, however, to lessen the bulk and improve the condition of the patient; so that he went home. After six or eight months he reappeared with a tumour of very large size which interfered with speech and swallowing and rendered respiration through either nostril very difficult. His snoring at night was so peculiar that it disturbed all the patients in the ward. With his finger he (Dr. McDonnell) could feel what seemed to be the base and pedicle of the tumour growing from the same situation somewhat as described in Mr. Stokes's case, namely, from the under part of the junction of the sphenoid with the occipital bone. He was able positively with the finger of the left hand thrust into the mouth to feel the attachment. He had determined trying to remove the tumour by putting his finger in and using a gouging instrument passed into the nostril. He removed a piece that surprised him, being very little smaller than an ink-bottle. It came with his hand from the mouth. The operation was a most formidable one. The blood was gushing from the mouth and nostrils. When the tumour was taken out the large mass of sponge it took to fill the cavity amazed him. It controlled the hæmorrhage and the boy made a good recovery. About that time last year he again applied for admission to Steevens' Hospital; but he (Dr. McDonnell) had been himself obliged to go away, and then the boy fell into Mr. Thomson's hands. He had exhibited the tumour at the Biological Club. It was identical in structure with that described by Mr. Stokes, and belonged no doubt to the group of sarcomata, but was of that class in which the connective tissue elements sustained cartilage cells verging towards the condition called myxoma.

The PRESIDENT said he had had several cases of nasopharyngeal tumour under his care, including one very similar to that which had just been mentioned. The tumour had been removed previously, and he was consulted upon its return. It occupied the floor of the nose and the antrum. He removed the upper jaw which he exhibited at the Surgical Society some years ago. There had been no return of the disease.

Mr. THORNLEY STOKER did not reply.

Mr. STOKES brought under notice the particulars of a
CASE OF GUNSHOT INJURY WITH UNUSUAL THORACIC
COMPLICATIONS,
which will be found on page 19.

Mr. THORNLEY STOKER said Mr. Stokes's most interesting paper was bristling with paradoxes, a great number of which seemed to him incapable of explanation, although he had himself carefully watched the case. On the evening of the man's admission into hospital the bubbling or gurgling sound was a most remarkable phenomenon, the like of which he had not seen approached in any case before, and he could find no better simile than that it resembled the breaking of gigantic bubbles audible at a distance of upwards of ten feet. The knowledge given by the autopsy bore out his opinion of the cause of the sound. He had attributed it to the rough admixture of air and fluid in the immediate vicinity of the heart, whose impulse imparted the motions, for the pleural sac contained both blood and air. The sounds were synchronous with the action of the heart. He was inclined to believe that the pericardium was wounded, but in that he was wrong, the air was about the pericardium, and the sound was due to the churning together of the blood and air produced by the excited action of the heart.

Dr. Cox detailed two cases of pistol wounds of the thorax. One occurred on the night of the 12th July some years ago in county Sligo. A young fellow was out at night sitting with one or two others on a stile, when a shot was fired by one of a party of men who were proceeding home, and the bullet entered about an inch below the left nipple. In this case the probe passed in straight, but the foreign body could not be detected. There was no hæmoptysis, dyspnoea, pain, or apparent imminent danger. Below the scapula on

the same side he detected a slight amount of dullness, and he formed the opinion that the bullet had glanced off the rib and had lodged in that position. Shortly afterwards symptoms of pneumonia supervened, from which, however, the patient recovered, and an abscess formed in the situation where the dullness had been originally detected. On the abscess being opened the bullet came out. In a second case a bullet passed into the thorax fracturing the clavicle. In this the bullet was not extracted, but the patient made an excellent recovery.

Dr. BEATTY suggested that portion of the lung which remained floated forwards, and, being relaxed, produced tympanic sound. In ordinary cases tympanic sound was heard. He asked what was the condition of the lung, or was this sign present?

Mr. STOKES said the injured lung was perfectly collapsed.

Dr. H. KENNEDY said when pleural effusion existed the sound was tympanic, not from the state of the lung, but because of air in the pleura. When the position of the patient was altered, so was the air. In reference to the comparatively sudden death when pleural effusion existed—which was much more common formerly than now—the patient's life was frequently lost by the comparatively sound lung getting affected. The duty thrown upon it was so great it resented the increase by a sort of passive congestion, which rapidly took place, and was a most unfavourable sign. Where paracentesis was now so rapidly done, such an accident could be averted. As to the sounds over the heart, it was remarkable what sounds were obtained when the pleura alone was engaged, the slightest friction modifying or developing them to a very great extent. The late Dr. Stokes had dwelt on the fact of eliciting sounds of this sort by pressure, the stethoscope being applied, and the hand of a second party used to press lightly on either side. In the case under discussion the heart's action gave rise to the friction sounds that led Mr. Stokes to think the pericardium was engaged.

Dr. BENNETT said he had had the good fortune to see the case during its apparently favourable course, when it was supposed it would end in recovery, and when the physical sign Drs. Kennedy and Beatty had discussed was present. The tympany on altering the position of the patient gave him a very clear idea that there was a small quantity of air in the pleura which rose to the top, ascending as the position was changed. Another point of great interest was that it was clearly established by the post-mortem examination that there was an extensive wound of the lung, and yet there was no hæmoptysis. It was recorded by Fraser, in his Surgery of the Crimean War, that the presence of hæmoptysis was of great value as an absolute diagnostic sign, but that the opposite was not to be inferred. A very extensive wound of the lung might exist without any hæmoptysis.

The PRESIDENT mentioned that Surgeon-General Longmore and Inspector-General Mounatt had drawn attention to the dangers that arose when missiles carried before them any portion of the ribs or spicula of bone. There were cases in which bullets had been lodged in the substances of the heart, and there were no symptoms at all, and bullets had been found in the pericardium.

Dr. LENTAIGNE thought they ought not to be deterred from paracentesis by fear of death during the operation. In a great many cases the result might be satisfactory. At the Medical Section he had exhibited a patient whose mammary artery had been wounded, and on whom he performed paracentesis three times. On the first occasion he removed five pints of almost pure blood from the pleural cavity, and just before the operation the patient seemed to be moribund. The same thing happened on two subsequent occasions. The man fully recovered, yet the cavity refilled. In the end he performed the radical operation, incising with a knife and putting in a drainage-tube. The case turned into one of empyema.

Mr. STOKES, in reply, said he was not quite satisfied with the explanation given by Drs. Kennedy, Bennett and Beatty of the phenomenon. There were no sounds which would indicate a free air in the pleura, and the position of the patient was changed owing to restlessness. Assuming free air was there, it was remarkable, if Dr. Bennett's view was correct, that the air should always mount up in a certain position to exactly the same spot. A small area, two inches in diameter, situate at the base of the heart, and that it should appear in no other portion of the chest. The explanation of Dr. Kennedy and Dr. Beatty would be adequate,

if there was evidence of free air in the pleura, but there was not. He was himself aware of the fact of several cases of gunshot wounds being recorded where the lung was injured, and there was an absence of hæmoptysis, but he could not explain the phenomena witnessed in the case he had now recorded. He did not perform the second operation of paracentesis, the lung being completely collapsed, and the patient would not be sensibly relieved by the withdrawal of the fluid. The opposite lung was completely choked by catarrhal secretion, and therefore, he did not think there would be anything gained by subjecting the patient to another paracentesis.

The Section then adjourned.

LIVERPOOL MEDICAL INSTITUTION.

The Sixth ordinary meeting of the session was held on Thursday, Dec. 20th 1883,

Mr. T. SHADFORD WALKER, President, in the Chair.

Dr. HOWIX exhibited Duke's axis traction forceps with belt for extra traction.

Dr. HAYWARD showed a curious Malformation of the Heart in which the foramen ovale was closed. A large opening existing, however, between the two ventricles, capable of admitting two fingers. The aorta was much enlarged, whilst the pulmonary artery was exceedingly small.

Mr. RICHARD WILLIAMS showed a case of Primary Syphilitic Sore of the Conjunctiva. The patient was a girl, æt. 18, who presented herself at the Eye and Ear Infirmary two weeks ago, with the right eye red and painful. It had then been bad about a month. She had been engaged in nursing a child that died with an eruption on its feet and buttocks, and anuffles. The ulcer which was indurated was situated in the inner angle of the right eye. The pre-auricular gland was indurated. Up to the present, no sore throat or eruption has appeared, but the hair was falling off. The speaker mentioned that Snell, of Sheffield, had reported a similar case.

The PRESIDENT remarked that such cases were very rare. He had seen but two of the kind, and an account was given of another at the last meeting of the Ophthalmological Society of Great Britain.

Mr. EDGAR BROWNE said that the case shown by Mr. Williams was one of primary inoculation of the conjunctiva. He related a case that had been under his care in a man, in which the mode in which the inoculation took place was demonstrated with sufficient clearness.

Dr. RAWDON then gave the history of a case (with specimen) in which

CYSTOTOMY FOR THE RELIEF OF VESICAL IRRITATION

was performed. The patient was a boy, æt. 7, who was admitted into the Children's Infirmary on account of painful chronic cystitis of four months' duration. No cause for the cystitis could be made out with certainty, there was no phimosis, but the urethral orifice was small. Cystotomy was performed on May 9th, the operation being followed by relief of all the symptoms. The urine was, however, pale and deficient in urea and other urinary constituents. After a time the patient went out but returned on Oct. 9th with a large lumbar abscess. This was opened antiseptically. On re-opening this, after premature closure, the cavity was thoroughly explored when a large quantity of pus was discharged from the kidney. The case ended fatally, with symptoms of peritonitis. On post-mortem examination, the left kidney was found hypertrophied, the right was tubercular, and was the seat of a ragged abscess cavity. He was of opinion that the disease may have travelled upwards from the bladder, and that the bladder affection was caused primarily by the contracted condition of the urethral orifice.

Mr. REGINALD HARRISON's opinion was favourable to the operation (of cystotomy) in cases in which there was much annoyance. He had performed it a good many times, and the more he saw of it the more he could recommend it as it afforded a very large amount of relief.

Mr. F. T. PAUL then read a

NOTE ON THE TREATMENT OF COMPOUND FRACTURES,

and showed a form of splint devised by himself that was useful for these and allied cases. The speaker alluded to the difficulty there was in fixing the bones in cases of compound fracture as the splints had to be taken off to permit of the wound being dressed, when, the bone got disturbed.

To obviate this difficulty he had, whilst house surgeon at the Royal Infirmary, devised a form of splint that permitted dressing of the wound without necessitating removal of the splint. The splint consisted of a band of hoop iron, about 1 inch in width and covered by a smooth sheathing of india-rubber. The form of the leg and foot was first accurately taken with a piece of lead. After which the splint was bent so as to have curves exactly similar to those of the lead pattern. The splint was then applied and fastened on by plaster of Paris bandages above and below the point of fracture, and the dressings could then be changed without disturbance of the splint. He considered it a matter of importance however, that the ends of the bones should be wired together, and the wound cavity thoroughly drained. The same form of splint was also of service in ankle-joint disease in children, in which case the paraffin bandage was useful in place of the plaster of Paris as it was impervious to moisture.

Mr. BANKS said that he had used Mr. Paul's splint for the last five years in ankle joint cases with opening at the side and considered that there was no splint like it. He had used it also with advantage in resection of the humerus. He complimented Mr. Paul on his most useful invention.

Mr. PAUL, in reply, said that the splint could be procured from Mr. Critchley in any lengths at tenpence per foot.

Mr. G. G. HAMILTON then gave particulars of

FOURTEEN CASES OF OPERATION FOR RADICAL CURE OF INGUINAL HERNIA

treated at the Northern Hospital. All the cases were without complications. In two the rings alone were stitched—one cure and one failure. In ten the rings were stitched and the sac tied—nine cures and one failure. The two remaining cases were operated on so recently (six and four months ago respectively) that the result was at present uncertain. As regards the ages of the patients one was under 20, three between 20 and 30, three between 30 and 40, three between 40 and 50, two between 50 and 60, and one 60. The length of time that had elapsed since the operation was from twenty-seven months to four, the average being sixteen and one-third months. Mr. Hamilton stated that Lister's most recent method of dressing in these operations was to powder the region around the wound with iodoform and apply salicylic cotton wool after having placed next the wound two or three layers of wet gauze. As to the method of performing the operation his own opinion was that the sac should be removed and the parts of the ring brought together. Experiments made by himself showed that sulphurous chromic acid gut and fishing gut were the two materials that offered the most resistance to purulent fluids, and as the former of these was very easy to tie with he thought it the most suitable material to employ.

Dr. ALEXANDER said he had operated thirty or forty times and also in cases of irriducible hernia. In the latter class of cases his plan was to open the sac, and release the intestine and omentum. In the ordinary class he tied the sac with unchromicised catgut and stitched the pillars of the ring except in the case of children when stitching of the pillars was unnecessary. He rather preferred that the wound should heal by granulation than by first intention.

Mr. BANKS was of opinion that the sac should be dissected out and the pillars brought together with silver wire. He rather doubted whether there was such a thing as radical cure of hernia and thought it advisable that the patient should wear a light truss after the operation. The operation in his opinion should not be undertaken except life was a burden or the patient was incapacitated from following his employment. No cases were so favourable for operation as those caused by undescended testicle as in them there was no cord left in the canal predisposing to a return of the hernial protrusion.

Mr. RUSHTON PARKER was not quite certain that stitching of the pillars of the ring was necessary in ordinary cases. There were cases in which it should be done. He then pointed out that Mr. Hamilton's experiments were not conclusive as to the suitability of the suture material he recommended. The desirable material was one that in due time should be absorbed by healthy structures and not one that should remain long undissolved in a purulent fluid.

The President and Council of the Harveian Society of London have issued cards for a *conversazione* on the evening of January 17th.

PROFESSOR VIRCHOW ON THE INFECTIOUSNESS OF TUBERCULOSIS.

AT the last meeting of the Berlin Medical Society a debate on this important subject took place which was joined in by the *élite* of the medical faculty in Berlin.

Professor Virchow, who has always doubted whether much was to be gained (in the direction of acquiring immunity against tuberculosis by inoculation with a weakened virus, as in the case of splenic fever) from the numerous experiences in earlier investigations, delivered himself of the following *impromptu* speech, which we translate from the *Deut. Med. Zeit.* for the benefit of our readers :—

He said he was not of opinion that the tubercle bacillus had infectious properties in the strict sense of the term. We then reached the difficulty that the terminology did not meet the case. The expression "infection" had, properly speaking, the sense of grouping together a series of processes which agreed in this, that they had as a basis a power of reproduction and that they were dyscratic and affected the whole body, not simply that the material in question came direct to a spot, but that it infected the body, and of which it was assumed that the substances were of a chemical nature. Since fungi had been introduced, and all fungi had been considered infectious, there had been a certain amount of difficulty as to whether, for example, thrush and scabies were infectious processes. The difficulty had arisen from infection and contagion having been mixed up together, things that, according to the speaker's view, were different. When a man asked himself what attitude he should assume in regard to these parasitic diseases in which the small fungi played a principal part he must decide to recognise two principal categories which, although they might be similar in their larger features, were quite distinct as regarded particulars. The one category was best represented by that form of disease which could be produced by the artificial introduction of *aspergillus* into the body, a form which in birds was met with tolerably extensively, and which in geese, for example, caused great devastation. Now, we knew by experiments that had been made extensively, that we met with two kinds : we could see at the point of inoculation that the *aspergilli* grew, and further, that the fungus spread, and appeared in other organs as a metastatic process. Nevertheless, the *aspergillus*, even when it caused these metastases, did not cause any dyscrasia, and there was no ground whatever for the assumption that it was the cause of the specific injury that exercised such a baneful influence over the whole body. If we assumed that the fungus excreted a poison, the *aspergillus* did not cause the impression that it also excreted a poison and acted by reason of it, but it caused its effect on the spot where it was, and carried farther it acted also on other points of the tissues, but they always remained particular spots and we never had a general toxic infection of the whole body. In regard to tubercle, the speaker noted that long before the bacillus was thought of only a single case had been brought forward in which something like a typhoid appearance was manifested, namely, miliary tuberculosis. As regarded the rest, no one supposed that a specific poison had been present along with the local process and that a kind of toxic infection was associated with it, but it had been simply held that a tendency existed to set up new local processes in other places. Thus in the case of pyæmia, for example, that which the embolus caused within the body and that which the other injurious influences attaching to it caused, were very different. We must now make use of our experiences and not believe that all our knowledge up to the present was useless. On the contrary, it had now for the

first time its justification. So long as the fact could not be proved that the bacillus of tuberculosis had such a toxic action we should have every ground for suspecting that it acted where it was, but not upon other regions, and that when, for example, we took the blood of such an infected animal after the first invasion had passed by we could have no expectation that the blood would act injuriously.

On the other hand, we must recognise the enormous difference there is in the other group of diseases where undoubtedly an injurious substance was propagated, as, for example, in the case of splenic fever. At the time when the epidemic of splenic fever broke out amongst animals of the chase in the Grunewald, the speaker made a large number of investigations, and he arrived at the fact that the inoculation of the blood of these animals set up the worst forms of anthrax although not a single bacillus was demonstrable and not a single animal showed such bacilli. Within the last few days a work by Koloff had appeared (a) which confirmed this observation. The writer was more unprejudiced as he had not known of his (Virchow's) investigations. He found that besides the two forms of *bacillus anthracis* a third form must exist in the shape of exceedingly minute granules. Whilst before his (the speaker's) investigations the question was discussed as to whether the fatal course of splenic fever did not depend on the fact that the bacteria were present in the blood in such quantities, that they enclosed the blood corpuscles and thereby prevented the entrance of oxygen and thus brought about actual apnoea, he had succeeded in producing a form of anthrax in which not a single bacterium was demonstrable.

As now the fungi acted neither mechanically nor by their simple presence, nothing remained but the assumption that they were able to exert a particular action upon the material of the body, by virtue of which they called forth toxic products. This form of splenic fungus, and that of the *aspergillus* must be looked upon as two processes standing upon entirely different grounds, and if in processes belonging to the second series a second inoculation must fail, this could not be the case with the first series.

He had convinced himself of the excellence of Pasteur's inoculations when he performed the inoculation experiments in Packisch at the instance of the Minister of Agriculture. They had only one drawback, that vaccination itself had—viz., that from time to time failures were met with which could not be explained. But the failures of Pasteur were all of one kind. He had races of sheep before him which, as it appeared, were more susceptible than those on which he had been accustomed to operate, and the same lymph that he had found suitable in France had simply produced anthrax in some animals, of which they died. Pasteur had shown that a certain kind of fluid could be produced which inoculated, produced a very slight disease which prevented a fresh attack. After the proof it was only necessary to give the protection lymph a form in which it would be certain in its action under any conditions.

He had had the impression that what Baginsky described were circumscribed patches of caseous pneumonia. Instead of the word "tubercle" it would be better to operate with the word "bacillus." The previous speaker had asked if caseous pneumonia were not also tuberculous. It could be called tuberculous, but the speaker saw no ground for calling a process tuberculous, in which no trace of tubercle was present. One should rather ask on the contrary whether tuberculosis and caseous pneumonia were not both the results of the bacillus. It was immensely difficult for many pathologists to accustom

(a) "Ueber die Milzbrandimpfung und die Entwicklung der Milzbrand Bacterien." Prof. Koloff, *Archiv. für Tierheilkunde*, Bd. IX., Hft. 6.

themselves a little to consider things from two different sides, and yet the twofold method—the one from the causal, the other from the essential point of view—was for medicine absolutely necessary. Tubercle was a little nodule. Caseous pneumonia was a comprehensive process. If they both sprang from the bacillus they could both be called bacillar, but they could not both be called tubercular. In relation to this point the speaker mentioned an analogous example. In syphilis we had the same varied forms of manifestation. A formation that appeared as a nodule was called a gumma or syphiloma. But we should not say that this was identical with an erythema syphiliticum, but that things differing in themselves both had their origin in syphilis. No one would look upon a syphilitic bubo and a syphilitic osteosis as identical. Each of them had its own course, and must be considered by itself. We had many more interesting manifestations of the same kind in toxicology. How many-sided, for example, was the action of phosphorus! In the course of accurate study phosphorus necrosis was first met with. Later on we became acquainted through Wegner with the form of phosphorus necrosis of the interior of growing bone. These were two processes that were throughout non-identical. We knew further that phosphorus was the cause of peculiar changes in the liver—acute yellow atrophy. But it was equally true that such processes were met with in which no trace of phosphorus was demonstrable, and we had now accustomed ourselves to recognise several forms of the affection.

From these examples the speaker traced the importance of looking at things from various points of view, and again advised that things that were caused by bacilli should be called "bacillar," and that the word "tubercle" should be employed anatomically for distinct formations. Baginsky in his inquiry had given utterance to a misconception when he said that Laennec, when he established the unity of tuberculosis had derived tubercle proper, and this so-called tubercular-infiltration from the same beginnings. This was decidedly a misconception. Laennec had never considered tuberculosis but phthisis to be one, and had said that phthisis was tubercular. He had then, however, described two kinds of origin—*granulation tuberculeuse*, and *infiltration tuberculeuse*. Finally, in coming to the expression that there was only one phthisis he denied, for example, that there was a syphilitic phthisis. To-day no one made any hesitation about that. He (Virchow) held the belief that there were several kinds of phthisis, and if a man would not accustom himself to this belief, he would never be in a position to understand them. He also believed that it was possible to indicate them terminologically when the cause as such was designated, and the pathological product had its own designation. He should thus believe that what had been described by Baginsky belonged to the inflammatory and not to the tubercular series.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From measles, 2·4 in Birkenhead, and 2·0 in Manchester; from scarlet fever, 2·9 in Leeds, and 2·1 in Newcastle-upon-Tyne; from whooping-cough, 2·3 in Brighton, and 1·1 in Sheffield; and from "fever," 1·4 in Blackburn, and 1·1 in Preston. The 40 deaths from diphtheria included 22 in London, 6 in Glasgow, 3 in Hull, 2 in Liverpool and Edinburgh, and 1 in Dublin. Small-pox caused 4 deaths in Birmingham, 4 in Liverpool, 2 in London, 1 in Glasgow, and 1 in Sunderland.

ENTERIC PARAPLEGIA.

THE wisdom of encumbering the terminology of medicine with new names descriptive of diseased conditions of the body for which hitherto no special appellation has been found, must always be somewhat questionable; but the necessity for such a proceeding is, at any rate in many cases, demonstrable. Within comparatively recent times, not a few "new diseases," so-called, but which would be better described as "unrecognised," have been admitted to our nosology; and inasmuch as they have received the attention and approval of leading authorities in the profession, they presumably deserve all the distinction they enjoy. Multiplication of names is, in fact, an essential part of progress in knowledge aided by discovery; for even in those cases where only amplification of previous experience results from further study of a particular disease, it must often happen that the language of the past is inadequate to depict all that is revealed by present investigations of unhealthy conditions. And thus it becomes imperative to employ for its delineation such terms and phrases as in the association so given to them present the appearance of novelty in nomenclature, and have the force of adding to our already extensive vocabulary of technicalities. Further, one of the best proofs we can have of progress in medicine is assumed to be this very evidence of extended discovery; it being rightly argued

that each newly recognised form of disease reduces the number of possible deviations from a healthy standard with which the practitioner has yet to make acquaintance; and though the rapidity with which this advance is chronicled may seem to be slow as witnessed from year to year, yet when surveyed from afar—and regarded, as well, in the light of all that collateral information as to pathology, treatment, and diagnosis, of which it formed the starting point—it acquires an importance that can hardly be over-estimated.

With such reflections to influence opinion it is quite possible to consider fairly and leniently every new demand in respect to laying a fresh burden on the memory for names. Whencesoever this desire emanates it receives a consideration proportionate to its merit; and in those cases where it can be reasonably shown that new names are necessary to denominate special conditions, there is little objection raised against them. It may, however, be open to question whether Dr. Roberts Bartholow is strictly justified in making the attempt to add to the list of forms of paraplegia one to be described as “enteric,” though the observations on which he grounds the claim are of the most interesting character, and are presented with a clearness and precision that leave nothing to be desired. Dr. Bartholow communicated his views to the College of Physicians of Philadelphia at a meeting of that body held on November 7th last, under the title of “enteric paraplegia.” This term, he said, was intended to express his conception of a spinal paralysis produced by an intestinal disorder; and the condition was illustrated by narration of several cases of the kind referred to, and of which the following may be quoted as an example:—The patient was about sixty years old, and had for a year past been troubled with intestinal indigestion attended by colicky pains, flatulence, and irregular action of the bowels. In addition to these symptoms, a gradually increasing inertness, with diminution of power, had come on in the lower extremities, and this last condition it was which led the patient to consult Dr. Bartholow. Although in this particular case—which, by the way, continued under observation at the time of writing the paper—sensitivity and locomotion had not been, at the date, much affected, still in other examples cited both tactile and heat sensitivity were much impaired, and the power of walking very materially decreased. All these cases are taken by Dr. Bartholow to be instances of paralysis induced through the intestinal system, and by reflex action on the spinal cord as a result of irritation of the nerves distributed to the alimentary canal. He makes two postulatory statements to the effect (1) That there is a reflex paraplegia due to a functional disturbance of the intestine—enteric paraplegia; (2) That there is a paraplegia having its initial seat in the end organs of the nerves distributed to the mucous membrane, thence ascending to the cords by a progressive neuritis.

It is, of course, on the second of these two propositions that the greatest amount of interest centres; but it must also be admitted that the demonstration of it is based on analogy only. It has been shown that the spinal cord may become diseased in cases of chronic

dysentery, pyelitis and vesical catarrh; and an intramuscular neuritis may very conceivably spread upwards until the whole length of nerve intervening between the intestine and the spinal cord becomes subject to degenerative changes. Thenceforward the condition of the immediately affected part must remain stationary; but to what extent the lesion induced in the cord itself will suffice for the production of paraplegia is not so clearly or sufficiently shown as could be desired. Local anæmia in the cord is an important factor in this connection, as has been shown by several observers; and Dr. Bartholow is careful to indicate the influence to be attributed to the condition; while, as determining the degree and extent of the changes set up, he insists on the necessity for considering the nature of the initial alterations. Simple reflex paraplegia is a mainly functional affection, and may be recovered from on the removal of the exciting cause. This in the case of intestinal indigestion is probably the irritation of the collected food on the peripheral nerves, together with stretching from contained gas; from such irritation, stimulation of the vaso-motor centre results, followed by general contraction of arterioles, and thus spinal anæmia is set up. In the more severe and permanent form of the disease the effects are much more serious, depending, as shown, on intrinsic changes in the nervous system.

Dr. Bartholow thus explains how intestinal or renal lesions may in one case produce a merely reflex disturbance, and in another set up an ascending neuritis. A degree of peripheral irritation not too great will merely stimulate the vaso-motor centres, and cause anæmia of the cord by tonic contraction of its vessels; but when the lesions of the mucous membrane are of a destructive kind, depression of the trophic centres, as well as of the vaso-motor, ensues. That there is a neuropathic type of constitution, in which the nerve tissues are peculiarly prone to take on morbid changes, is an indisputable fact. When the two influences coincide, the result is not doubtful.”

It is not improbable that the observations of other practitioners may lend more or less support to those of Dr. Bartholow. They are, at any rate, worthy of being well considered and widely known; and though there may not be many willing to go the length of identifying with him all “enteric” paraplegia, still his conclusions will be received with the respect they deserve from the eminence of their author.

THE LEGAL ASPECT OF THE PROPOSED IRISH CONJOINT EXAMINATION.

THE proposal to compel all licentiates of the Irish College of Surgeons to pass through the College of Physicians (or some other medical licensing body approved by that College) has been, as yet, discussed only as to its expediency, but on further examination of it, we discover that any such abandonment of the separate licensing powers of the College would be totally illegal in the present condition of its Charters. The letters patent under which the College is administered do not, indeed, permit the Council to refuse the diploma

of the College to any person whatsoever so long as the applicant has complied with the legitimate requirements of the Council, and satisfactorily answered the necessary examination, and so far does the Charter carry this perfect freedom of entry to the College that we find no provision to enable the Council to refuse the diploma to a person even of the worst reputation if he had satisfied the necessary educational and examinational requisites. Clause 19 of the Supplemental Charter of the College says:—

"We do hereby, for us, our heirs, and successors, further ordain and appoint that the examiners of said college, or so many of them as may hereafter be declared necessary to constitute a court . . . shall from time to time upon request made to the President, or in his absence to the Vice-President, or any of the Council of the said College, examine in such form and manner, and on such subjects as the Council may, from time to time, direct and prescribe, *every person who shall be desirous of obtaining the certificate or letters testimonial of the said College . . . and who shall have duly observed and fulfilled the rules, regulations, conditions, and ordinances . . . contained in the bye laws . . . and in case the said examiners shall be satisfied with the result of such examination, and shall certify to the said Council to the effect aforesaid, then in such case the said Council shall give to each person so examined . . . such certificate or letters testimonial of his qualification to practise.*"

Thus it is evident that the Council has no right whatever to require a candidate to take any other diploma, or to pass any other examination than that of the College itself, and that the student would—in spite of all regulations made to compel him to take the conjoint diploma—be entitled to demand examination for the separate L.R.C.S.I., and to insist on obtaining the diploma if he passed.

But another legal difficulty presents itself in the way of this conjoint scheme. It proposes that the conjointly examined candidate shall be granted a complete qualification in medicine, surgery, and midwifery, and we are told that the beauty of the arrangement consists in the symmetry of this diploma. But it appears that the Irish College of Surgeons can grant no such diploma in midwifery upon an examination held previous to the grant of the L.R.C.S.I.

The 19th section of the same Charter says—

"And we do hereby further ordain . . . that the examiners of the said College . . . shall . . . from time to time . . . examine in such form and manner and on such subjects as the Council may . . . direct and prescribe, such persons as may so require it, *being Fellows or Licentiates of the College, touching their ability, &c. . . in midwifery, and in case the said examiners shall be satisfied of the result of such examination . . . the said Council shall grant such person such certificate of his qualification to practise midwifery, &c., &c.*"

It is here set down that the licentiate in midwifery must have been submitted to a separate examination in this subject after he became a licentiate in surgery, and no diploma granted upon an examination held previously would have any validity.

If, therefore, the College proposes to force its licentiates into a conjoint examination it will be compelled to seek another change of Charter, and we do not for a moment believe that the Government will grant a change for such purpose.

Notes on Current Topics.

"Soothing Medication."

AN inquest arising out of a death resulting from administration of a "herbalist's" medicine for "soothing" was concluded last week by Dr. Diplock, at Chelsea. The deceased, a carman's widow, had been under treatment at a dispensary for some months on account of bronchitis, but had latterly ceased to attend this institution, and had invoked the services of a herbalist named Wallace. On December 10th she was supplied by Wallace with a mixture and other articles for immediate use; and with the first of these, directions were given to the effect that one or two spoonfuls formed a dose; but the messenger who fetched the compound was informed that, should the patient even swallow the whole contents of the bottle at once, no harm would result. In the sequel the woman did take about one-half the quantity supplied, and died forty minutes after. On examination of the remaining medicine it was found to contain lobelia seeds and acetic acid in such quantity as to explain the post-mortem appearances presented by the body of the deceased, and which included evident indications of an irritant poison having been taken during life. After Dr. Stevenson, on whose statements the above facts were demonstrated, had concluded his evidence, Mr. Wallace proceeded to justify his conduct on the ground that he had himself taken large quantities of the drug without ill effect; and he expressed regret at the little recognition accorded by the medical profession to so useful a remedy. Dr. Diplock very properly ordered the man to abstain from such utterances in the face of the opinion recorded by Dr. Stevenson; and the jury marked their estimate of the value to be attached to Mr. Wallace's skill in medicine by returning a verdict of manslaughter against him, and he was then duly committed for trial on the charge. At the termination of the first hearing of the case before the magistrate on Saturday last, Wallace was remanded on his own recognisances in £100.

Pre-Connubial Suicide.

THE case of the youth Denton, whose death was inquired into before Mr. Carter at St. Thomas's Hospital on the 31st ult. is one of a kind that possesses considerable medical and psychological interest. An auctioneer's assistant, in comfortable circumstances, he was engaged to be married, and had himself fixed the ceremony for Christmas Day, but instead of presenting himself at church at the appointed time, he swallowed a quantity of carbolic acid in his own lodgings, from the effects of which he died in a few hours. It appeared from the evidence given at the inquest that Denton was not quite steady in his habits, and had been the worse of drink several times recently, but his intemperance had not gone to such an extent as to disorder his mind, and was even unsuspected by the young woman to whom he was engaged, and it could not therefore have been the cause of his suicide, which may with much more probability be ascribed to the profound emotional disturbance which so often visits those on the verge of matrimony. No one, unless of callous and obdurate nature, can enter upon the married state with its responsibilities and

possibilities and altered habits of life without some agitation and misgivings, and these in the case of men of peculiarly sensitive and diffident temperament, or with an inherited tendency to insanity or nervous disease, mount sometimes into morbid excitement, delusions, or transient delirium. Every year a considerable number of suicides take place which are to be attributed entirely to pre-connubial anxieties and misapprehensions, which might have been obviated in many instances by a little sound physiological teaching, or by a consultation with a sensible doctor. Post-connubial suicides also arise mostly from ignorance and nervous excitement in men of fine-strung organisation, and they, too, might often be avoided by timely medical advice.

Richard Owen, C.B.

No distinction has ever been more richly merited by its recipient than that with which the veteran keeper of the Natural History Collection will retire from a post in which he has worked with a success that few can hope to imitate. Professor Owen's claims are of a kind that no reward could too extravagantly repay, for in him has British science found for more than half a century a learned and vigorous exponent, and a strong and earnest champion. In every quarter of the civilised world his name is revered and honoured; and friends will congratulate him from all countries on the occasion of his receiving from his Sovereign the highly-prized mark of favour to which he has been gazetted. The rank of C.B. is eminently fitting to the author of "Comparative Anatomy of the Vertebrates;" his whole life has been marked by devotion to the science which early allured him to its study; and by his own bright example of industry and integrity he has done more than any living contemporary of his own to ennoble and popularise the pursuit of natural science for its own sake. A universal wish that he may be spared to enjoy the ease and dignity of repose after his long labours, will be experienced by every one who knows the veteran professor either personally or by reputation.

The Bower and Keates Defence Movement.

THE response given to the appeal made by the committee appointed to collect subscriptions on behalf of the Bower and Keates Defence Fund, has been so speedy and considerable that already the amount required to cover the legal expenses has been more than obtained. An announcement has therefore been made to the effect that the list of subscribers would be closed on the 5th inst.; but the secretaries, Drs. Mahomed and Burnet, will be glad to receive further signatures to the memorial that is being prepared in connection with the case. The result of the movement so far is a most welcome and satisfactory indication of the readiness with which, when duly roused to a sense of the danger which menaces it, the medical profession can be induced to unite in its own defence; and for the vindication of its own honour and dignity when threatened in the persons of its individual members.

PROFESSOR HUXLEY will, it is rumoured, be offered a baronetcy.

The Medical Societies.

THE annual election of officers of several of the medical societies will take place within the present month, and the following nominations have been made at the societies named. In each case an asterisk is placed against names of gentlemen who are proposed for the particular office for the first time.

For the Clinical Society.—President: Sir Andrew Clark, Bart., M.D., LL.D. Vice-Presidents: *J. W. Ogle, M.D.; F. W. Pavy, M.D., F.R.S.; R. Southey, M.D.; John Croft; Arthur E. Durham; *W. Marrant Baker. Treasurer: Christopher Heath. Council: *H. R. Crocker, M.D.; *A. W. Edis, M.D.; *William Ewart, M.B.; Robert Liveing, M.D.; R. J. Lee, M.D.; *Stephen Mackenzie, M.D.; F. A. Mahomed, M.D.; W. M. Ord, M.D.; T. Gilbert Smith, M.D.; Frederick Taylor, M.D.; Arthur E. J. Barker; *Clinton T. Dent; *J. W. Haward; R. C. Lucas; J. H. Morgan; *Henry Morris; H. W. Page; R. W. Parker; *Gifford Ransford; W. J. Walsham. Honorary Secretaries: Sidney Coupland, M.D.; *R. J. Godlee, M.S.

For the Pathological Society.—President: John W. Hulke, F.R.S. Vice-Presidents: William H. Broadbent, M.D.; *William Cayley, M.D.; *George Johnson, M.D., F.R.S.; Samuel Wilks, M.D., F.R.S.; Sir William Bowman, Bart., F.R.S.; John Croft; Arthur E. Durham; *George Lawson. Treasurer: *John Wood, F.R.S. Honorary Secretaries: James F. Goodhart, M.D.; *Henry T. Butlin. Council: Robert Barnes, M.D.; John Curnow, M.D.; Frederick A. Mahomed, M.D.; Joseph F. Payne, M.D.; George V. Poore, M.D.; Frederick T. Roberts, M.D.; *Seymour J. Sharkey, M.B.; Reginald Southey, M.D.; *Francis C. Turner, M.D.; *Samuel West, M.D.; *Arthur E. J. Barker; *Henry H. Clutton; William H. Cripps; Alban H. G. Doran; Alfred P. Gould; Thomas R. Jones, M.D.; John Langton; R. Clement Lucas; *Henry Morris; Edward Nettlehip.

For the Harveian Society.—President: *G. P. Field, Esq. Vice-Presidents: P. Boulton, M.D.; *D. Ferrier, M.D.; *Henry Power, Esq.; *J. H. P. Staples, M.D. Treasurer: Thomas Buzzard, M.D. Honorary Secretaries: J. Ernest Lane, Esq.; *William Ewart, M.D. Council: W. Allen Aldred, M.D.; W. Hickman, M.B.; S. H. Davson, M.D.; W. R. Gowers, M.D.; Charles Vasey, Esq.; James E. Pollock, M.D.; Malcolm Morris, Esq.; *E. Symes Thompson, M.D.; *John Cavafy, M.D.; *Henry E. Juler, Esq.; *Thomas Bryant, Esq.; *A. Dunbar Walker, M.D.

WE had the pleasure of witnessing on Tuesday night last an excellent entertainment which was given to the patients at St. Mary's Hospital, Paddington, in the new accident ward. In addition to the patients who were able to attend, some 300 visitors were admitted by ticket. The entertainment commenced by an "Exhibition of Mrs. Jarley's Waxworks," the figures being represented by young ladies and gentlemen who are interested in the welfare of the hospital. This highly-amusing exhibition was followed by a concert, of which it is needless to remark all who took part in the performance gave very general satisfaction to a very delighted audience.

A Lapeus Lingue.

THE tongue is proverbially an unruly member, but we question whether it is best disciplined by being strapped to a chair. This, however, is the corrective measure which was adopted in the last resort in a case of lingual insubordination by Mr. John James Mansfield, assistant master at the Greencoat School, Whitehall Street. A pupil of Mr. Mansfield's named Arthur Parry being of a garrulous disposition, and having failed after repeated canings, to grasp in its full practical significance the philosophy of silence, was induced to put out his tongue, whereupon it was caught in a strap with a slip knot and made fast by a string to a chair. Instead of being presented with a piece of plate in recognition of his inventive genius device, Mr. Mansfield had to appear at the Thames Police Court to answer a charge of assault. Any complaint, however, which he might have against the blindness and ingratitude of his generation could not extend beyond the mere fact of his being summoned, for the moment that he appeared in the dock he found an appreciative and sympathetic spirit in the presiding magistrate, whose conduct of the case is memorable. His worship began by asking Master Parry, æt. 8, whether he understood the nature of an oath, and on receiving no very satisfactory answer to that somewhat abstruse question, he reprehended his father for bringing up his offsprings in such ignorance, but had the tables turned upon him when the father showed that the child knew very well that it was wrong to tell a lie, and that it was not his knowledge of ethics, but the worthy magistrate's knowledge of juvenile human nature that was at fault. His worship next signalled himself by declaring that if there was a scar on the boy's tongue it must have bled, thus displaying his familiarity with physiology and surgery; and he finally showed his logical acumen by maintaining that to tie a boy's tongue to a chair, was analogous to putting a fool's cap on his head in order to degrade him in the eyes of his fellows. The summons was dismissed. It is sincerely to be hoped that we have not heard the last of this case, as it would be disastrous if the notion should go abroad that schoolmasters may with impunity resort to such inhuman and dangerous practices as that of putting a ligature upon the tongue of any talkative scholar. It may have been that in this case the strap was applied more *pro poeme*, or as a joke than with any cruel intention, but even in this light the act was most reprehensible, and should not have escaped censure. Even regarded as a joke it was a very sorry one, and calculated to have a demoralising effect on all who witnessed it. The next schoolmaster who follows Mr. Mansfield's example might apply his strap in a more determined manner, and certain it is that the tongue might be most seriously damaged and exquisite torture caused without any bleeding taking place. The children of the poor have enough of suffering to endure without gratuitous inflictions of this kind.

THE inaugural meeting of the Hospitals Association will be held, by permission of the Lord Mayor of London, at the Mansion House, on Friday, the 1st February, at 3 o'clock. His Lordship will preside.

Army Medical Service.

IN the Army Medical Department a number of important retirements and promotions will this year take place under clauses of the Royal Warrant. The retirements will be three in number from the Surgeon-General's list—viz., Dr. Alex. Smith, C.B., Principal Medical Officer, Gibraltar, 14th Oct.; Dr. James Lamprey, 15th Oct.; and Mr. Richard Gilborne, Principal Medical Officer at Aldershot, 20th Nov. These retirements may be expected to promote Deputy Surgeons-General A. H. Frazer, Principal Medical Officer at Dublin; John Hendley, C.B., Principal Medical Officer at Allahabad; and H. B. Hazard, C.B., Principal Medical Officer at Umballa. It may be mentioned that Dr. Crawford attains his 60th birthday in March next; but under par. 317 of the Royal Warrant the Director-General of the Army Medical Department who is appointed for a fixed period of seven years is not affected by his attaining the age of 60 years during his tenure of office.

Occurrence of Three Infectious Diseases in the same Individual.

DR. PRIOR, Assistant to the Royal University Polyclinic in Bonn, communicates to the *Deutsche Med. Wochens.*, Aug. 1st, a case in which three different infectious diseases occurred in the same individual in the space of one month. Three children were attended on Nov. 18 for well-marked scarlatina, with a temperature of 104 deg. Fahr., copious eruption, and some difficulty in swallowing. Desquamation began on Nov. 21, and proceeded normally, only one child having slight renal symptoms, until on Dec. 1, the two younger were attacked with rigors, headache, and malaise, and on the following day were covered with a thick eruption of varicella. On Dec. 3, in the absence of the mother, a child from the next room, intercourse with which had been carefully avoided on account of measles, was found playing with the child, and showed signs of measles next day. The first patients were now carefully watched, and on Dec. 13 the temperature was found to be raised, with photophobia and slight coryza; on the 15th the eruption of morbilli appeared. Its course was protracted, and caused some anxiety; but finally the children recovered. The cases show how the two poisons of scarlatina and varicella may be in the organism at the same time, and how measles may be conveyed by a two hours' intercourse in the prodromal stage, while the crusts of varicella are still present, the measles showing itself as soon as ten days later.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 26, Bombay 23, Madras 43, Paris 24, Brussels 23, Amsterdam 29, Rotterdam 22, The Hague 20, Copenhagen 20, Stockholm 22, Christiania 20, St. Petersburg 29, Berlin 24, Hamburg 24, Dresden 26, Breslau 28, Munich 29, Vienna 24, Prague 39, Rome 25, Turin 26, Venice 32, Lisbon 30, New York 23, Brooklyn 20, Philadelphia 19, and Baltimore 20.

The Lisburn Infirmary.

As a commentary upon the exhortation which we uttered recently to the surgeons of county infirmaries in Ireland to make an endeavour to render their hospitals independent of public money, we note that at the Presentment Sessions last week, on application for £500 for the County Infirmary at Lisburn, attention was directed to a resolution passed at the Presentment Sessions held at Ballymoney on the 11th ult. The resolution was to the effect that the County Infirmary as situated at Lisburn had ceased to serve the purposes for which it was intended, and that, if such an institution were necessary, the funds of the county should be applied in connection with the Belfast Royal Hospital. After some discussion, an amendment was proposed that the presentment be reduced to £300, which on being put was lost, and the presentment for £500 was then allowed.

Insectivorous Plants.

In the *Monthly Journal of Science* we find an interesting paper, by Mr. H. M. Busgen, on the "Nutrition of the *Drosera* by means of the Insects which it Catches." To determine how far fly-catching is necessary to the plant, or how far the seizing of the insect is a matter of chance, the author cultivated eighteen young plants in a piece of peat fertilised with a chemical solution. One half of these he fed diligently on aphides, the other half he starved. Having kept them for the winter, he found that in May the fed plants were altogether more robust than the others, and had a greater proportion of leaves. Subsequently, he observed that they produced nearly three times as many blossoms and five times as many seed capsules as the unfed ones, and on drying them afterwards he found that those to which he had given the food were more than three times the weight of the others. By a further series of experiments, he satisfied himself that this luxuriance of growth did not depend on the liquid or soil in which the plants were cultivated, but that, under all fairly equal circumstances, the fed plants thrive much the best.

Cork Workhouse.

At a meeting of the guardians held for the purpose of electing a visiting physician to the workhouse in the vacancy created by the decease of Dr. John Wall, there were three candidates, viz., Drs. T. Gelston Atkins, W. Ashley Cummins, and Magner. At the end of the second poll, Dr. Cummins received 45 votes, and Dr. Magner 30, the former being elected.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 21.9 per 1,000 of their aggregate population. The rates of mortality in the several towns were:—Bradford, Portsmouth 15; Salford, Halifax, 16; Bristol, Huddersfield, Plymouth 17; Leicester, Hull, Birmingham 18; Sunderland, Derby, London, Edinburgh 19; Sheffield, Cardiff 20; Wolverhampton, Nottingham 21; Birkenhead 22; Leeds, Brighton, Bolton 23; Oldham, Liverpool, Glasgow, Preston 24; Blackburn, Manchester, Norwich, Newcastle-on-Tyne 25; Dublin 27.

Infant Mortality in the Manufacturing Districts.

DR. BROWN, in his last report to the Bacup Sanitary Authority, draws attention to an important cause of the high infant mortality in the district of which he is medical officer. Many infants (he says) contract bronchial diseases by being taken from warm beds soon after five o'clock in the morning into a neighbour's house to be nursed during the day while the mothers are at the mill, and fetched back again in the evening. The cold and exposure twice a day are very obnoxious to young children, the power of resistance being very limited. Upon being asked by the Mayor what remedy he proposed, Dr. Brown replied that the mothers should be compelled to stay at home to look after their offspring. His Worship, however, feared this could not be done without Act of Parliament, and so the evil will have to continue till Government takes up the matter.

Microbomania.

THE symptoms and effects of this malady are wittily described by M. Paul Somans in the feuilleton of a recent issue of the *Gazette Médicale de Paris*. He speaks of it in connection with the numerous maladies which have recently been described, such as agoraphobia, claustrophobia, and morphiomania. Microbomania is an affection of adult or middle age, sometimes attacking those in advanced years. It is most frequently observed among educated physicians, those most given to biological research, and almost always ambitious. It is characterised at the *début* by a great desire for notoriety, accompanied by a slight degree of fever and a craving to find certain mobile corpuscles. The desire is soon followed by acts calculated to satisfy the special craving. In the end hallucinations are developed as to the presence of corpuscles in impaludism, measles, scarlatina, even in mumps, and the minute organisms are charged with all the crimes imputable to each pathological individuality. The disease is imitative, and if several individuals under the influence of this form of mania should concentrate their attention on one and the same disease, they are very apt to find widely differing microbes.

Investigations in Endemic Leprosy.

DR. ARNING, lately assistant to Professor Neisser, Breslau, has taken his departure for Honolulu for the purpose of studying the nature of the endemic leprosy of the Sandwich Islands. The German Government has allotted the sum of 6,000 marks for the expenses of the investigation.

THE *Broad Arrow* says that a distinguished member of the Indian Medical Service, who passed first out of Netley, and who recently resigned his commission in disgust, has decided to bring an action for breach of contract against the Indian Government on the ground that his services were obtained under false pretences. Should he gain his case, the example would probably be followed by many other aggrieved medical officers. In any case, the position of the Government will hardly be a dignified one.

The Newcastle Water Supply.

THE annotation in our last issue on the water supply of Newcastle-on-Tyne and its relation to the health of that city has been made the subject of comment by the leading newspapers of the place; and from the statements which have appeared it is clear that the conclusions suggested by a consideration of Dr. Armstrong's report are not borne out by the facts now produced. The principal objection we urged against the supply was derived from the existence of a pumping station on the Tyne for supplementary purposes, but which we learn from the Water Company's secretary, and from our Newcastle contemporaries, is no longer in use. It is clear, therefore, that all danger to the city from such source is avoided; but we must adhere to the opinion that, in view of the mortality with which Newcastle has been lately visited, the most searching inquiry should be made respecting every possible cause of the high death-rate, and it is satisfactory to know that the danger suggested in connection with the water supply is without foundation. We had but one aim in view in the remarks made, that—viz., which is expressed in the motto under which we sail, *salus populi suprema lex*.

THE baronetcy recently mentioned in these columns as about to be conferred on Mr. Bowman was officially gazetted on Friday last. We beg to offer our sincere congratulations to Sir William Bowman, the latest recipient of royal favour.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

INFECTIOUS DISEASES IN EDINBURGH AND THEIR NOTIFICATION.—A report submitted by Dr. Littlejohn to the fortnightly meeting of the Public Health Committee of the Edinburgh Town Council, held Thursday, showed that 92 cases of infectious diseases were at present being treated in the various hospitals in the city, viz.:—City Hospital, 9; Old Infirmary, 58; Sick Children's Hospital, 30. Of 55 cases of death from preventible diseases last month, 25 were due to measles alone. During the bygone year 448 deaths were registered as having been due to preventible causes. There was a marked diminution in the number of fatal cases of typhoid fever, the mortality amounting to 40, as compared with 71 in 1882. On the other hand, there had been a considerably increased mortality from measles—a disease which has been epidemic in the city for some months. The deaths during the year numbered 138, as against 87 in 1882. With regard to the 5,411 notifications by practitioners as to the outbreak of infectious diseases in the city, it may be of interest to know that 2,071 came from the New Town north of Princes Street; 2,571 from the Old Town; and 769 from the southern suburbs south of the Meadows. The intimations concerning scarlatina, which has also been epidemic for some time, numbered 1,817, while notice was given of nearly 8,000 cases of measles. Last month there were recorded 1,005 cases of measles, and 246 of scarlatina. The cases of diphtheria numbered 214; typhoid, 346; and typhus, 50. During December £125 12s. 6d. were paid for the notification of disease in Edinburgh, and during the past year £676 7s. 6d. for the same purpose. When will the ratepayers of Edinburgh wake up to the fact that they

are paying so heavily for so little? We have always maintained that the notification of disease without summary removal to a hospital is useless, and, if we wanted a further support of our contention, Edinburgh is kindly supplying us all that is required. For its 3,000 cases of measles Edinburgh will have to pay £375 in fees, besides other expenses, which might have been saved by a little more energy in isolating the first cases. Many of these cases are notified by students attending the dispensaries, the paper is received, the dispensary credited with the fees, and there the matter ends. Yet it is in the very dens attended to by students that infectious diseases thrive, flourish, and from which they spread.

A YEAR'S MORTALITY IN EDINBURGH.—In the course of the past year 4,275 deaths were recorded in Edinburgh, being equal to 18.22 per 1,000. The average rate for the previous five years was 19.69. The deaths in the New Town numbered 1,335; in the Old Town, 2,433; and in the southern suburbs, 507.

MEDICAL APPOINTMENT.—Dr. Hugh Sinclair, of Bankfoot, Achtergowan, Perthshire, has been appointed by the Parochial Board, and Town Council of Inverary, Medical Officer for the burgh and parish of Inverary, and will enter upon his duties forthwith. We hope his experiences will be of a more pleasant nature than were those of his predecessor. There were nineteen applicants.

THE RECTORIAL ADDRESS AT EDINBURGH UNIVERSITY.—Sir Stafford Northcote, who was in November elected Lord Rector of Edinburgh University, has arranged to deliver his rectorial address to the students on the 30th inst. The right hon. gentleman is expected in Edinburgh on the 29th, and will leave for the South on the 31st of the month.

ROYAL INFIRMARY, GLASGOW.—The annual meeting of the managers with the nurses of the Glasgow Royal Infirmary took place in the Dispensary Hall on the 1st inst. The Lord Provost presided, and the Rev. Dr. Robertson, of Irvine, gave an address. After the meeting toys were distributed to the children in the wards.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 29th ult., was 83, and the death-rate 18 per 1,000. Diseases of the chest accounted for 40 deaths, and zymotic causes for 10, of which 1 was due to diphtheria, 2 to scarlatina, and 6 to measles, the intimations of these diseases for the week being 8, 55, and 220.

GLASGOW DEATH-RATE.—The deaths in Glasgow for the week ending with Saturday, the 29th ult., were at the rate of 24 per 1,000 per annum, as compared with 26 in the preceding week, and 33, 27, and 27 for the corresponding periods of 1882, 1881, and 1880 respectively.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The Council of the Faculty have appointed Dr. D. J. Hamilton, Professor of Pathological Anatomy in the University of Aberdeen, to give the Faculty Lectures for the year. The subject of the course will be, "The Structure and Functions of the Brain in relation to Disease."

"THOUGHT-READING IN EDINBURGH."—During the last week Mr. Stuart Cumberland has, under the "moral support" of Divinity, Law, and Physic, been giving his expositions of so-called "thought-reading" to enormous audiences. The whole proceeding appears to us to be from beginning to end a clever piece of jugglery, and the reason that Divinity, Law, and Physic should lend their moral support to Mr. Stuart Cumberland any more than to the host of clever prestidigitateurs who are now travelling about

the country is not easy to understand. The cabinet trick can be seen everywhere, for Mr. Cumberland is as carefully curtained from view as other jugglers. With regard to the thought-reading performance, we noticed that Mr. Cumberland held his mediums by placing his fingers on the muscles which act on the ring and little fingers—parts of the hand most liable to movement under any marked mental excitement. At a private demonstration we learn that Mr. Masson, a son of Professor Masson's, proved a *bad* medium, for that gentleman, while still thinking of the concealed article, made a point of walking faster where it was concealed, and slower where it was not. All that can be said of the whole affair is that Divinity, Law, and Physic have for once conspired and combined to provide Edinburgh with a clever and amusing practical demonstration of Butler's lines. Doubtless the pleasure is as great to be cheated as to cheat.

THE INSPECTION OF LABOURERS' DWELLINGS BY IRISH POOR-LAW MEDICAL OFFICERS.

THE refusal of the Irish Local Government Board to suggest to Irish boards of guardians the propriety of paying their medical officers for the work done by them under the Labourers' Dwellings Act, and the refusal of the guardians to pay without such suggestion, has compelled the Irish Medical Association to assert at law the legal rights of the medical officers of health. We understand that a writ in the superior courts is about to be issued by the solicitor to the Irish Medical Association against the guardians of a Union in the South of Ireland, to recover the amount of the fees due to the medical officers of health of the Union for the inspections made by their order, and, knowing what we do of the circumstances of the case, and of the law bearing upon it, as already explained to our readers, we do not doubt that a decision will be obtained which will be instructive alike to the guardians throughout Ireland and to the Irish Local Government Board.

COMPULSORY NOTIFICATION OF DISEASE.

THE only expedient of which the average Corporation official seems to be capable when infectious disease presents itself is to lay the doctors under contribution and thus shift his own responsibility on to the shoulders of the profession. We note that in Cork the Town Council's committees are trying this way out of their difficulties, and in connection with an increase of scarlatina in their city, have passed a resolution, which declares:—

"That, with a view to enforcing the 141st section of the Health Act, which gives power to the sanitary authority to compel the removal to hospital of cases of infectious disease . . . the dispensary doctors are asked in every case coming under their notice, in which they consider it necessary to have the patient removed to hospital, to furnish the sanitary authority with certificates such as are prescribed by the Act. . . . On receipt of the certificate the sanitary officer is to be directed to at once send the ambulance-van to the house of the sick person, and *he* is to decide which of the two hospitals the case is a proper one for. In case of a refusal to go the sanitary officer is at once to get a justice's order compelling the removal to the hospital selected by him, and if the order be obstructed or disobeyed, the sanitary officer is to proceed under that section of the Act of Parliament against the persons causing the obstruction."

We are surprised that the Cork Corporation did not impose a fine on the doctors or threaten them with imprison-

ment, which would be the usual corporate way out of a scarlatina epidemic. We can, however, promise them that, if they pursue their determination to imprison everyone who does not choose to go to hospital they will have plenty of concealed disease to deal with. Bumble evidently fails to discern that "force is no remedy."

THE PURCHASE OF POOR-LAW APPOINTMENTS.

THE Listowel Guardians and the Local Government Board are at war upon the election of a medical officer for the workhouse. The Guardians elected a gentleman who, we believe, commended himself to their consideration by the fact that he had bought out the last incumbent. This appointment the Local Government Board refused to sanction, and ordered a new election, to which the Guardians have responded by re-electing the purchaser; and the question of sanction or no sanction is now before the Local Government Board. We hope that they will show their determination not to tolerate the traffic in Poor-law appointments by refusing their approval to the appointment, for the system of election to Poor-law offices in Ireland—strongly influenced as it is, in almost all cases, by politics, personal favour, religion, and every consideration except the fitness of the candidate—would be made, if possible, one degree worse if these appointments were openly put up to auction, as the Listowel Guardians desire that they should be. We look to the Irish Local Government Board to stop this last degradation of their medical service; and, if they evince firmness in dealing with this transaction, we believe that the public, Parliament, and every honest man will say that they have done rightly.

WE understand that the names of Dr. Benjamin G. MacDowel and Dr. W. J. Smyly have been proposed to the College of Physicians of Ireland for election as Fellows of the College at the meeting which will take place in April next. Should these gentlemen be elected, which we do not doubt, it will be necessary for them, in conformity with the rule of the College of Physicians, to resign their Fellowships of the College of Surgeons, and thereby the examinerships held by them in that College will become vacant.

Correspondence.

THE CONJOINT EXAMINATION SCHEME.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with much care your article on the Proposed Conjoint Examination for Ireland in the *Medical Press* of December 19th, also Dr. Barton's letter on the same subject, and your comments thereon in the *Medical Press* of this day's issue, and it seems to me that you have altogether lost sight of the true merits of the case.

Dr. Barton in his letter remarks that notwithstanding the efforts of the Royal College of Surgeons in Ireland to raise the standard of examination, its qualification "remains, and must remain, what the Royal Commission has called a 'half qualification,' the existence of which has been held as a main reason for legislation." This statement involves two propositions: 1st. That the qualification of the College of Surgeons is but a half qualification; 2nd. That the admission of practitioners to registration on half qualification is held as a main reason for legislation.

Both propositions are worthy of observation. 1st. In the matter of giving half qualifications the Irish College of Surgeons is not more to blame than others. They all give but half qualifications, but the greatest defaulter in this respect, and the one whose defaults have given greatest weight to the complaint, has been the College of Surgeons of England. Till recently it examined in nothing but anatomy and surgery, and it was necessary for its members to go elsewhere to be examined in the other branches of medical science. The Irish College

from its foundation took pride in giving a thorough and complete education. It was its boast that its licentiate was *factus ad unguem*, fully and thoroughly educated, but when the Poor-law was introduced into Ireland, our legislators, applying the circumstances of the profession in England to Ireland, ordained that no medical man could hold an appointment under the Poor-law who had not a double qualification. Thus the system of double qualifications was forced on the profession in Ireland, and the College of Surgeons had for a time to relax its efforts to give a complete education. Under the new scheme of examination this has been corrected, and now a very full examination in medicine, surgery, and midwifery is given; but still the diploma is not recognised as a full qualification, nor can any man possessing it alone hold an appointment under the Poor-law.

Dr. Barton's second proposition that the admission of practitioners to registration on half qualifications is held as a main reason for legislation is incontestable. In the Act of 1858, a special clause was introduced (19) to provide for a voluntary co-operation and conjunction between licensing bodies, which has unfortunately been but imperfectly and partially made use of. The Secretary of the late Royal Commission in his appendix to the report, speaking of these half qualifications, says: "That under the Act (1858) these half qualifications enabled a man to get upon the Register, and thereby to appear before the public as a State-guaranteed medical practitioner, although his qualification lay in one only of the two essential branches of practice, and although the purpose of the Act was expressly declared in its preamble to be to enable a distinction to be made between 'qualified and unqualified practitioners,' this was felt to be so serious a defect as in itself to call for further legislation." Again, Mr. Simon writing to the General Medical Council on behalf of the Lord President, on May 14th, 1869, specified as "the most crying evil" the fact that "persons practising on half qualifications are to be counted by thousands in the United Kingdom." The Royal Commissioners themselves say: "Another prominent defect of the present licensing system lies in the fact that nearly all the medical corporations grant diplomas in medicine alone, or in surgery alone. Further, even the diploma of the Royal Colleges of Surgeons of England and Ireland does not imply a knowledge of midwifery. There is no point of medical reform on which there is so general an agreement as that the holding of a medical licence ought to imply a sufficient standard of proficiency in all the three essential branches of medical practice—medicine, surgery, and midwifery."

You, Sir, assert in your comments on his letter, that "Dr. Barton has not succeeded in convincing us that the scheme would serve any good public purpose," but I trust that your readers will see that a scheme calculated to lessen this "most crying evil" will serve a good purpose, and that it is a praiseworthy effort on the part of the Colleges to put a stop to the system whereby "half qualified," more correctly, half educated, men are put forward to the public as state guaranteed practitioners. It is, moreover, but carrying out the traditions and aspirations of the Irish College of Surgeons, that its licentiate should be "*factus ad unguem*," and in making some sacrifice to accomplish this, the College is but fulfilling its duty to itself, to the profession, and, above all, to the public, to supply whose wants it was established, and to promote whose welfare has always been the aim of its existence.

The extent of this sacrifice you estimate at £1,000 or £1,100 a year, but this is altogether illusory, as I shall in a future letter be able to show. In the meantime it is satisfactory to know that the English and Scotch corporations are working in the same direction as ourselves; that the Colleges of Surgeons and Physicians of London have a scheme of conjoint examination prepared, an essential part of which is that they shall cease to grant separate diplomas, or half qualifications; and that the Scotch corporations are improving their scheme, and arranging to give up their separate examinations. So it will no longer be "at the discretion of the student," as you so ardently desire, to perpetuate this "crying evil" of half qualifications.

You say: "An Irish conjoint examination at the discretion of the student and without merging the separate licensing powers of the two Colleges is essentially deserving of encouragement, a compulsory co-partnership which would limit the free choice of the student, and tie up Colleges to the abrogation of their licensing powers is altogether intolerable, unjustified alike by any circumstances which exist, or by any anticipations of the future, futile as a diplomatic expedient,

and ruinous as a commercial speculation," and you do not believe that the Fellows of the Irish College of Surgeons will assent to it. Sir, I have sufficient faith in the Fellows of the Irish College of Surgeons to believe that when they see it will be for the public good, and for the honour and reputation of the College, they will not only assent to it, but demand that it shall be carried out in its entirety, notwithstanding its interference with the "free choice" of ignorant, indolent, ill-advised students, or even the "alienation" of your "thirty-five licentiates," hapless holders of half qualifications.

Yours, &c.,

GEORGE H. KIDD,
Past President of the Royal College of Surgeons, Ireland.

January 2nd, 1884.

[The sum and substance of Dr. Kidd's contention is that the Irish Colleges are imperatively called upon to drive their candidates through a conjoint examination, and to submit themselves to any sacrifice in order to create an Irish "Double Dip," and thus abolish what he calls "the half qualification."

We meet this contention by denying emphatically that there exists between the Irish Colleges (however it may be in England or Scotland) any "system whereby half qualified, or more correctly, half educated, men are put forward to the public as State-guaranteed practitioners," and we feel obliged to characterise such a statement as a libel on the holder of the L.R.C.S.I. and L.K.Q.C.P.I. Dr. Kidd must know, being himself honourably connected with the reformed scheme of education and examination of the Irish College of Surgeons, that the four examinations to which the L.R.C.S.I. is submitted are efficient tests both of prolonged study and of actual competency, not only in surgery, anatomy, and physiology (which might be considered the specialities of the College), but also in medicine, theoretical and clinical pathology, therapeutics, and midwifery. We insist, therefore, that the L.R.C.S.I. holds proof that he possesses a good working knowledge of every branch of his profession, and if he went no further for his diplomas than the College of Surgeons it would be unjust to stigmatise him as "half educated." But as a fact nineteen-twentieths of the Licentiates of the College do go further, and do take a medical diploma (the majority of them the L.K.Q.C.P.I.), because the rules of the public service compel them to do so, and thus their capacity as physicians is additionally guaranteed.

If these be the facts, we ask *cui bono* would it be to drive all licentiates through the one gate, whether they liked to go that road or not? Would it not rather aggravate the "half qualification" abuse in Ireland by forcing students to go to the Apothecaries' Hall, where the restriction of the examination to medicine, pharmacy, and botany is in full swing?

If Dr. Kidd feels as strongly as he writes respecting the existence of these half-education licences throughout the Kingdom, we would ask his reasons for opposing, as he has always done, the Medical Reform Bill, which would wipe out these abuses, not only in Ireland, but in other places where they exist to much greater extent?

It seems to us strange that any one who feels thus can content himself with the remedy of an abuse (assuming such to exist) in one corner of the Kingdom while he regards with complacency its continuance in a much more aggravated form elsewhere.]

THE MEDICAL ACT AMENDMENT BILL

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—We cannot be too thankful that the Parliamentary Session ended before the Medical Act Amendment Bill became law, and that we now have breathing time to consider the policy of that Bill.

There has been more than enough of hasty legislation

affecting other classes in this country, and it behoves us to understand what was the drift of the lapsed Act of last session, so that it may not come on us by surprise if legislation on the same lines should be attempted (as it probably will) in the next session of Parliament.

In few words it may be described as disestablishment of all the medical and surgical corporations as licensing bodies. Phrases go for a good deal, and the "one portal system" are words to conjure with.

There seems to be a vague notion in the minds of many that if the Government stamp were impressed on the final qualification for medical and surgical practice, it would tend to raise the standard of education, and also the social status of the general body of men practising in the United Kingdom. Well, I doubt it. Will any one really say that the fact of the final examination being in the hands of a Government board would send back any man who has gone so far as the "final" to another walk in life? or check the influx of large numbers into the ranks of the profession? or tend to raise the profession socially or educationally? The effect on some of the Colleges would be simply ruinous. They would practically cease to be licensing bodies in the true acceptance of the term, and would sink into the useful, but not very dignified, position of mere teaching schools.

Let us consider what would be the probable effect on one institution to which many of us are attached—our Irish College of Surgeons. There are proud memories connected with that College during the hundred years of its existence, and no one can say that it has failed in its trust. Yet, if a Bill similar to that of last Session becomes law, the diploma of the College will no longer be a legal qualification, unless it is supplemented by the *imprimatur* of an examining board of the future.

I think, therefore, we have a right to ask the men who are responsible for the present policy of the College of Surgeons not to leave a diminished inheritance to their successors, but to oppose legislation which is not demanded by any section of the public, so far as I can see, and which will lead at no very distant day to the extinction of that College practically. For if it is not to give a full and final qualification in surgery, for what will it exist?

Public opinion within the ranks of the profession has never been turned to this subject. Perhaps it may have been discussed at Council meetings, where the most fluent talker or the most pertinacious arguer usually gets his way; but I say advisedly that the policy of the Medical Act Amendment Bill of last Session is very imperfectly understood by the profession generally. The brief outline of the Bill given in the last *Medical Press* comes very opportunely, and, in my opinion, it plainly shows that that Bill was not calculated to benefit either the profession or the Colleges. I beg leave, therefore, to suggest that, as the question is one of vital importance, a meeting of the Royal College of Surgeons should be convened, without loss of time, to consider the matter. I am sure the Fellows from all parts of Ireland would attend such meeting, and the subject would be fully and adequately discussed.

I am, Sir, yours, &c.,

F.R.C.S., an ex-President of the
10th Dec., 1883. Irish Medical Association.

Literature.

RINGER'S HANDBOOK OF THERAPEUTICS. (a)

A TEXT-BOOK which has reached its tenth edition scarcely needs an introduction to the profession. The book retains most of its former characteristics; indeed, the bulk of it remains in the same words. New paragraphs are, however, interspersed, chiefly on so-called new drugs, or on such as the author has experimented with. Thus we find the substance of his article on permanganates reproduced, and his other communications to the journals are similarly honoured. In some instances the observations of others are noticed. Fraser's results with ethyl-atropium are epitomised, so are Murrell's with nitro-glycerine, and some others. It may be questioned if these are of much service to students. In fact, the book, as a whole, is more fit for

practitioners, as it abounds with hints from various sources as to empirical remedies in various states. For study, therefore, it is far inferior to scientific works and more methodised treatises. Here and there, however, there are articles in which an effort has been made to rise to a scientific treatment of the action of a drug. In other cases the feebleness is extreme. For example, *Grindelia Robusta* gets a short article telling us that it has a reputation for asthma in America, and although the author's experience with it is slight he has not realised the expectations he formed, which is a considerable admission from Dr. Ringer, who seems very ready to find the virtues he hears of in any drug. To this he adds "it is also used in chronic pyelitis and chronic cystitis." Really such a weak account might as well have been omitted. The preceding article is on Gelsemium. Here, of course, we get a summary of Ringer and Murrell's former journal communication and little else. But the article closes in a characteristic way. The author says, "I have found tincture of gelsemium in ten minim doses, thrice daily useful in some cases of Menière's disease. In five-drop doses, repeated every quarter of an hour, the tincture is said to be useful in gall-stones." The two points here brought together seem only connected by their weakness and want of any scientific basis. Surely, students want to know something different from this, and the empiricism indicated is more worthy of the dark ages than the nineteenth century. Dr. Ringer then mentions a case which gets relief in five minutes after the first dose, adding "the relief is quicker if she walks about." (!) No more gall-stones, eh? Perhaps what is equally remarkable is, that the author here breaks off to insert as a separate paragraph in a different type these words:—"A tumbler or two of hot water with a teaspoonful of carbonate of soda is said to relieve the pain of gall-stones." This would be very well if therapeutics were to consist of a series of hints on diseases and drugs, but in a professedly systematic treatise looks out of place amidst the maladies for which gelsemium has been tried; for the author at once returns to enumerate under these latter, tetanus, mania, sleeplessness, and dysmenorrhœa. We do not give these instances to find fault but to illustrate Dr. Ringer's method. His book is, however, popular notwithstanding, and perhaps even because of its defects. Still we should have preferred to see an attempt to present the scientific aspect of therapeutics to practitioners. We are not surprised that pure empiricists and homeopaths claim the author as one of themselves, and that the latter accuse him of stealing their special remedies. Absurd as such claims may be, some countenance is undoubtedly given them. The author will, no doubt, understand that a few criticisms on a book in its tenth edition will not be out of place, and the success of the work leads us to offer them. We should add that the book now opens with a brief account of the symptoms of disease. This is somewhat of the same nature as the rest of the book, and if its place may be questioned, will no doubt be useful to many students, since diagnosis is too often studied by exclusive methods, the old symptoms receiving scant attention from teachers. This part may, therefore, be read with advantage by students, though old practitioners will feel inclined to dispute the correctness of much that is here laid down as fact. The notice of new fads, leaves too little room for many old drugs. So squills, jalap, scammony, senna, &c., are put off with a few lines each in the end of the book, and this must give students a very incorrect idea of the relative importance of remedies, but as we have said, this is scarcely a students' book so much as a practitioner's, and should not be relied on for examinational purposes. Mr. Lewis has brought out this edition in a form equal to its predecessors.

Royal Institution of Great Britain.—The ordinary lecture season will begin next week. Mr. R. Stuart Poole is to give the first of two lectures on "The Interest and Usefulness of the Study of Coins and Medals," on Tuesday, January 15. Professor Ernst Pauer will, on Thursday, Jan. 17, give the first of a course of six lectures on "The History and Development of the Music for the Pianoforte and its Predecessors." And on Saturday, Jan. 19, Professor Henry Morley will give the first of a course of six lectures on "Life and Literature under Charles I." The Friday evening meetings begin on the 18th inst., when Professor Tyndall will give a discourse on Rainbows.

Notices to Correspondents.

THE ROGERS TESTIMONIAL FUND. (NINTH LIST.)

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The following additional subscriptions have been received since the announcement in last week's number of the *Medical Press*.

Yours, &c.,

J. WICKHAM BARNES, Hon. Sec.

Poor-law Medical Officers' Association,
8 Bolt Court, Fleet Street, London, January 7, 1884.

An Admirer of disinter- ested work ..	£5 0 0	Dr. A. Robertson ..	£0 10 0

GUARDIANS AND GUARDIANS.—That justice and consideration may occasionally be expected by medical officers of boards of guardians was shown in a striking manner last week, when the Whitechapel Board (East London) carried unanimously a superannuation allowance of £325 to Dr. Liddle on his resignation of the post of medical officer of health for that district, coupling therewith a vote of thanks and appreciation of Dr. Liddle's past services. This is as it should be, not as it usually is.

AN UNAPPRECIATED RISK.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR DR.,—In view of the fact that the matter discharged from mucous patches in syphilitic cases is inoculable, is it not, in your opinion, possible for such contagion to be conveyed through contact with the cup used in Holy Communion?

Have you observed any case in which this accident has occurred?

If more than one case observed, please state how many.

Is it customary for the clergy, in your experience, to use a napkin to wipe the cup before passing to the next communicant?

How many do you know of who take this precaution?

Is such protection, in your opinion, necessary or advisable, and is the napkin sufficient?

The cup is passed so rapidly from mouth to mouth, is not the danger great enough for the medical profession to caution the clergy on this subject?

Any further information or suggestions which you may feel inclined to offer will be gladly received, and the early return of this paper with your answers respectfully solicited.

Yours, &c.,

W. THORNTON PARKER, M.D.

Morristown, N. J., December 17, 1883.

[If syphilis were as readily communicated as our correspondent apprehends, no human being would lack a sore throat or papular eruption. For his behoof we beg to say that we never observed such a case, never heard of one, or heard of anyone who heard of one; never knew a clergyman to use a napkin for such a purpose, and would think him a fool if he did; and have no information or suggestions to offer. We do not suppose that our readers run much risk of acquiring disease that way.—ED.]

MR. AMERY.—Do not give up the attempt. The design is one most likely to succeed, although, perhaps, not quite immediately. It is also likely to be attended with desirable consequences, and should be persevered in.

DR. ROBERTS.—The announcement is premature.

MR. GRAHAM.—Sulphuretted hydrogen is a plentiful product of decomposition in such situations, and the effect that it would exert on metal articles would be to blacken those of which the sulphides are black in colour, such as silver and lead. Chemical analysis cannot be studied with any degree of success in the absence of practical laboratory work.

MEETINGS OF THE SOCIETIES.

WEDNESDAY, JANUARY 9TH.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown.—Dr. E. S. Tait, On Observations of Puerperal Temperature.—Dr. J. Williams, On the Corroding Ulcer of the Os Uteri.

EDINBURGH OBSTETRICAL SOCIETY.—At 8 p.m., Exhibition of Specimens.—Dr. Halliday Croom, Microscopic Preparations of the Membrane in Membranous Dysmenorrhoea.—Dr. A. H. F. Barbour, Preparations of Kyphotic and Kyphoscoliotic Pelvises.—Dr. Milne Murray, Heart of a Child with Perforate Septum Ventriculorum. Sent by Dr. Haig Brodie, Farnham.—Robert W. Felkin, Notes on Parturition in Central Africa. Communicated by Dr. Halliday Croom.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 7.30 p.m., Council Meeting.—At 8 p.m., Surgeon-General Hunter, On the Origin of the Cholera Epidemic of 1838 in Egypt.

HUNTERIAN SOCIETY.—At 7 p.m., Council.—At 8 p.m., Mr. Reeves, On the Treatment of Rectal Stricture, with special reference to Inguinal Colotomy.—Mr. Charters J. Symonds, On the Reliable Signs of Fracture of the Neck of the Femur.

ROYAL MICROSCOPICAL SOCIETY.—At 8 p.m., Ordinary Meeting.

THURSDAY, JANUARY 10TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At 8 p.m., Living Specimens.—At 8.30 p.m., Discussion On Sympathetic Ophthal-

mitis (adjourned from last meeting).—Mr. Simeon Snell, On Two Cases of Retinal Glioma, in one of which Shrinking of the Eyeball occurred without Perforation.—Dr. G. A. Brown, On a Case of severe Conjunctivitis, with Formation of Membrane on the Cornea, caused by Whisky thrown in the Eyes.—Mr. Henry Eales, On complete Paralysis of Convergence and Accommodation in a Girl aged thirteen.—Mr. J. B. Story, On the Treatment of Cystoid Cataract.—Mr. A. Stanford Morton, On Congenital Absence of Lacrymation in a Boy.—Mr. M. Hardy, On some Clinical Observations which appear to indicate a means of reducing the Danger from Malignant Glaucoma while increasing the efficacy of Iridectomy in the Treatment of Chronic Glaucoma.

FRIDAY, JANUARY 11TH.

ACADEMY OF MEDICINE IN IRELAND (Surgical Section).—At 8 p.m., Living Specimens.—The President: (1) A young girl, set 18, after Removal of enormously hypertrophied Breasts, largest weighed 20 lbs.; (2) Excision of Knee in a boy set 11 for Caries; (3) Child a year after Hare-lip Operation (by Exhibitor's method).—Mr. Stokes, Case showing result of Excision of the Upper Jaw for Fibro-Sarcomatous Tumour, probably originating in the Antrum. Specimens exhibited by card.—The President, Vesical Calculi removed by Lateral Lithotomy.—Mr. Stokes: (1) Amputation at the Hip-joint, parts removed in, on account of a rapidly growing Sarcomatous Tumour on inside of Thigh; (2) Cast of the Thigh, showing Size and Position of the Tumour; (3) Multilocular Ovarian Cyst recently removed from a patient set 47. Papers:—Mr. Stokes, The Radical Cure of Hernia by Peritoneal and Intercolumbar Suture.—Mr. Barton, On the Radical Cure of Strangulated Hernia.—Mr. Kendall Franks, The Radical Cure of Hernia by the Method of Dissection.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Annual General Meeting for Election of Officers and Council.—Dr. J. K. Fowler, On a Case of Subcutaneous Nodules.—Dr. Cockswell, On a Case of Cortical Tumour, with Unusual Frequency of Epileptiform Attacks.—Dr. R. J. Lee, On a Second Case of Creeping Eruption.

MONDAY, JANUARY 14TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At 8 p.m., Annual General Meeting for the Election of Officers for the ensuing Session.—Casual Communications by Mr. Morton Smaile and Mr. Storer Bennett.—Paper by Mr. Bland Sutton, On Comparative Dental Pathology.—Valedictory address by the President.

Vacancies.

Birmingham General Dispensary.—A Resident Surgeon. Salary, £150, with £30 for extras, no board. Applications to the Secretary before January 15.

St. Pancras, Middlesex.—Dispenser. Salary, £100, with dinner daily. Applications to the Clerk to the Guardians by January 14.

Sussex County Hospital. Physician and Assistant Physician (Honorary). Applications to the Secretary by February 6.

West Herts Infirmary, Hemel Hempstead.—House Surgeon and Dispenser. Salary, £100, with board, &c. Applications to the Secretary by February 6.

Appointments.

ELGOOD, C. R., M.B. Lond., House Surgeon to the North-Eastern Hospital for Children, Hackney Road, E.

HOLYOAKE, E., M.B.C.S., House Surgeon to the London Hospital.

HUDSON, E., M.B.C.S., Junior House Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

JOHNSTON, R. H., B.A., M.B., B.Ch., Medical Officer to the Bungay District of the Wandford Union.

MADDEVER, J. C., M.D. Glas., Medical Officer of Health for the Brownhills Urban Sanitary District.

MILLS, W., L.R.C.P., L.R.C.S., Resident Medical Officer to the Chorlton-on-Medlock Dispensary.

MONEY, A. M.D., M.R.C.P., Physician to the Victoria Park Hospital for Diseases of the Chest.

NANON, H. C., M.R.C.S., L.R.C.P. Lond., Junior Resident Medical Officer to the Hospital for Children, Pendlebury.

SHEILD, A. M., M.B., F.R.C.S., Resident Obstetric Assistant to St. George's Hospital.

THOMAS, A., L.R.C.P. Ed., L.R.C.S. Ed., Assistant Medical Officer to the Walton Workhouse, Liverpool.

WILLIAMS, M., L.R.C.P. Lond., M.R.C.S., Registrar and Pathologist to the North-Eastern Hospital for Children.

Births.

HALEGOOD.—January 2, at Upperton, Eastbourne, the wife of Hy. Halegood, M.D., of a daughter.

Marriages.

HOWLETT—HUTCHINS.—January 3, at the parish church, Gosall, Staffordshire, Edmund Henry Howlett, F.R.C.S., of Hull, to Amy Lavina, only daughter of Rev. Richard Masters Hutchins, of Stocklynch, Llanilthorpe.

Deaths.

GAYLEARD.—December 22, at his residence, Holloway, London, N., John Gayleard, M.B.C.S., aged 74.

KEELAN.—At his residence, Dunlee, P. Keelan, M.D.

LEES.—December 27, at Ashton-under-Lyne, Samuel Duncroft Lees, M.D., and J.P. of the County of Lancaster, aged 70.

RECENT METHODS OF TREATING COLD ABSCESSSES. (a)

By THEODOR BILLROTH,

Professor of Surgery in the University of Vienna.

WHEN we turn our thoughts to a cold abscess we must first of all place before ourselves the questions, Why is not the contained fluid absorbed? and why are we compelled either to await its opening or open it ourselves?

Exudations that arise in the course of acute inflammations, or transitory disturbances of circulation, are indeed usually absorbed; if the general condition of the body is in other ways normal, the absorption of the fluid is the ordinary process. If you have a clear conception of the arrangement of the lymphatic vascular system, you will comprehend this, for the lymphatic vascular system sucks up all these exudation products like a sponge, and carries them all back into the blood channels. Under what conditions, then, does this resorption fail to take place? 1. You may say first that absence of open lymph vessels is a very important cause, and that is just the case with the capsule that in the course of time forms around these abscesses. The walls of the veins can, it is true, take up some of the fluid, but it is the open lymph vessels that are most concerned in such absorption. But even when such open lymph courses are present, they may become closed under certain circumstances, as by an exudation that becomes clotted, in which fibrine forms quickly, and in which the clotting may be continued into the lymph vessels, or into the interstitial structural interspaces. This is the case to a great extent in croupous and diphtheritic exudations. 2. The resorption is dependent on the degree of concentration of the fluid. If the fluid is to be resorbed, its concentration must be less than that of the blood. That is not the case in cold abscesses. Moreover, the various regions of the body show great differences in

their power of resorption: the pelvis is the most favourable for resorption; the most unfavourable is the pleural cavity. How can we overcome these difficulties therapeutically? 1. The first method would be the removal of the fluid; but experience teaches that the fluid may be removed for the moment, but that the exsudative property of the structure does not cease; on the contrary, the cavity refills with uncommon rapidity with pus, this refilling being principally caused by the fact that by removal of the fluid the vessels in the abscess walls are subjected to a greatly reduced pressure. 2. Is it possible by certain irritating agents to excite a greater vascularity in the walls of the abscess? With this object in view tincture of iodine has been injected, for the purpose of exciting an inflammation, whereby an exsudation is certainly set up, but which, in consequence of the higher vascularity thus induced, is readily absorbed, with the result that the cavity shrinks up. 3. This method was necessitated by the opening of the abscess under strict antiseptic precautions. Not only is the pus evacuated, but the abscess cavity is carefully scraped with the sharp spoon, after which an antiseptic dressing is applied. In this way the walls of the abscess, which consist of a mass of soft granulations, are removed as far as the healthy tissues, whereby, by means of a light compress, healing by first intention has been achieved. Indeed, by this method good results have been obtained in many cases, but it is one that requires to be carried out with great accuracy. Since the introduction of iodoform we have strewn the scraped-out cavity with iodoform in powder, and brought the edges together with the exception of the openings left for drainage. By means of iodoform sepsis is to a great extent avoided, and under certain circumstances granulations may spring up under which healing rapidly takes place. 4. Quite recently we have attempted another method—viz., puncture of the abscess, and subsequent injection of an emulsion of iodoform consisting of 10 parts of iodoform to 100 parts of glycerine. The emulsion must be well shaken up before using, and then, according to the size of the abscess, 20 to 30 grms. are

(a) Translated from the *Allgem. Wien. Med. Zeitung*.

to be injected. In most of the cases in which this method has been attempted the course has been free from reaction, only moderate swelling has taken place, and but little pain has been present. This, however, would only indicate that the treatment has done no harm; it is also desirable that it should bring about the shrinking of the abscess, and that the fluid remaining in the cavity should be absorbed. As a matter of fact, the results in some cases were exceedingly favourable, but further experience is necessary to show whether the iodoform emulsion is still to be continued. Generally speaking, I should advise you, unless there should be some reason for it, not to open the cold abscess, but to allow it to open spontaneously, especially if you cannot watch over your patients closely. You can then calculate with certainty that the pus will escape without fever and without further reaction, whilst at the same time the entrance of air is completely avoided. In such cases the mechanical relations are extremely favourable, even wonderfully so, without our being able to give an explanation of them, for it happens, for example, that an abscess bursts into the bladder or rectum, and in such cases I have never seen urine or intestinal gases enter the abscess cavity. Under strict antiseptic precautions, and under your constant supervision, you may open the abscess, especially if you suspect with some certainty that you can easily reach the bone from which the abscess springs, or if it causes by its great expansion compression of the neighbouring structures, and in consequence of this gives rise to various difficulties.

A Course of Lectures

ON

THE EYE: ITS DISEASES, AND THEIR REMEDIES.

Being an Abstract of a Course of Lectures delivered in the Royal College of Surgeons in Ireland

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
Professor of Ophthalmic and Aural Surgery in the College;
Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 3.)

Sequels of Conjunctivitis **THREE** well-defined pathological conditions which demand the attention of the surgeon may be classed as the sequels of conjunctivitis:—

- a. Granular hypertrophy of the conjunctiva.
- b. Pannus, or vascular engorgement of the cornea.
- c. Xerosis, or degeneration of the conjunctival mucous membrane.

One of these (pannus), while it is constantly associated with chronic conjunctivitis, is a corneal disease, and will be referred to, in due course, as such.

The first effect of a conjunctivitis is engorgement of the palpebral conjunctiva, which—as I have said—is much more vascular than the ocular portion, the result of this engorgement, if prolonged, being the enlargement of the papillæ and sub-mucous tissue, and eventually the production of an excessive hypertrophy of these structures, a condition known as granular conjunctiva, which is very prevalent amongst the lower classes.

Many authors regard this condition not as a sequela of conjunctivitis, but as a specially contagious form of ophthalmia, and they describe the catarrhal ophthalmia which precedes granular hypertrophy, under the name of granular conjunctivitis. I do not, however, agree in this view, having seen granulations developed as a sequela of all forms of conjunctivitis from the simple hyperæmia conjunctivæ up to the most violent blennorrhœa. Nor do I believe in the essentially contagious character of the disease, because I have experience that it commonly develops without contagion where over-

crowding and vitiated atmosphere exist, and that—although it may be imported where numbers of people are congregated—it does not spread unless these prejudicial conditions are present.

I have seen many cases of granular hypertrophy following upon the conjunctivitis of measles and of gonorrhœa without any of the causes which ordinarily produce granular ophthalmia.

No matter what the exciting cause of granular hypertrophy may be, it never develops to any serious extent without the contributory causes of bad air and dirty habits. Hence it is seen amongst the better classes only in cases in which attacks of ophthalmia have been mismanaged by keeping the patients shut up in close rooms, but amongst the lower orders in Ireland it is fearfully prevalent, so much so that in the squalid districts in Dublin and other crowded cities a majority of the population has had experience of the disease at some time of their lives.

Granular conjunctiva may, in fact, begin from any ophthalmia, and even, as I have already shown you, in a mild degree from the chronic congestion of the membrane (hyperæmia) which arises from local irritation or strain of the accommodative apparatus. It is, however, most frequently the result of bad hygienic conditions, and is excessively frequent amongst the Irish peasantry and the Eastern races. The ophthalmia which precedes it is very common, especially amongst children in workhouses and other public institutions where large numbers are congregated, and where the dietary and the air space is low. But any low condition of health, if accompanied by impure air and dirty habits, is very favourable to its production. In Ireland it is said that the pyroligneous acid exhaled from turf fires in cabins where there is no efficient ventilation is a contributing cause, but the disease is even more frequent in the squalid tenements of the city than in country cabins.

Granular Conjunctiva.—Strictly speaking, the affection should be divided by its pathological character into three different—

- a. Trachoma, or “sago-grain” granulation.
- b. Granular hypertrophy of the papillæ.
- c. True neoplastic granulation.

But in practice these three diseases resolve themselves into three stages of the same disease, and always exist together in chronic granular conjunctiva. In the advanced stages the deep structures of the conjunctiva become infiltrated, thickened, and hardened, and a condition is produced which is incurable, and which frequently gives rise to ectropion, or inversion of the lid, and to other serious troubles.

The earliest condition of granulation (trachoma or “sago-grain” granulation) is usually to be seen in “vesicular” eminences within the lower lid, but these are of frequent occurrence after slight attacks of conjunctivitis without the development of true granular conjunctiva of the upper lid. They are formed by the swelling and hypertrophy of Krause’s lymphatic follicles, which lie beneath the conjunctival epithelium, but are not visible in the healthy eye, and they are soft and pulpy, and mostly to be found within the lower lid, giving little trouble to the patient, even when fully developed. They are premonitory of the hypertrophy of the papillæ which constitutes the second stage of granulation, and are hidden from view when that hypertrophy commences, and they are supposed to form the groundwork of the third, or chronic form of granulation, in which new warty growths are formed.

The second form of granular conjunctivitis is the hypertrophy of the papillæ of the lid which becomes visible on eversion of the upper lids in a roughened condition varying in degree from minute sandy-looking granulations to large vascular wart-like growths, by which the smooth delicate lid surface is converted to a coarse, furrowed, rough condition. The character of the granulations also varies; in the most recent cases it is

highly vascular and pulpy, in the more chronic states it is paler and much harder, and more warty, this being the most intractable form of the disease. Accompanying this

Fig. 7.

condition there is always a more or less inflamed state of the ocular conjunctiva, and in all chronic cases more or less of the thickened and vascular condition of cornea known as *pannus*.

In the third stage the papillary hypertrophy has nearly disappeared, but it is replaced by the enlarged, hardened, and warty granulations which are a neoplastic growth from the conjunctiva. They present much less vascularity and less disposition to enlarge than the hypertrophied papillae, but they cause much greater discomfort and injury to the eye, and they never entirely disappear without treatment. If they have existed for any considerable time the cornea becomes quite opaque from vascular infiltration, and we have the condition above described as *Pannus*. After a very long period, extending, perhaps, over years, the induration gradually increases, and the granulations shrink away, leaving the lid conjunctiva atrophied and shrunken.

Eventually the conjunctiva becomes flaccid and vascular, the edges of the lids bleary and inflamed, the cornea more or less vascular and hazy, and sight is seriously impaired.

(To be continued.)

SOME DIFFICULTIES MET WITH IN THE EMPLOYMENT OF REST AS A THERAPEUTIC AGENT IN MEDICAL CASES. (a)

By WILLIAM DYSON, M.D.,

Physician to the Sheffield Public Hospital and Dispensary.

IN this short communication it is proposed to deal with that variety of general rest to the whole organism which is obtained by keeping a patient in bed in the horizontal position. No apology or excuse need be asked for the introduction of a subject which rather concerns management than medicine; and at these times, too, when "therapeutic tips" are so fashionable, and "tip-and-go" practice not difficult to demonstrate; in these days, too, when massage and kinesitherapy threaten to run Rest off the platform of therapeutics, and when it is proposed to treat restlessness and insomnia by vibratile percussions, with a special instrument for the purpose.

It is not proposed to deal with the subject under six or seven heads, after the manner of some writers, nor to prove or insist on the common platitudes concerning rest as a valuable therapeutic agent. With these latter we are all fully conversant; but it is not so certain that in the treatment of medical cases, and especially of acute febrile diseases, we always practice according to the light we possess, or fully appreciate the value of this remedy.

Personally, the chief difficulty experienced by the writer, has been the application of these principles, even when fully recognised. At some time or other in the treatment of an acute case the practitioner is sure to be asked the question, "Please, doctor, may I get up?" It may be shouted after him when, hat in hand, he is racing downstairs; or, what is more fre-

quent in its occurrence, the doctor delays his visit till afternoon and finds that his patient has already decided the question for him, and is sitting up by the fire, "just for a little change, you know, as bed is so weakening." The next day the patient may or may not be suffering from a serious relapse of his malady. If the relapse occur, the sufferer is severely blamed; if not, he will be told that he is more fortunate than wise. But what shall we say about those cases in which the question has not been too well considered by the doctor in which sitting up brings a relapse? Or what can we say of those when all things progressing favourably, a well-considered permit to get up is given, and yet a relapse occurs?

This point is more easy to describe than to define, and the brief recital of a few clinical illustrations will assist us materially to appreciate this difficulty.

CASE I.—J. F., *æt.* 14, was admitted, under the writer's care, to the Sheffield Public Hospital, on July 14th, 1883. He had suffered six days previous to his admission, and presented the classical symptoms of a moderately severe attack of rheumatic fever. He was put to bed, on milk diet, and ordered to take salicylate of soda in mixture, *gr.* xv. every four hours. In twenty-four hours his temperature was subnormal; pulse, which was slow on admission, became 40 per minute and very intermittent. Salicylates were then stopped; perchloride of iron mixture ordered. After he had been in bed a week, his temperature being normal, free from joint pain, secretions normal, he was allowed to get up on the thirteenth day of his illness. He dressed, walked across the room, and sat by the fire. That same night his temperature rose to 102.6 deg. Fahr.; he passed a restless night, had slight return of the pain, and seemed as if he would have a bad relapse. Next day he was kept in bed; iron mixture continued. After three days his temperature was normal; he appeared well again. On July 27th, nineteenth day of illness, he was allowed to get up again. This time no evil effects ensued, and his recovery was shortly complete.

Now, we ask, how could one know that he would go wrong on getting up on the thirteenth day? Why did a relapse not occur on the nineteenth day? His temperature was normal for a week; he was free from joint-pain for a like time; pulse much improved; no endocarditis; urine normal; no perspirations; was cheerful; eating well. Why should he not get up when he asked? and yet the relapse was threatening.

CASE II.—A. W., a young grinder, *æt.* 18, admitted to hospital on July 14th, 1883; suffered fourteen days before admission. On admission his left pleura was full of fluid, left lung hepatized, pericarditis; temperature 103 deg. Fahr.; pulse 120. Pericardium subsequently became full of fluid. In four days under rest in bed and treatment his temperature became normal. The absorption of the fluid was initiated, and probably enhanced, by the administration of Pot. iodid. internally, and blister externally. His temperature remained normal; his condition, both local and general, gradually improved. On August 3rd, without leave, he got up, went across the ward, and sat by the fire. That same evening his temperature rose to 102 deg. Fahr.; his symptoms, both general and local, became worse. Subsequently he was kept in bed under strict supervision, and he gradually improved. On August 15th he was told to get up. From this date he got up daily, and his convalescence proceeded satisfactorily.

Again we ask, why did the case go wrong on August 3rd, and go right on August 15th.

CASE III.—J. D., male, *æt.* 48, admitted to hospital on July 12th, 1883. This was one of those very obstinate case of relapsing acute rheumatism. He was in hospital for three months; he never had any cardiac complication. Drug after drug was tried with only temporary benefit; relapse after relapse occurred. The

(a) Read before the Sheffield Medico-Chirurgical Society at the meeting on Dec. 20th, 1883.

last four relapses were distinctly caused by getting the patient up, and subsided on keeping him in bed.

Why should not one get him up? His appetite good; his secretions normal, according to ordinary tests; his rheumatism apparently gone. Why should we restrain him? If so, what are the principles of our restraint?

Experiences of this kind might be multiplied indefinitely from one's observations on cases of rheumatic fever and chest diseases.

CASE IV.—J. McN., æt. 60, a case of a different kind and with a different issue. Admitted Oct. 12th, 1882, suffering from Bright's disease. General anasarca; bronchial and lung congestion. Urine—6 oz. per diem, loaded with albumen. He was kept in bed on milk diet; ordered to take hot bath occasionally, and powder of pulv. jalap co. and ppt. tartarat. every other morning. Under this regimen anasarca disappeared, quantity of urine increased to 1½ pints daily, and relative amount of albumen greatly diminished. In three weeks he was allowed to get up, but still kept on milk diet. The albumen increased and urine diminished in quantity. The dropsy did not re-appear. He was put to bed again for a week; again the urine improved. In sixth week he got up, and in a few days left the hospital. Now, with a moderately strict diet and rest in bed, this man might prolong his life indefinitely. If a man be poor, he cannot afford to do it. If the case be rich, an equally insurmountable difficulty is presented to the practitioner by the patient who frequently positively declines both the galling rest and the restricting diet.

We cannot discuss here what should be the principles of our choice of this remedy, Rest. It is too wide a subject. But given the fact that we have wisely or necessarily chosen the remedy, when may we leave it off? It is prominently taught in some schools that temperature is the most valuable guide in helping us to decide when a patient may get up after an acute febrile disease. The above cases show how utterly this can fail. The feelings of the patient are proverbially unreliable. We seem to have no guides to help us. Improving local conditions, freedom from pain, quiet, steady pulse, normal temperature, good appetite, normal secretions look well; but again and again one has to proceed in a tentative, empirical kind of way; to let the patient try—if he succeed, well and good; if not, send him back to bed a bit longer, and then try again.

In the next place, one may revert briefly to the difficulty, anxiety, and trouble which children give us in the application of this principle of Rest. In the many acute febrile complaints, frequent in their occurrence, endless in variety, and diabolically insidious in their deeper significance, to which children are liable, we admit the immense importance of rest and warmth in bed. We have, however, three gauntlets to run to get it—firstly, want of decision on our part; secondly, obstinate prejudice of the parents; and lastly, the whim of the little patient himself. He will be up and running about, if he can raise his head at all. The difficulty is prominently manifest in acute rheumatism in children. The immense experiences in this matter recently given to the profession by Dr. Thos. Barlow and others teaches us and proves to us what had long been surmised—viz., that children have febrile attacks in which the fever is small in amount and short in duration, in which rheumatic perspirations may be entirely absent, and, if present, are but little acrid, the joint mischief slight and ill-defined, and yet under this mask is the foul face of endocarditis and pericarditis. The conclusion comes to we must now universally agree with, that keeping a child in bed a day or two for slight rheumatic pains often has a tremendous influence on its future life. But then comes the question of the difficulty of obtaining this rest in bed, and this obstacle will be testified by the majority of practitioners.

Old people present a difficulty in management by rest in bed. It has been lately the luck (good or bad) of the writer to see a goodly number of patients over 80 years

of age, suffering from various sub-acute febrile ailments. It is his general practice to get them up out of bed as speedily as possible. If left in bed too long, everyone knows how liable they are to get congestion at the bases of the lung, staggering pulse, dry, brown tongue, liver inaction, lethargy, and slight wandering, all of which are unpleasant symptoms. On the other hand, if got up too soon, it is proverbial how susceptible to cold and changes they are. A few weeks ago an old man, æt. 87, was very successfully operated on by Mr. S. Snell for cataract. On the third day he was got up; the next day he had some slight bronchial catarrh, and he stayed in bed for several days. At this time the writer saw him in consultation; he had slight bronchitis, very little congestion of lung, dry tongue, confined bowels, great lethargy, and slight wandering at night. By free stimulation, a mild aperient, and getting the patient to sit up in bed as soon as possible, the symptoms passed off, and he made a good recovery.

Such are a few of the difficulties experienced in this subject during the past few months; and, while acknowledging the great value of rest as a remedial agent, we must admit the practical application of it is just as difficult to administer as diet and physic to which it is such an important auxiliary.

Clinical Records.

CASES IN PRIVATE PRACTICE.

Modified Glanders in Man.

Under the care of Mr. ARTHUR MARSACK,
L.R.C.P., L.R.C.S. Ed.,

One of the Medical Officers to the Tunbridge Wells Provident Dispensary.

A HOUSEHOLD of nine people, three of whom are adults, and the rest children, ranging in age from three months to twelve years, were attacked by the following symptoms:—All of them had felt unwell for a few days, and had had diarrhoea in a more or less severe form, the adults being more affected than the children. Without any rigors or marked change in the temperature, this attack of diarrhoea was followed by swelling of the sublingual and sub-maxillary glands; a thin, and afterwards thick, discharge from the nostrils which stained the handkerchief yellow, and simple ophthalmia (conjunctivitis) of one or both eyes—in seven of the cases of one eye first and then the other—and a pustular eruption on the face, especially below the eye and nose, the surrounding skin being of a bright red colour. Only one of the adults had this eruption, but all of the children were affected with it; the youngest of all, a baby of three months, had it below the chin in the fold of the neck where it discharged profusely.

In the children all the symptoms, except the diarrhoea, were more marked than in the adults, and their effects more lasting. The swelling of the glands was in every case of a sub-acute type, and suppuration did not take place in any one case. There were no rigors, and there was no rise in temperature to usher in any of these symptoms, and in most cases the conjunctivitis co-existed with the eruption and the swelling of the glands. The conjunctivitis lasted from five to seven days in the adults, and from nine to twenty-one days in the children; the discharge from the nose about ten days; the glandular enlargement nearly a month; and the eruption, which, although it co-existed with the other symptoms, has not in all cases disappeared, some traces of it still remaining in the younger children (six weeks from its commencement). The local treatment was a lotion of zinc sulphate (gr. ij. ad oz. j.) for the eyes, bread poultices to soften and clean up the discharges from the eruption, which latter was afterwards treated with unguentum zinci. Internally, the syrup of the iodide of iron was given in varying doses, proportionate to the age of the patient, and change of air was prescribed, with most beneficial results.

Remarks.—My reasons for thinking the above to be cases of modified glanders are the following:—The house, the inmates of

hich were affected, lies in a valley, and on the hill facing it there is a slaughter-house where horses are killed for dogs' meat. The entrails, &c., of these horses are buried in a loose soil composed of decayed leaves, and the rain we had in the summer and autumn would be sufficient to wash the decomposing remains into the valley, which is so well protected by trees that the sun has little opportunity of striking into the ground until the leaves have fallen. Unfortunately, in the interest of science, there are no other animals, except human beings, in this small valley which would be affected by glanders, and as the men in charge of the slaughter-house deny that any but healthy horses were killed there, I have no conclusive proof that this disease, which I have endeavoured to describe, is modified or attenuated glanders but the experiments of Pasteur and others have shown that the bodies of diseased animals propagate through the soil the diseases from which they suffered, in an attenuated form.

CASES IN HOSPITAL.

ROTHERHAM GENERAL HOSPITAL.

Abscess of Anterior Mediastinum following Injury—Pleurisy with Effusion—Recovery. (a)

Under the care of Mr. BERNARD WALKER, M.R.C.S.

R. W., *æt* 17, was received into the Rotherham Hospital on the 9th October, 1882. Whilst at work, he was struck on the chest by a red-hot bar of metal coming from the rolls. He complained of severe pain in the back and chest, breathing was quick and shallow (restricted probably by the pain). Auscultation sounds normal, resonance good over both lungs. There was a circular contused wound, three-quarters of an inch in diameter, and half an inch deep, with charred edges, at the junction of the sternum and ensiform cartilage. Another superficial burn (third degree) about 8 inches square over the front of the right chest, and several smaller ones. On the 12th day a deep slough came away, and air could be heard entering and leaving through the wound with each expiration and inspiration. Moist sounds could be heard all over both lungs. October 25th dulness was noticed over the right base, becoming more extended the day following. For the next month the wound discharged freely. On March 9th, 1883, he left the hospital cured.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 11TH.

Sir ANDREW CLARK, Bart., M.D., President, in the chair.

Dr. J. KINGSTON FOWLER read notes of a case of
SUBCUTANEOUS NODULES OCCURRING IN AN ADULT NOT THE
SUBJECT OF RHEUMATISM.

The patient was a man, *æt* 35, a railway porter, who came as an out-patient to the Middlesex Hospital, on Oct. 26, 1883, complaining of loss of appetite, pain in the epigastrium after taking food, and emaciation. There was no history in the family of syphilis, gout, or rheumatism. He had been fifteen years in the 2nd Life Guards without being in hospital a day. When 25, he had gonorrhoea, and a sore on the glans penis, the latter was probably not specific. Three years ago, he first noticed a lump beneath the right patella, it was then small and slightly tender. This gradually increased in size, the tenderness soon disappearing. About one month later a similar swelling appeared beneath the left patella, and gradually increased in size. Nodules appeared beneath the elbows shortly after. These remained, but no fresh ones appeared until four months ago, when he discovered a small one near the right

trochanter major; it was tender—and is so still—to a slight degree. This disappeared in a few weeks, but reappeared after an interval of one month, and has since grown steadily. Shortly after this second appearance a similar nodule was noticed near the left trochanter major. Similar growths have since appeared over the buttocks. On close examination as to any history of rheumatism the only fact bearing upon it elicited was that for the last two years he has had occasional pain about the knees after working hard, and then resting; the pain would occur perhaps two or three times a week. For the last six weeks he has complained of almost complete loss of appetite, with pain after food, and constipation. He has lost a stone and a half in weight. The nodules are arranged with almost perfect symmetry, and present the following general characters:—They are subcutaneous, nearly all are separable from the skin and from the subjacent structures, and are freely movable. The skin overlying and around them is normal. They occur singly, and also in large clusters, some of the large masses consisting of congeries of smaller ones. The single nodules are hard and shot-like to the touch, the larger masses are lobulated, and not so firm. They are not painful, but one near the right trochanter major is slightly tender. The distribution of these growths is as follows:—*Right arm*—On the posterior surface of the ulna three nodules situated about two inches from the olecranon, one as large as an olive, the others the size of peas. *Left arm*—Two nodules in like position, and of about the same size. *Ischial tuberosities*—Beneath the skin, which in the sitting position overlies the ischial tuberosities, there are on the right side six nodules forming a single mass the size of a tangerine orange—a rather smaller nodule is present on the corresponding spot on the opposite side. *Great trochanters*—Two inches below, and a little behind the right trochanter major, there are two collections of nodules forming a ridge about equal in size to a walnut; on the left side there are two smaller masses. Below each patella there is a nodule the size of a walnut. A small nodule is present below the internal condyle of the right femur, and another over the anterior surface of the right tibia. Reference was made to the original communication of Drs. Barlow and Warner, describing the occurrence of subcutaneous nodules, similar in many respects to those found in this case, in children and adolescents the subjects of rheumatism, and also to the cases of two adults related by Dr. Stephen Mackenzie, and Dr. Dyce Duckworth in the last volume of the Society's Transactions. It was pointed out that in the situation, symmetrical arrangement, free mobility, absence of pain or infiltration of overlying integument, these growths were similar to those found in association with rheumatism, and also that the situation of the growths had probably been determined by the irritant effects of pressure. Further experience may prove that they occur under a variety of conditions which have hitherto been overlooked.

Dr. DYCE DUCKWORTH remarked on the resemblance of the case narrated to one he had described during the last session of the Society. He had seen cases of subcutaneous nodules before the paper of Drs. Barlow and Warner was communicated to the International Medical Congress, and occurring in rheumatic subjects. His experience led him to think there were several kinds of such cases of nodules, the growths varying in position, and in size and consistence. In adults they presented a firmer feel than in children, and were persistent, while in the latter they showed a tendency to disappear, so that removal of the structures in grown persons by any other means than excision could not be hoped for. In adults also the rheumatic history was of the vaguest kind, while the cardiac affections observed in children did not accompany the presence of nodules on their bodies.

Dr. BARLOW said he would no longer assert dogmatically the rheumatic nature of the nodules. Gouty nodules resembled them very much, but were found to contain urate of soda when examined. He narrated the case of a young man, *æt* 25, of rheumatic tendency, on whom nodules were found, and who presented no cardiac lesion. Salicylate of soda was administered in gradually-increasing doses, and at first the nodules slightly increased in size, a cardiac murmur meanwhile slowly developing, and after six or eight months the nodules had completely disappeared. He had lately observed that small nodules were amenable to treatment by blistering.

Dr. MAHOMED gave a brief history of a woman *æt* 35, the subject of well-marked nodules. She had no cardiac murmur. Twenty grains of salicylate were given three

(a) From notes of the case read at the Sheffield Medico-Chirurgical Society, December 30th.

times daily, and in a fortnight the nodules entirely disappeared. He wished to know in what proportion of rheumatic patients the nodules occurred. He had seen but two cases in as many years.

Dr. GLOVER stated that he had seen a case in which nodules developed in a young man slowly recovering from rheumatic fever. The growths ultimately disappeared.

Mr. PARKER wished to know in what situation the gouty nodules mentioned by Dr. Barlow had been found. He had himself seen cases of subacute rheumatism in which the nodules occurred quite superficially in front of fasciae.

Dr. R. LEE instanced the case of a child afflicted with chorea, the movements being almost confined to the right side of the body, which also was alone the seat of a number of subcutaneous nodules. Subsequently, however, after two or three months, they were found on the left side also.

Mr. CLEMENT LUCAS observed that it was of great interest to know how far the nodules were characteristic of rheumatism. In the case of a woman under his own care, nodules developed on the knees and elbows, and interfered with the power of kneeling. They underwent no absorption when treated, and were excised, and found to consist of fibrous tissue. No history, family or personal, of rheumatism was obtainable. About the same time a student of Guy's Hospital who was laid up with rheumatism became the subject of subcutaneous nodules.

Dr. GILBERT SMITH had seen two examples of undoubted nodules in women; and he regarded the mortality among children in whom they occurred as less than was thought to be the case.

Dr. ANGEL MONEY thought from his experience, gained at the Children's Hospital, that fifty per cent. of rheumatic children became subject to nodules. In one case, which presented a multitude of growths, they would appear and disappear within a few days, and in different parts of the body. He had found serious heart disease in two of the cases examined *post mortem*.

Dr. FOWLER explained that the nodules occurred on points which were subjected to pressure, and were therefore probably due to irritation.

Dr. COXWELL on a case of

CORTICAL TUMOUR, WITH GREAT VARIETY AND FREQUENCY OF EPILEPTIFORM SEIZURES.

Ten years ago, G. R., a young man, then *æt.* 20, began to suffer from fits, which always had as their starting point the right hand, and never had a greater range than the right arm and right side of the face. Five years later he came under the care of Dr. Gowers at the National Hospital for the Paralyzed and Epileptic. He was admitted as an in-patient for the last time in February, 1882, under Dr. Radcliffe, who kindly permitted the publication of the case. He then had optic neuritis in the left eye, but not in the right. There was some paralysis of the right arm and right leg, but none of the face. The deep reflexes were all in excess on the right side, with right foot clonus. Dr. Coxwell during eleven months was enabled to make careful observation of the mode of onset of many of his epileptiform seizures. When the fits were frequent, an hour spent at his bedside was rewarded by a view of several fits. As the time was summer, he could lay without danger with his limbs uncovered, and if they were placed in a position of semi-flexion or semi-abduction, as the case might require, the slightest initial movement could not fail to attract attention. In the numerous cases of cortical tumour which have been recorded the fits have nearly invariably been described as beginning in the same place. In this case, however, during the last year of the patient's life there was great variety in the starting place and range of the fits. The patient died in January, 1883. A large number of Dr. Hughlings Jackson's statements with regard to epileptiform seizures were exemplified in this case. Mention, for instance, was made of temporary paralysis of right side of face, or of right arm, caused by fits affecting those parts; of the connection between the occurrence of aphasia and fits affecting the right side of the face; of the fact that when spasm spreads from the first affected side to the other, it passes to the leg of the second side and not to the arm or face. The patient had every variety of fit, including some of the ordinary epileptic type, characterised by sudden loss of consciousness and general convulsion. It had been stated that these fits do not occur in such cases; perhaps the greater and widely spread instability which this kind of fit implies was

the result of the extraordinary frequency of the fits, and the great duration of the case (ten years). There was a tendency at different times for some special type of fit to occur, sometimes the face alone being affected, sometimes chiefly the right arm, sometimes the whole of the right side, and so on. Perhaps the explanation was that the tumour created instability in cortical areas adjacent to that in which there were pathological changes, and that when the instability reached a certain degree of intensity, explosive discharges occurred in them, causing spasm in corresponding sets of muscles. The spasm having attacked the arm, nearly invariably proceeded upwards—extremely seldom downwards. One never saw a twitch at one joint—say the elbow—then a twitch at the knee, and then at the mouth. In each case, on the contrary, there was a definite line of march of the spasm, either up or down a limb. These facts seemed well explained by the localisation theory. The tumour was found at the autopsy to be a glioma affecting the posterior parts of the first and second frontal convolutions, and the extreme summits of the ascending frontal and parietal convolutions on the left side. Its position therefore corresponded very fairly with what one would have expected, from the fact that during the first nine years of his illness the spasm always commenced in the right hand. This man often had 200 or 300 fits a day. In the last year of his life, 21,800 fits were counted.

Dr. BRAVER, who had seen the case in 1882, corroborated the statement that the fits all began on the right side. He had tried to localise the seat of the lesion by percussing the skull, and had found a spot of tenderness corresponding to the situation of the lesion described after death. On the right side he had demonstrated diminished cremasteric and abdominal reflexes. As the result of examining 70 cases of ordinary epilepsy he found that in them, after the fits, ankle clonus was temporarily increased, while the plantar reflexes were diminished. He described three classes of epilepsy, all due to cortical lesions.

Dr. GLOVER asked if the patient injured himself during any of the fits he experienced?

Dr. COXWELL replied to Dr. Glover's question in the negative, giving as reasons the fact that the patient preserved consciousness during the fits at first, and subsequently when they grew worse in character, he was carefully guarded in hospital. He had himself detected the tender point referred to by Dr. Beaver.

ACADEMY OF MEDICINE IN IRELAND.

OBSTETRICAL SECTION.

At the opening meeting, held at the College of Physicians, Dr. G. H. KIDD, President, occupied the chair.

Dr. W. C. NEVILLE, Sectional Secretary, read the minutes, which were signed.

THE PRESIDENT'S ADDRESS.

The PRESIDENT expressed his thanks for the honour paid him in electing him as President of the Obstetrical Section, the work of which during the past session he reviewed.

SUB-MUCOUS FIBROID TUMOUR.

Dr. ATTHILL exhibited a sub-mucous fibroid tumour, globular in shape, almost the size of a turkey's egg, which he had removed from the uterus of an unmarried lady, *æt.* 35. The patient had suffered for more than two years from constantly recurring uterine hæmorrhage, which had of late become almost continuous and accompanied with great pain. She consented only to a local examination when reduced to an extremely feeble condition. The uterus was then found to be completely filled by the tumour exhibited, which had been removed by the cræseur, after dilating the cervix. The tumour was attached by a wide base to the fundus, but examination after its removal showed that it had been separated from the uterine wall by a distinct capsule, its connection with the uterus being maintained by a thin investiture of the proper muscular tissue of the uterus and of the mucous membrane which had become stretched over it during its extrusion from the uterine wall. Dr. Atthill emphasised the point that this was not therefore a polypus, properly so-called, which should consist of a continuous outgrowth of uterine tissue. There would be no difficulty in tracing the continuity of the uterine muscle into the substance of a true myomatous polypus, while the presence of a capsule causing discontinuity was characteristic of a true fibro-myomatous tumour. This

distinction had been drawn by Paget, but had not been sufficiently attended to in current works.

Dr. MACAN and the PRESIDENT dissented from the definition of a polypus as laid down by Dr. Atthill. They understood by a polypus a tumour possessing a pedicle, other considerations being immaterial and having no effect on treatment.

UTERINE POLYPUS.

Dr. MACAN exhibited a large uterine polypus which he had removed from the vagina of an unmarried woman, *æt.* 45, who had suffered severely from hæmorrhage for twelve years. The tumour had passed into the vagina, being connected with the uterus by a very thin pedicle which, however, bled very profusely on being cut across by the *écraseur*. The size of the tumour, the great length of the vagina, and the rigidity of the external parts, made the removal of the tumour very difficult, and in effecting it a rupture of the posterior vaginal wall into the rectum had occurred. The rent had then to be stitched, and the patient was doing well.

Dr. ATTHILL observed that this case was an exception to the rule that polypi when they had become vaginal rarely caused much hæmorrhage.

Dr. MACSWINEY inquired whether means might not have been employed to lessen the size of the tumour and so lessen the risk of vaginal rupture.

Dr. HORNE observed that multiple incisions of the tumour had been successfully used to effect this purpose in similar cases.

Dr. MACAN replied that in his patient the profuse hæmorrhage which had followed the division of the pedicle had made it necessary to remove the tumour more rapidly than would otherwise have been desirable.

MACERATED TWIN FÆTUS.

Dr. MACAN exhibited a macerated fœtus which must have died about the sixth month of a twin pregnancy, the other twin continuing to develop until term. The surviving child, weighing seven pounds, was delivered naturally. Considerable hæmorrhage ensued, and after the birth of the first placenta a degenerated placenta surrounding the second child followed.

Dr. PUREFOY mentioned a similar case which had occurred in the Coombe Hospital.

CHRONIC INVERSION OF THE UTERUS.

Dr. MACAN showed the fundus of a uterus which had become inverted nineteen years ago, after the only labour of a woman now aged 41. Since then she had suffered from severe hæmorrhagia, and had been lately treated by pessaries for prolapse. The upper portion of the vagina was extremely narrow, and the vagina itself so rigid as to preclude the possibility of introducing a hand. He therefore determined on amputating the uterus, bringing the edges of the stump together by a number of sutures after the method advocated by him for the first time some years since in a paper read before the Dublin Obstetrical Society. The patient was able to walk about a week after the operation, her temperature never having exceeded normal limits.

Dr. ATTHILL had found attempts to replace recently inverted uteri very dangerous, their tissues were so soft and lacerable. In one such case his fingers had gone right through the walls of the inverted uterus. When of long standing the inversion could be more safely treated; but reinversion might then prove of no great use. Amputation properly performed was certainly less dangerous than prolonged and forcible efforts at reduction.

The PRESIDENT had frequently practised the operation as described by Dr. Macan, introducing the ligatures first, then amputating with the *écraseur*, and finally bringing the surfaces of the stump together. He had never seen ill effects follow such an operation.

INDUCTION OF PREMATURE LABOUR.

Dr. PUREFOY read a paper on the induction of premature labour, illustrated by three successful cases. Having sketched the early history of the operation and the various methods employed, the author specified three classes of cases in which the induction of premature labour was indicated. Firstly, in the cases of women with pelvis so narrow that the passage of a living, full-timed child is impossible, whilst an undeveloped yet viable child might safely be delivered. Secondly, where several previous successive pregnancies had been interrupted at a certain period by the children's death. Thirdly, where the women suffer from morbid conditions likely to disappear

or become greatly mitigated by delivery. Difficulties arise in practice owing to doubts as to the exact period of pregnancy, and as to the true amount of pelvic deformity. The presence of deformity increased the difficulty of fixing the period of pregnancy, while the patient's own calculations are unreliable. The size of the child's head must be assumed from that of its known averages at different periods of gestation, while the available pelvic space must be carefully measured, as is often necessary by the introduction of the entire hand into the vagina. In many cases the conjugate of the brim being the diameter mostly if not entirely at fault, it will then suffice to measure this accurately. It is impossible to define narrowly the amount of pelvic deformity to which this procedure is applicable. But its extreme limit may roughly be stated to have been reached when the true conjugate diameter measures 2.75 inches. Dr. Purefoy then narrated the history of three successive labours induced at the eighth month in a woman with a generally contracted pelvis, whose first labour had only been concluded by a difficult cephalotripsy, subsequently succeeded by a considerable amount of vaginal alounging. The method adopted on each occasion consisted in the passage of a white elastic catheter between the uterus and the membranes supplemented by the use of Barnes' bags. Delivery by forceps in each case resulted well for the mother and child. The author concluded that it is necessary for the certain efficacy of Kransen's method that the catheter should be so introduced as to reach the fundus uteri, otherwise contraction might fail to be set up. Caution must be exercised to avoid wounding the placental attachment. On each occasion he had found vaginal dilatation of much service in keeping up the uterine action. He did not doubt that the children's lives had been saved by the early application of the forceps, and before the os had been fully dilated.

Dr. MACAN held that the chief danger in the catheter method consisted in the possible introduction of septic material into the uterus, against which every precaution should be taken.

Dr. ATTHILL could not regard the operation as an entirely safe one, having lost two out of five patients on whom he had performed it. The great danger was septicæmia. He had originally pointed out that the catheter must reach the fundus in order certainly to bring on labour.

Dr. SMYLY remarked on the great difficulty of determining the size of the fœtus. Reliance could not be placed on the fact that craniotomy had been performed during two or three of the patient's previous labours. He considered a bougie much safer than a catheter, the latter affording a ready channel for the passage of air and septic material into the uterus.

Dr. NEVILLE had assisted the President in three cases of induction of premature labour. The catheter alone had sufficed in each case to bring on labour quickly and quite successfully. He would by preference employ a bougie, and of course take every antiseptic precaution. All things considered he believed Kransen's the safest method of inducing labour, and in his experience it had also been very speedy.

Dr. HORNE had induced labour in two instances by this method; but one of the patients subsequently died of septicæmia.

The PRESIDENT having, he believed, tried most methods, held that the one under discussion was the best; rupture of the membrane being next best, though not so safe for the child. If the case were one that did not admit of delay, he would employ Barnes' bags. He did not consider it essential that the catheter should reach the fundus, as in cases in which it had acted quite perfectly, he concluded from its spiral shape on withdrawal that it had passed round the uterus between its lower segment and the membranes. He had only once used a stilette, and always softened the catheter well before using it. Labour usually came on within twelve hours.

Dr. PUREFOY replied briefly; and
The Section then adjourned.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, DECEMBER 20TH, 1883.

H. F. BANHAM, M.D., PRESIDENT, in the Chair.

BELL'S PALSY WITH CONTRACTION OF MUSCLES.

Dr. BANHAM gave the notes of a case of Bell's paralysis,

which was either of the rheumatic form, or due to syphilitic neuritis, and which was followed after some months by contraction of the facial muscles, impaired movement of the left palate, and distortion of the uvula. It was pointed out that a neuritis of the facial nerve external to the Fallopian tube was less likely to produce a destructive compression of the nerve and subsequent degeneration and contraction of muscles than the same amount of inflammation taking place within the unyielding bony canal. There was evidence in this case that the inflammation had extended upwards to the geniculate ganglion. Attention was drawn to the fact that the muscles were not spasmodically contracted, but had undergone atrophic contraction, and any efforts to extend them gave rise to acute pain.

Dr. BANHAM also gave particulars of a case of

PROGRESSIVE UNILATERAL ATROPHY OF THE FACE.

The patient was a strong and otherwise healthy girl, of 15 years of age, her father and one of her sisters had suffered from neuralgia, but the family did not, with this exception, show any tendency to any disorders of the nervous system. Four years ago she had a bad gumboil connected with a carious bicuspid of the right side of the lower jaw. In a day or two, the face meanwhile being considerably swollen, the gumboil burst and freely discharged. The tooth was subsequently extracted. With the exception of the diseases of childhood she has always enjoyed perfect health. Shortly after the gumboil trouble she began to experience tenderness about the right side of the neck and face, and also especially about the ear. This condition has continued nearly to the present time. Two years ago the parents noticed some wasting of the face which, it occurred to them, might be connected in some way with the old gumboil. There was also some little discolouration about the skin of the right side of the neck. At the present time there is marked wasting of the right side of the face, below and in front of the ear is a considerable depression, apparently giving one the idea that the parotid gland, and the upper part of the masseter muscle are greatly wasted. On the right side of the neck and over the sterno-mastoid muscle the skin is dry, and has apparently lost its subcutaneous fat. It can be readily raised from the subcutaneous tissue and imparts to the fingers the feeling very much of thin flannel. It has a discoloured dirty appearance. Sensation, masticatory power, and blood-vessels are normal. The possible connection of the gumboil with the present symptoms from an ascending neuritis was alluded to. Attention was also drawn to the fact that in this case the wasting was probably entirely of fat and connective tissue.

SUPPOSED CANCER OF THE LUNG.

The following case was related by Mr. E. SKINNER:—"Mrs. H—, æt. 21, sent for me on March 19th, 1883. She came then suffering from cough with consolidation of the left apex, and all the symptoms of phthisis. I saw her from time to time up to March 28th, she then went into the infirmary. I next saw her in July when she was suffering from hæmoptysis, and attended her until August 1st, she then, I believe, became an out-patient at the hospital. I saw her again on November 1st, she was spitting blood, the voice was very husky, and she was unable to lie down. The dulness had increased very much, and she was complaining of great pain in the left shoulder. In a few days the left arm became very oedematous, and afterwards the other, there being no oedema of the lower extremities. I then came to the conclusion that the case was one of cancer of the lung. She died on the 6th of December. *Post-mortem*, December 5th—The left lung was one solid mass of white matter. It was adherent to the chest walls. The other lung appeared quite healthy. The liver was very large.

Dr. DYSON read a paper on

SOME DIFFICULTIES MET WITH IN THE EMPLOYMENT OF
BEST AS A THERAPEUTIC AGENT IN MEDICAL CASES,
which will be found on page 43.

In the discussion that followed Drs. Law, Martin, Thomas, Porter, Messrs. Browning, Walker, Reckless, and the President (Dr. Banham) took part.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 8s. 6d. per annum.

SUBSCRIPTIONS FOR RUSSIA are received by Messrs. RAJCHMAN and FREUNDLER, 18 Senatoren Street, Warsaw—post free £1 4s. 0d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York by Messrs. WILLMER and ROGERS; Philadelphia, by Dr. BRIGHTON: post free in advance, 5s. dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-Office Order.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 16, 1884.

PSOAS ABSCESS AND SPINAL CARIES.

At the Royal Medical and Chirurgical Society, on Tuesday evening, the 8th inst., Mr. Frederick Treves described the operation devised by him for the purpose of direct evacuation of pus collected about the bodies of the lumbar and last dorsal vertebrae, and for removal of diseased bone when found in this situation. The question is one of such importance that the time of the whole meeting was very properly devoted to its consideration; and lengthy discussion was given by several of the leading authorities in surgery to the paper in which Mr. Treves communicated his results.

The gravity of such cases depends, as Mr. Treves pointed out, principally on the depth at which the disease is situated, rather than on any special pathological feature in the process, the usual procedures applied elsewhere to caries being precluded by the circumstances surrounding its presence in and about the vertebral bodies. The necessity thus produced of providing distant openings by which pus may be removed, is one of the worst features attending the ordinary operation for relief; and should the course followed by Mr. Treves result in frequent adoption of his method in suitable cases, he will have been the means of affording

needed benefit to a large class of sufferers in the future. By the operation proposed, a vertical incision is first made near the outer edge of the erector spinæ muscle, and the sheath of this and of the quadratus lumborum next cut through. The vertebræ are then reached by incising the psoas, and following the structures on to the surface of bone. Ready examination of the vertebræ is thus rendered possible; and should sequestra exist, their removal is rendered perfectly easy, as occurred in the first case to which Mr. Treves applied the proceeding. This and two other patients who subsequently underwent the operation, did well as far as the operation itself was concerned, although one, a boy, subsequently succumbed to pre-existent chronic lung disease and other mischief.

It is, of course, a matter of opinion how far the plan proposed can be applied in practice; but that much advantage must accrue to the patient in every case where free vent can be given to pus, and its evacuation encouraged at the point most favourable to its escape, is sufficiently evident; doubt first creeps in when consideration is had to the possibilities of discovering whether or not the conditions are favourable to it. In Mr. Barwell's opinion the condition of caries of the spine accessible to such an operation must always be occult to the surgeon, since he could never ascertain by external examination whether he was called upon to deal with a single sequestrum or an extensive carious surface. In those patients, like strumous children, where this was considerable, it could not be anticipated that entire removal of the mass would be feasible; nor could it be suggested for a moment that measures applicable to superficial caries were here admissible. This objection is one that will find general acceptance; and, indeed, Mr. Treves himself intimates his agreement with it; but, at the same time, he is justified in contending that nothing short of actual examination of the part can determine the nature of the mischief present, and enable appropriate treatment to be applied to such cases as, e.g., in the first he records, are specially fitted for successful operation.

Mr. Bryant lends approval to the manner in which Mr. Treves has brought the treatment of spinal disease under general surgical principles; and, while urging that it can lead to removal of bone in but a limited number of instances, he points out the distinct advantage it possesses for giving the benefits of early and efficient treatment to psoas and lumbar abscesses originating independently of caries, and leading to it by subsequent extension to the bone. In his own experience, Mr. Bryant had treated cases of abscess about the spine on the principle advocated by Mr. Treves—viz., free drainage; and in two he had removed sequestra from the crest of the ilium; three others failed to present any diseased bone for removal.

It is not, however, to be assumed that Mr. Bryant expresses the general opinion of surgeons in yielding approval to the operation, for Mr. Savory does not admit that sufficient exposure of the parts in the region concerned can be secured by it to allow examination and treatment to be carried out with success. Moreover, he regards the operation itself, when fully performed, to be

inadequate to the end held in view; and as an exploratory measure he holds the proceeding unjustifiable, especially since the presence of sequestra cannot be foretold by the surgeon.

The discussion to which we have thus briefly alluded carries many important lessons, and is fruitful of suggestion. It indicates very clearly the existence of dissatisfaction with methods now in use for treatment of large abscesses about the vertebræ; it shows, further, a readiness on the part of many to hail any proceeding which holds out promise of more successful results in the future; and, above all, it has afforded demonstration of the fact that old-time limitations of procedure no longer have power to retard advance. Such operations as that Mr. Treves proposes are no longer to be ranked among the improprieties of surgery; the application of Listerism during their performance, deprives them of the first element of danger; and it may be inquired, with the author of the paper in question, whether it is more serious to make a simple exploratory incision down to the spine, under antiseptic precautions, or to leave a case of uncertain bone disease quietly to develope until its presence can be no longer matter of doubt. Indeed, it may be inferred from the general tenour of the discussion on the paper that a first consideration in the future will be to convert doubt at the outset into positive certainty; and, by providing early for the ready escape of puriform material, to delay and prevent the further development of that disease, to the progress of which all the evils attendant on caries of the spine owe their origin.

Mr. Treves is a bold surgeon, but to the boldness of the operator he unites the caution of the careful thinker; and his applications of anatomical principles to surgical practice enable him to make valuable suggestions in aid of progress. By adding an additional means of limiting the disasters attending the presence of large abscesses in deep-seated parts of the body, he increases the resources of surgical art; and, even though the numbers who agree to follow him may be small at first, yet, as the results obtained grow in extent, so will confidence in a bolder proceeding develope.

THE SCOTCH CORPORATIONS AND IMPENDING LEGISLATION.

FOR the last few months active measures have been taken by the Corporations to prepare for the coming struggle with the Government. Frequent meetings have been held; anxious and *impromptu* discussions at the corners of the streets have not been infrequent; and a restless desire to do something is evinced on all sides. In a few weeks all will be in readiness, and a perfect mine be laid for the complete annihilation of the "busybodies of London," as Professor Rutherford calls those whose desire it is to see the licensing system of the kingdom put on a sounder and fairer basis than at present exists. If we can judge from the rumours now afloat, the Corporations have decided to discontinue granting their separate qualifications and to combine to give only a double qualification. This amicable arrange-

ment is to remain in force for five years, when any one of the contracting parties may withdraw from the union and will then be at liberty to proceed as it pleases. From this, one of two things must happen, either the slow but certain annihilation of the Glasgow Faculty or a return to the present state of affairs. It is scarcely probable that a candidate will select the diploma of the Glasgow Faculty when the Edinburgh can be obtained on the same terms; and it is morally certain that the Edinburgh College will not submit to a loss of fees, which must result, without receiving something in return. But even admitting this arrangement to work amicably as far as the contracting parties are concerned, what guarantee will the Government have that the standard of medical education and examination will be improved and maintained? The examinations of the Corporations are conducted in a most secret manner, and it is only by stealth that the questions set at the written part of the examinations are made public. Certain persons are, it is true, appointed as Assessors, but these are carefully selected by the Corporations themselves and not by the Government; and we have no record of their being ever present at any of the examinations. At present, also some of the examiners are elected for life; some have been in possession of the post for twenty or more years. This state of matters is neither fair to the student nor of advantage to the profession, and it is absurd that candidates should be taught the principles of modern medical science and examined by men whose generation has ceased to exist except in a more or less fossilised condition. There was in the last Medical Bill a weakness which Mr. Mundella and those in charge of renewed medical legislation should be prepared to remove. It will be remembered that it was proposed that the Corporations should be permitted to examine on the primary subjects of medical education the Government only superintending the final examination. In other words, the examinations on anatomy, physiology, and chemistry, the tripod on which all medical science is built, were to be left to the Corporations and Universities. As far as the Corporations are concerned, no one who knows the peculiar views of some of the heads of these institutions would have sanctioned such a proposal. Not long ago it was gravely asserted in one of the Corporations that all the chemistry that should be required of a candidate might be obtained from a school course, and the examination in which should form a part of the preliminary examination in Arts. It is needless to say that at present chemistry is not taught in schools, and that considerable alterations would have to be made in school education before it could be taught, and even then only a most inadequate acquaintance with the science could be obtained. The Government proposal would further tend to deteriorate the teaching of the primary subjects of medical education, and foster a most superficial acquaintance with the fundamental sciences of medicine. To allow the Corporations to have anything to do with the examinations, except under the most vigilant supervision, would be most detrimental to medical reform. Candidates would, as now, select the Corporation where the easiest primary could be ob-

tained. It is difficult for anyone outside the shadow of the Corporations to see what claim they have to any consideration from the Government. They are not teaching bodies, and they take only the most slender interest in the medical schools which surround them. They do nothing to advance medical science either by grants for original research, by lectureships which might be held with honour, or by prizes which would tend to foster a healthy and honourable competition among the younger members of the profession. To procure candidates, and to invest the fees obtained from them in sound securities has been, and is, the one idea which permeates the whole life of the Scotch Corporations.

PROFESSIONAL SYMPATHY.

"'Tis an ill wind that blows no one any good" is a trite saying that was never more fully exemplified than in the Bower and Keates case, of which the profession has heard so much during the past few weeks. It will be fresh in the minds of our readers that in October last Dr. Bower and Mr. Keates, partners in general practice at Peckham, were charged before the Lambeth magistrate with manslaughter, on the application of a man whose child died after tracheotomy performed by Dr. Bower. The case was first seen by Mr. Keates, who diagnosed croup; the child grew rapidly worse, and Dr. Bower being called to see it in consultation with his partner, promptly performed tracheotomy, instant relief to urgent symptoms ensuing. Soon after the operation was completed, however, an obstruction in the tube threatened suffocation of the patient, and the father thereupon sucked out the occluding membrane, at once ejecting it from his mouth. The child succumbed on the Monday—two days after, and on the Thursday following the father showed symptoms of diphtheria; but after going through an attack of this disease he recovered without secondary complications. He thereupon brought—firstly, an action for damages; and, secondly, one for manslaughter against the medical attendants, in both of which he was unsuccessful. In their defence these gentlemen incurred nearly £1,000 expenses, and, as the case was one of considerable hardship, to which any one in practice might be exposed, a meeting of the profession was called at the house of Sir William Jenner, and an appeal subsequently issued with the object of defraying the costs to which Dr. Bower and Mr. Keates had been put. This appeal met with such a ready and unanimous response that a much larger sum was subscribed than was required, and the question is uppermost, What is to be done with the surplus? Some of the contributors write that they understood that the fund was designed, not only to meet the present case, but as a subsidy or nucleus for a permanent defence fund, to assist others in their defence when attacked by an ignorant or malicious patient. Such an object would have the entire sympathy of the profession; but the difficulties in the way of its application are much greater than would appear at first sight, but which will readily occur to thinking men. We trust, however, the Committee ere it separate will take

the matter into earnest deliberation ; a hasty refusal to adopt that which to a large number seems a reasonable proposal would undoubtedly damp the ardour of present contributors, if unfortunately a similar occasion again arose for an appeal. Criminal charges initiated against medical men, it is true, are extremely few, and those grounded on truthful bases are among the least familiar to readers of law reports ; but the year 1883 will be notorious for three prominent cases, the charge in each having failed, but with such sad results as will long dwell in the memories of the present generation, and show the necessity for united action of some kind in its own defence. But Dr. Bower and Mr. Keates are to be congratulated, not only on the successful result of their action and the payment of their costs by the profession, but also upon the success of another fund, which will, we doubt not, afford them equal pleasure. We refer to a testimonial fund raised by their patients and neighbours and presented to them yesterday (Tuesday) at a crowded and enthusiastic meeting at Peckham. In November last an early meeting was held, under the presidency of the vicar (the Rev. Dr. Warburton), at which it was decided that some tangible proof of their sympathy should be given to those gentlemen, as a result of which a sum of about 150 guineas was readily contributed by 131 subscribers, whilst patients and friends vied with neighbouring practitioners in evincing their sympathy and unabated confidence. Thus this first fund—started before the profession had met to decide upon a course—was happily ended yesterday by the presentation of a silver salver each to Dr. Bower and Mr. Keates, a purse of 100 guineas, and an illuminated address, expressive of the esteem in which they are held in the neighbourhood, and in condemnation of the attack to which they were subjected. The committee, whose names we are happy to place on record (Mr. Loris Schlesniger, Treasurer, Messrs. Brown, Birt, Grimsell, Owen, Kelham, Charlton, Leyfang, and Watts), have been indefatigable in their exertions, and with the recipients are to be congratulated on the result.

Notes on Current Topics.

Death of Mr. Wheatley.

We regret to announce the death of Mr. B. R. Wheatley, Resident Librarian to the Royal Medico-Chirurgical Society, which occurred almost suddenly on Wednesday last. By his invariable courtesy, and willingness to afford the assistance his large acquaintance with medical literature enabled him to give to those engaged in original work, Mr. Wheatley had gained the respect and esteem of a very large proportion of the profession ; and many will be grieved to learn that his cheerful, unobtrusive presence will no longer be met with in the institution which for a long number of years has been his home. It is natural that the event should have been referred to at the first Society meeting occurring after it ; and on Friday evening both Sir Andrew Clark, President, and Mr. Christopher Heath, Treasurer of the Clinical Society, took occasion to speak in feeling terms of the loss sustained by the Society

in Mr. Wheatley's death. Though not an actual officer of the Society, the deceased was nevertheless an active assistant in all relating to its business details ; and how sincere a feeling of esteem his many good qualities have engendered in those who have been in any way directly associated with him, was demonstrated by Sir Andrew Clark's generous and graceful testimony to the dead man's worth. For twenty-five years, Sir Andrew said, he had known Mr. Wheatley, and ever had he found him an upright man, the word thus used being designedly introduced for its very expressiveness. For ourselves, also, we gratefully echo this tribute to a character that deserves most kindly memories, for Mr. Wheatley has often lent us much assistance—always rendered, too, with perfect willingness and readiness—in the promotion of our labours in connection with the Clinical Society's meetings. As a librarian he possessed qualities that can scarcely be expected in his successor, for to business tact and administrative ability he united a knowledge of books such as is found only in those who bring to their special work an earnest interest in it, and a determination to be "thorough." The funeral took place yesterday at Highgate, and was attended by a considerable number of members of the various societies which hold their meetings at the rooms of the Medical and Chirurgical Society.

Treatment of Wens by Ether Injections.

A COMMUNICATION to the *Bulletin Générale de Thérapeutique*, by Dr. Lemoyez, discusses the different methods of treatment of sebaceous cysts of the face and scalp, and recommends parenchymatous injections of pure sulphuric ether. A case is reported of a man who was relieved of a wen of five years' growth by ten hypodermic injections of ether practised at intervals of a day or two. The result was the conversion of the tumour into a cyst with fluid contents, the evacuation of the same, and speedy destruction of the cyst-wall by inflammatory action. In the case quoted, the treatment resulted in a perfect cure in a month, without keeping the patient in bed or restricting his movements as would have been required by the ordinary operation.

The advantages claimed for this method are its simplicity, painlessness, and efficiency, without exposing the patient to the risk of a surgical operation or in any way interfering with his business. The injections are made into the interior of the cyst, five or ten drops at each sitting, the needle of the hypodermic syringe being moved about so as to break up the contents as much as possible. They are discontinued when inflammation or suppuration begins.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow :—Calcutta 25, Bombay 24, Madras 36, Paris 24, Geneva 22, Brussels 22, Amsterdam 30, Rotterdam 29, The Hague 28, Copenhagen 21, Stockholm 22, Christiania 22, St. Petersburg 31, Berlin 22, Hamburg 24, Dresden 26, Breslau 30, Munich 28, Vienna 24, Prague 34, Buda-Pesth 25, Trieste 36, Rome 25, Venice 27, Lisbon 33, New York 23, Brooklyn 18, Philadelphia 20, and Baltimore 18.

The Olinical Society of London.

THE annual meeting of this Society was held on Friday evening last, Sir Andrew Clark, Bart, presiding, when, in addition to the usual business, elsewhere reported, office-holders for the ensuing twelve months were elected. The names of gentlemen on whom the choice of the Society fell will be found in the list published in our columns last week, all the candidates nominated by the Council having been unanimously elected. At the conclusion of the meeting, Mr. Pearce Gould gave a demonstration on the employment of the endoscope for urethral examination, the illuminant being an electric lamp. For the purpose of the exhibition two patients were introduced, one the subject of gonorrhœa and the other presenting a normal urethra.

Iodoform and Calomel.

As this combination is often ordered by specialists as a dusting-powder, it may be of interest to know that the ingredients are, to a certain extent, incompatible. In a communication read before the New York College of Pharmacy, it is stated that iodoform and calomel are decomposed by light at an ordinary temperature.

Charlatan.

THE *Apotheker Zeitung* gives the origin of this word as follows:—In the olden time, when the doctors were not in the habit of riding about, their homes were hospitals, and they did not leave their patients. At that time a genius made his appearance in Paris. His name, was Latan. He procured a small one-horse wagon (*char*), upon which he packed his remedies for all possible affections. With these he drove through the streets of Paris, crying out his wares and looking for patients. He was the first driving doctor, and soon became renowned. Whenever he came along, the populace greeted him with, "Voilà le char de Latan." This was soon abbreviated to "Charlatan," which, at that time, denoted a driving doctor.

Vital Statistics of Vienna for 1882.

THIS report has just been published by Dr. W. Löwy. It gives the number of births during the year 1882 as 29,262: of this number 27,857 were those of living children, and 1,405 were still births; 15,085 were boys and 14,164 girls. In 13 the sex was not distinguishable. 16,605 were born in wedlock, and 12,657 were illegitimate. Compared with the previous year the total number of births had diminished by 1,165—equal to 3·8 per cent. The births of living children had diminished by 1,164—equal to 4 per cent., whilst the still births had only diminished by 1. The percentage of illegitimate births had fallen from 45·2 to 43·2 per cent. The births were 39·5 per 1,000, against 41·7 in 1881. The total number of deaths of registered persons was 21,595, 46 or ·2 per cent. more than in the previous year. Of the actual population of Vienna 18,722 died during the year, 133 or ·7 per cent. more than in 1881. The total deaths amounted to 29·2 per 1,000; whilst as regards the actual city population the number was 25·3 per 1,000. In the previous year the corresponding figures were 29·5 and 24·4. The natural increase of the population, i.e., the excess of births over deaths, was

9,135, or 1,292 less than in the previous year, and 701 less than the average of the years 1877 to 1881. It amounted to 13·7 per 1,000 of the population.

Co-operative Oppression.

It seems to be too readily assumed that the lot of *employés* at Co-operative Stores compares favourably with that of ordinary shop-assistants. One feature of the Store system which was supposed to give it superiority, is that those serving under it are relieved from the cruel oppression of immoderately long hours, and are so enabled to devote a sufficient portion of their lives to healthy recreation and necessary amusement. But from a correspondence now in progress in the *Standard* it appears that Co-operative Store managers are as guilty as private shop-keepers of imposing the burden of extra time and work on their subordinates; and this, too, without the compensation for health contained in additional pecuniary remuneration. Should the statements which have been made in this connection prove to be really founded on fact, there can be no question of the necessity that has arisen for investigation and improvement. The number of young men and women who find employment in the various Stores is very large: one such association includes more than fifteen hundred assistants; and it becomes a grave consideration how far the physical well-being of this body of workpeople is sacrificed in the interests of mere gain. Even on grounds of economy it is open to doubt whether more ill than good does not result from over-exaction in the way of labour, for when the working day is unduly extended the later hours must be largely unproductive as compared with those during which the *employés* are refreshed and invigorated after rest. From a medical point of view the subject is, however, a very important one, inasmuch as a good proportion of the persons concerned are actual or possible fathers and mothers, whose deteriorated physique is likely to produce an injurious effect on their offspring, and thus increase the amount of national weakness and sickness. Comfort and policy alike demand a searching inquiry into the real state of the case.

Strychnia as an Antidote to Chloral.

In the *Journal de Médecine de Paris* particulars were given of a case in which dangerous symptoms occurred in a man who had taken fifteen grains of chloral to produce sleep. He did not awaken in the morning; at 10 a.m. the whole body was cold; the heart frequent, weak, and irregular; respiration laboured; pupils not responding to the stimulation of light; and all reflex action had ceased. The power of swallowing was lost. Two hypodermic injections were given in the course of half-an-hour (1st dose—1½ mgr.; 2nd dose—2 mgr.). The heart's action improved after each dose, becoming more regular, slower, and with slight increase in the force of impulse. Four and a-half hours after another injection was given of 2 mgr., half-an-hour after which consciousness returned—the pulse beat 68 per minute, and was regular. In the evening he was able to walk a little, and next morning he travelled home some distance in a wagon. During the following night he took 35 grains of chloral, in spite of his recent experience, and died in two hours.

Water for Infants.

SOME two years ago Dr. Davis, of Chicago, called attention to the condition of the blood of infants in summer, which we might term *ex-aqueous*, due to the excessive amount of liquid lost by perspiration, and which he deemed predisposed the system to the summer diseases of children; and now Dr. Charles Remsen (*N. Y. Med. Jour.*) calls attention to this point, which has received altogether too little attention. We all know how seldom an infant is given any more water than that contained in its food, and yet we all see how eagerly they will often drink when it is offered to them. A slightly depressed condition of the anterior fontanelle is one of the earliest symptoms showing the amount of water in the system to be below the standard. Fretfulness, moderate rise of pulse and temperature, a hot, dry skin, and frequent desire to nurse, are other signs.

The Dublin Branch of the British Medical Association.

THE annual general meeting of the Branch will be held on Thursday, 31st January, at four o'clock p.m., in the Hall of the King and Queen's College of Physicians. The officers and council for the ensuing year will be elected. Dr. Edward Hamilton, President-elect, will deliver the annual address. The annual dinner of the Branch will also be in the College Hall, at seven o'clock p.m., on the day of the meeting. Dinner tickets for members before Tuesday, the 29th inst., 17s. 6d.; after that date, and for guests, £1.

Traction Suture.

DR. ALLIS, writing in the *Annals of Anatomy and Surgery*, says that when a large portion of integument has been cut away—as in removal of the female breast—the healthy borders sometimes cannot be fully approximated; and even an attempt to do so is accompanied with such a degree of tension that the sutures soon cut their way out. To distribute this tension, after drying the skin thoroughly, he applies strips of adhesive plaster (from the margin of the wound in the direction he wishes the sutures to hold. He then passes his needle deeply through plaster and skin. After the sutures are in position, and before tightening them, he requests an assistant to approximate the margins of the wound by pressure from his hands, while he secures them by twisting the wire.

Sutures employed in this manner have a firm hold upon the plaster, exert their traction upon a large surface, are less irritating and harmful, and will continue an efficient action much longer than the ordinary integument sutures.

THE value of pilocarpine in the treatment of severe hiccough, to which attention was called some time ago in the *Revue Médicale Chirurgicale*, has been confirmed by the success attending its use in a very severe case which had lasted for three months and resisted all other remedies. Dr. Ruhdorfer administered a subcutaneous injection of the hydrochlorate of pilocarpine (of the strength of 3 centigrammes in a gram of water) and the hiccough was at once cured.

Carcinoma and Lupus.

BEFORE the last sitting of the Berlin Medical Society for the old year (Dec. 19th) Herr G. Lewin showed a case of carcinoma developing on a basis of lupus. He stated that eight years ago he had collected accounts of 14 or 15 similar cases from the writings of such distinguished men as Esmarch, Volkmann, Thiersch, Hebra, &c., and since that time he had collected, and observed himself, others that brought the number up to about 20. The case exhibited was that of a man 44 years of age, whose father died of *carcinoma ventriculi*. He had suffered ten years from lupus, and five years ago the present tumour began, and eighteen months ago suddenly developing to a considerable size.

Set Work versus Open Books.

THE head masters of the principal British public schools have been appealed to to decide from their own experience whether it is better to restrict the claims on candidates at public competitive examinations to particular indicated books, or to demand ability to read the classics from any work selected for the purpose by examiners. The result is that out of 94 opinions 83 agree in regarding the candidates who pass examinations in unseen passages as infinitely more admirably educated than those who are able to make skilful translations of passages specially selected and pre-announced. This decision has an importance beyond its mere seeming, for it includes the principle that cramming, which consists essentially of acquiring known subjects, is less useful as an intellectual training than *bona fide* education. It is not, moreover, in classics alone this principle deserves recognition; in every branch of learning the axiom holds good; and it cannot but be a good thing first to be authoritatively insisted on in the emphatic manner the schoolmasters have adopted. Both as an intellectual exercise and as a mental training general reading must always be of higher utility than cramming of a particular subject, and in the way of health it possesses incomparable advantages which deserve to be freely appreciated.

Execution of Criminals in "Ye Olden Times."

THE *Boston M. and S. Jour.* says that the autopsies of some of the criminals executed in the early part of this century are published in an English contemporary, showing that instantaneous death by dislocation of the vertebræ was then rarely the case. That desirable result is claimed to have occurred in every one but one of "Marwood's" many executions. But before this science had been so perfected, the careful autopsies showed some unpleasant facts. For instance, John Bellingham was executed in 1812. There was no dislocation of the vertebræ, according to the record, "nor did the trachea show any sign of compression or hurt. The right auricle of the heart moved at irregular intervals, with the application of any stimulus, during the period of nearly four hours from the time of execution, and for about an hour longer upon being touched with a scalpel. This motion was not strictly a contractile action, diminishing in any sensible degree the cavity

of the auricle, it was undulatory and weak, sometimes beginning at the right extremity of the auricle and moving to the left; at other times commencing and proceeding in the contrary direction. Not the least motion was observable in the left auricle, or in either of the ventricles." In the case of John Bruce, executed at Execution Dock at eight o'clock, and received so late as half past twelve, there were the same weak waving motions for a period of *five hours after execution*.

Sympathetic Colic from Uterine Diseases.

DR. CURTIS SMITH publishes an interesting article on this subject in a recent number of the *Philadelphia Medical Reporter*. In it he reviews the various well recognised sympathetic disturbances that may be traced to morbid conditions of the uterus and of the ovaries. The sympathetic disturbance alluded to in his paper is not to be confounded with the so-called uterine and ovarian colic, where the pain is situated and felt in these organs themselves, but that which is characterised by pain in the stomach, or more frequently a pain diffused over a large space around and above the umbilicus. It sometimes seems to be over the transverse colon, and at others it extends downwards to the upper margin of the hypogastric region. It is spasmodic in character, just as is common gastric or intestinal colic. It is accompanied with nausea and vomiting. Food vomited may or may not be sour—usually not so. No bile vomited unless the emesis be prolonged and severe. From gastric colic it differs in the food being usually free from acidity or fermentation, and the want of relief usually felt after vomiting in the case of indigestion. Movement of the bowels does not seem to increase or diminish the pain. The functions of the digestive organs may be performed perfectly, and yet the colic will come on without reference to their being so. In some few cases, dyspeptic derangement seems to aggravate or excite an attack. Amongst the positive symptoms of the complaint are, pain in the stomach or around the navel, or just above or below the navel, and its spasmodic character, and almost pathognomonic is the symptom, that the pain, wherever felt, is intensified by pressure over the uterus or ovaries, and if it has subsided, it may be again excited by such pressure. In one case he noted that pressing over the uterus excited severe pain under the left breast, and over an extensive area around the umbilicus. There was little or no pain felt at the seat of pressure. In another case, where there was no more than an uneasy or grumbling pain felt in the stomach, and where there had recently been some uterine disturbance, pressure over the uterus caused severe pain in the umbilical region. The writer has not been able to notice any immediate connection between the time of menstruation and the recurrence of the attacks. In most cases it has preceded menstruation about ten days. Once it occurred during the catamenial flow. It is common to married and virginal women alike. The attacks are preceded and followed by a couple of days' sense of malaise. Patients affected are languid, listless, and suffer from changes in temper, and are hysterical at times. Just before the outbreak the expression of face is dull, and there is a little dusky skin. The

pain is *real*, not imaginary. There is no fever, and the pulse and digestion are normal, or almost so. Some hours after the pain has been relieved a slight and transient irritative fever is noticeable. The subject is one of considerable interest, and further contributions are promised by Dr. Curtis upon it.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 22·2 per 1,000 of their aggregate population. The death-rates in the several towns were:—Norwich 12, Portsmouth, Bradford 17; Bristol, Nottingham, Oldham, Newcastle-on-Tyne, Hull 19; Leicester, Bolton 20; Edinburgh, Huddersfield, Plymouth, London, Birmingham 21; Derby, Wolverhampton, Sunderland, Halifax 22; Brighton, Sheffield, Liverpool 23; Birkenhead 24; Blackburn 25; Leeds 26; Salford 27; Dublin 28; Manchester, Glasgow, Preston 29; Cardiff 31.

THE highest annual death-rates in the large towns last week from diseases of the zymotic class were—From measles, 4·8 in Derby, 2·3 in Birkenhead, and 2·0 in Manchester; from scarlet fever, 4·8 in Leeds, 1·6 in Salford, and 1·4 in Sheffield and Newcastle-upon-Tyne; from whooping-cough, 1·8 in Huddersfield, and 1·4 in Sheffield and in Bolton; and from "fever," 2·8 in Blackburn, 1·4 in Halifax, and 1·1 in Cardiff. The 38 deaths from diphtheria included 16 in London, 7 in Glasgow, 2 in Birmingham, and 4 in Cardiff. Small-pox caused 6 deaths in London, 8 in Birmingham, 7 in Sunderland, 6 in Liverpool, and 1 in Manchester.

WE understand that the Council of the Irish College of Surgeons has decided that it is desirable to admit the Apothecaries' Company to the scheme of conjunction of the Irish licensing bodies for the granting of a double diploma. This determination introduces a very serious complication into the negotiations, for it does not seem likely that the College of Physicians will relish the recognition of the Apothecaries' Company as co-equal partners with them in medical licensing, and, moreover, the distribution of the diploma fee will have to be reconsidered and readjusted before the scheme can go further. We would seriously ask the Irish Colleges whether, at the present day, it is worth their while spending time in discussing a scheme beset by so many pitfalls, when it seems probable that before the negotiations can come to anything the Medical Reform Bill will have provided a summary settlement of all disputes?

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

SCOTCH VITAL STATISTICS.—From the official weekly returns of the Registrar-General for Scotland for the week ending Saturday, January 5th, the death-rate in the eight principal towns during the week was 25·4 per 1,000 of estimated population. This rate is 3·7 below that for the corresponding week of last year, but 3·8 above that for the fifty-second week of 1883. The lowest mortality was recorded in Perth—viz., 15·1 per 1,000; and the highest in Paisley—viz., 35·7

per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 8.1 per 1,000, or 0.5 below that for the preceding week. Acute diseases of the chest caused 145 deaths, or 37 more than the number recorded for the previous week.

AYR.—DEATH OF A CENTENARIAN.—There died at the farm of High Kylestone, about four miles from Ayr, Margaret Paton, relict of George Muir, in her hundredth year. Deceased would have completed her centenary if she had lived till November next. Till within twelve hours of her death she was in the enjoyment of good health, and possessed all her faculties in a wonderful degree. She was a native of the neighbourhood of Mauchline, where she was well acquainted with Gilbert Burns, brother of the poet.

ROYAL SOCIETY OF EDINBURGH.—A meeting of this Society was held in the Royal Institution on the evening of the 8th inst., Mr. Stephenson, C.E., one of the Vice-Presidents, in the chair. The chairman expressed regret that, owing to the illness of Lord Moncreiff, they would not have the privilege of hearing his lordship's review of the Society's history for the past century, which had been set down for that meeting, and it would consequently be postponed for a month. Professor Turner read a communication from Dr. G. Hoggan, of London, on new forms of nerve terminations in the skin of mammals illustrated by an account of the palm of the racoon, which has the peculiar habit of dipping its morsels of food before eating them. In the palm of this animal there are three different modes of termination of the nerves, and to these Dr. Hoggan had, with characteristic gallantry, attached the names of three ladies—Brown, Hoggan, and Blackwell. In the first, the axial cylinder divided itself into three or four fibres, which had a knob-like termination; in the Hoggan bodies the cylinder entered a structure consisting of a series of layers; and in the Blackwell body there were a number of nerve cells which had reference to each other. A paper by Professor Herdman, Liverpool, was communicated by Mr. Murray, of the *Challenger* Expedition, "On Deep Sea Investigations." Dr. M'Farlane, B.Sc., Examiner in Mathematics at the Edinburgh University, read a paper on the "Arrangement of Metals in the Electro-Frictional Scale;" and a diagnosis by Professor Bayley Balfour of a new plant was laid on the table.

GLASGOW DEATH-RATE.—For the week ending with Saturday, the 5th inst., the death-rate of Glasgow was 29 per 1,000 per annum, as compared with 24 in the preceding week, and 31 in the corresponding week of last year.

EDINBURGH ROYAL INFIRMARY.—The annual general meeting of the contributors to the Royal Infirmary of Edinburgh was held in the Council Chambers, Edinburgh, on the 7th inst., the Lord Provost presiding. Mr. James S. Trainer, treasurer and clerk to the Corporation, read the annual report by the managers, from which it appears *inter alia* that a total of 6,829 were admitted from Oct. 1st, 1882, to Oct. 1st, 1883; of these there were dismissed cured, 3,279; dismissed relieved, 1,954; dismissed on other grounds, 582; died in the hospital, 501; patients remaining at 1st October, 1883, 513. Of the cases brought to a termination during the year, 467 were cases of infectious disease treated in the Fever House in the old Infirmary, including 132 cases of scarlet fever; 2,669 were ordinary medical cases, and 3,180 were surgical cases. The number of children in the hospital during the year has averaged from 40 to 50, the great majority of whom were treated in the surgical wards. The number of deaths which took place in the new Infirmary within 48 hours after admission was 119. These were mostly cases of severe injury of a hopeless character, and they unduly raise the rate of mortality in the hospital.

During the year there have been received legacies and donations of £100 and upwards, £135,861 1s. 8d. Out of this there had to be met the following, viz.:—Sum of extraordinary payments, £2,037 1s.; excess of ordinary expenditure of Infirmary, including Fever House (£32,625 16s. 1d.) beyond ordinary receipts (£22,636 18s. 3d.), £9,988 17s. 10d.—total, £12,025 18s. 10d. Deducting this sum of £12,025 18s. 10d. from the legacies and donations received, there remains a balance for the year of £123,835 2s. 10d., of which the sum of £100,000 falls to be added to permanent capital. The ordinary income for the year—£22,636 18s. 3d., as compared with £21,713 8s. 7d. for the preceding year—shows an increase of £923 9s. 8d. This is mainly due to an increase in the receipts derived from students' fees, which exceeded by £856 12s. 6d. the sum received last year. The extraordinary income has been exceptionally large, owing to the receipt of two legacies of very considerable amount. Through the munificence of the late Dr. Duncan Vertue, H.E.I.C.S., and the late Thomas Laing, Esq., of Linhouse, each of whom has left the residue of his estate to the Infirmary, a sum of upwards of £127,000 has been added to the funds of the institution. In recognition of these munificent bequests two wards have been named the "Vertue Ward" and the "Laing Ward" respectively. The ordinary expenditure was £32,625 16s. 1d., as against £31,286 10s. 4d. for the preceding year, showing an increase of £1,339 5s. 9d.

SCIENTIFIC INQUIRY INTO THE HABITS, PROPAGATION, AND FOOD OF FLAT FISH.—Under the auspices of the Fishery Board for Scotland, Professor M'Intosh, in addition to the investigations he had undertaken on behalf of the Trawling Commission, has arranged to institute inquiries at St. Andrews, with the view of throwing some light on the habits and time of spawning of the sole, turbot, and other flat fish. The object in view is to enable the Fishery Board, by artificial cultivation or otherwise, to ensure an increased supply of an important class of fishes, at present less available than could be desired for general use, owing to the limitation of the supply obtained from Grimsby and other fishing stations, and the consequent enhancement of price. For the purpose of the inquiry, Professor M'Intosh is to be provided by the Board with tanks and other appliances, which will also be found serviceable in reference to the work to be done for the Trawling Commissioners. While the sole and other flat fish receive special attention at St. Andrews, the herring and its congeners will, it is understood, be investigated at North Berwick, where the Fishery Board propose to establish a laboratory for the purpose. In carrying out the work assigned him, Professor M'Intosh will have the co-operation of Professor M'Kendrick, Glasgow; Professor Stirling, Aberdeen; and Professor Schafer, University College, London. Meanwhile, it appears the fishery officers at the Boards, twenty-six stations on the coasts of Scotland, as well as the Board cruiser *Vigilant*, are successfully collecting materials which, it is expected, will throw light on the somewhat obscure subject of the food of fishes. The working out of this branch of inquiry is in the hands of Professor Cossar Ewart, Convener of the Fishery Boards Investigation Committee, and Mr. J. Duncan Matthews, laboratory assistant at the University of Edinburgh.

AYR.—HEALTH LECTURE.—The second of the course of Health Lectures organised in Ayr in connection with the Combe Trust was delivered by Professor George Buchanan, of Glasgow, to a large audience on the 7th inst. Mr. R. M. Pollok, of Middleton, presided, and Professor Buchanan delivered a very impressive discourse on "Surgical Accidents

and their Management," which he illustrated by diagrams and preparations.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 5th inst., the mortality in Edinburgh was 96, and the death-rate 20 per 1,000. Diseases of the chest accounted for 50 deaths, and zymotic causes for 16, of which 1 was due to fever, 1 to diphtheria, 6 to scarlatina, and 7 to measles, the intimations of these diseases for the week being 2, 8, 40, and 205 respectively.

Literature.

LECTURES ON CATARACT. (a)

It is not quite so easy to see why a lecturer of repute should, "at the urgent request of his old pupils," consent to the publication of lectures for which he believes "he can claim neither merit nor originality." To what must we attribute this diffidence on the part of the author? He cannot wish his readers to believe that there is literally nothing new to be said or written about cataract? On reading over Mr. Cowell's pages, we are inclined to the opinion that his book is not so devoid of merit as he would have us suppose. No doubt "old pupils," and new also, "who feel an interest in ophthalmic subjects" will read over these lectures, which were "delivered without any idea of publication," with pleasure if not with profit.

An anatomical description of the crystalline lens is given as a prelude to the correct diagnosis of the various forms and modifications of cataract, and the operative measures for its relief finish up the course. At the outset we question the soundness of some of the author's views. In the first place, in diagnosing cataract, we doubt whether "the straining of accommodation by continuous work at minute objects" is a very common cause of cataract, or whether synechia anterior, "a false membrane occupying the pupil," is at all likely to be mistaken for "a false or spurious cataract." The condition of the patient's vision, as well as that of the iris, will prevent his "old pupils" from falling into so gross an error of diagnosis. The hereditariness of cataract is well understood and acknowledged; and with reference to the visible stellation of the cataractous lens, there is nothing either new nor remarkable in the fact that these rays are fissures formed by the discontinuity of the lens fibres, where the endosmotic processes are most active, and showing most probably the lens itself affected by deranged nutritive changes. The evidence adduced is quite insufficient, in our opinion, to establish "a curious fact," mentioned by Arlt, that "lamellar cataract often occurs in children who have been the subject of convulsions." Neither can we concur in the author's opinion that a connection can be shown to exist between "the capsular form of cataract and the purulent conjunctivitis of infancy."

Although Mr. Cowell holds fast to the commonly received opinion that cataract "usually depends upon some alteration, perversion, or impairment of nutrition in the lens, rather than upon pathological change around and outside the lens," he does not believe cataractous disease can be amenable to medical treatment. A prophylactic is, indeed, useless, "as cataract can only be successfully treated by operation." So far his views are in accord with those of another specialist who gave the introductory at one of the medical schools a few weeks since, and who is even more emphatic on this point. His words should be noted and digested. "The medical profession would retain the most important part of its duties and all, or more than all, its present share of honours if every drug in the pharmacopoeia were to become extinct." With a larger experience of the value of drugs, we venture to think that these extreme views will in time undergo very considerable modification. Will it be denied that in diabetic cataract medical treatment is of no value? Can it be said that belladonna or atropine is useless in iritis? or eserine in cases of increased hardness of the globe—that is, in a diseased condition frequently mistaken for glaucoma? In rheumatic affections of the eye, is the administration of iodide or bromide of potassium of no avail? Such statements can serve no good purpose, they are altogether misleading. Passing to the operative treatment of

cataract, Mr. Cowell's refinements remind us of Warlomont's jocular remarks on the practice pursued at the London ophthalmic hospitals. "I asked," he said, "in all what method of operating was employed, and I received for answer: We operate by the method of Von Græfe, but we modify the operation to suit the case. But it was evident enough that the old classical method is not yet abandoned." We gather from the author's pages that it is still so; every practitioner has a selecticism peculiarly his own: a spoon, a hook, or a knife constituting a sufficient difference to enable him to tabulate cases which clearly enough show the success of his method of operating. This course of "Lectures on Cataract" will, we venture to think, have fulfilled the object Mr. Cowell had in view when he consented to their publication if they are found to supply "old and new pupils" with so much of sound information as shall keep them in their after career from falling into any serious error in the diagnosis and treatment of cataractous disease.

TRANSACTIONS OF THE ACADEMY OF MEDICINE IN IRELAND. (a) VOLUME I.

THE various medical societies in Dublin having merged their individuality, they now constitute the Academy of Medicine in Ireland. Our professional brethren in the sister country are to be congratulated on having taken this step for the advancement of Medicine and Surgery. Dr. John T. Banks had the honour of being elected the first President of the new Academy; and Mr. William Thomson holds the office of General Secretary. To the latter, as Editor, we are indebted for the production of the first volume of Transactions, representing the labours of the several Sections of the Academy—in Medicine, Surgery, Obstetrics, Pathology; and the Sub-sections of Anatomy and Physiology, and of Public Health.

We cannot undertake (no one writer could presume) to enter upon a critical dissertation respecting the merits of the papers contributed in all these departments of investigation, which are co-extensive with the whole range of Medicine properly so called; nor would it be quite an easy task to make a selection for this purpose from any one Section in the Transactions. But we may notice certain papers which relate to subjects of more recent progress.

In Surgery, Mr. O'Reilly contributes "A Case of Nephrectomy by Right Lumbar Section," the interesting features of which consist in the operation having been performed for the removal of a kidney affected with miliary tubercle, and which had resulted in pyonephrosis. The operation, under the influence of ether, was conducted antiseptically; and by an oblique lumbar incision, from the eleventh rib to the iliac crest, just in front of the erector spinae. No hæmorrhage occurred, nor subsequently. But the patient died in forty hours from persistent vomiting. Among the conditions which rendered extirpation of the kidney justifiable, very judicious stress is laid upon the absence of pain or tenderness in the region of the other kidney, and the normal character and quantity of the urine secreted, as further indicating the healthy state of the companion organ. Other equally important papers relate to "Trephining of the Skull for Cerebral Abscess," by Mr. Kilgariff; and "Trephining in Mastoid and Tympanic Disease," by Mr. W. I. Wheeler. Mr. Thornley Stoker communicates a most valuable and exhaustive paper on "Removal of the Thyroid Gland," accompanied by an excellent lithograph of a case. Dr. Kendal Franks gives two remarkable examples of "Spontaneous Dislocation of the Hip," of which there are other instances on record by Stanley and Verneuil, and to which reference is made.

In the Medical Section we may notice "A Case of Empyema treated by the Radical Method, with Notes of some Antiseptic Fluids employed," by Dr. R. A. Hayes. Empyema calls for surgical interference more urgently than hydrothorax; for, in addition to the pressure under which the lung labours, there is the risk of septic infection. Dr. Hayes' case was one of empyema on the right side, and opening into a bronchus. It is a significant fact that the antiseptic spray was discarded, and that oakum was used as the antiseptic dressing, good drainage also being provided; and these precautions proved successful after aspiration and carbolic injection had failed. We must add, however, that the patient's recovery was

(a) "Lectures on Cataract." By George Cowell, F.R.C.S., &c. London: Macmillan & Co. 1883.

(a) Transactions of the Academy of Medicine in Ireland. Vol. I. 1883. Dublin: Fannin & Co. London: Baillière, Tindall & Cox.

retarded by an attack of erysipelas, and by the formation of superficial abscesses over the scapulae, besides other complications, which could hardly have had any relation to septic infection. In the course of treatment four antiseptic washes were tried—carbolic acid, eucalyptus oil, salicylic acid, and boracic acid; but each such agent was used in a very weak solution, not more than 2 per cent., and the carbolic wash being less than $\frac{1}{2}$ per cent. As bearing upon the therapeutic value of "Nerve-Stretching," Mr. W. Stokes reports two cases of *tubercles dorsalis* in which this procedure was tried, by traction of one or both sciatic nerves; and with temporary relief of the lightning pains and some restoration of motor power. The particulars relating to the operation in these cases clearly show that the author fully appreciates the conditions which are essential to success, with regard to the force of traction necessary, gradual extension, and the stretching of the nerve in both directions. Dr. W. Frazer draws attention to a class of cases in persons known as "Bleeders," but where "sudden death resulted from cerebral hæmorrhage;" and Dr. W. G. Smith narrates a case in which a "laryngeal polypus" was removed by Voltolini's method—a kind of evulsive procedure, which can be applicable only when the growths are polypoid. It is a brushing mode of extraction, analogous to the method of M'Ruer for the clearance of nasal polypi.

Among the papers in the Obstetrical Section, that by Dr. T. M. Madden, on "Mental and Nervous Disorders peculiar to Women," is most suggestive, and full of interest. It will well repay perusal. An original communication by Dr. Lombe Atthill throws light on the nature of "Metria" or "So-called Puerperal Fever," and on the relation of this puerperal uterine condition to septicæmia.

The Pathological Section abounds with papers of great moment. The first, from the pen of Mr. J. K. Barton, records a case of "Intestinal Obstruction," from torsion or volvulus of the cæcum! For the relief of tympanitic distension of the abdomen, puncture of the bowel was resorted to, giving vent to a large volume of extremely fetid gas. Antiseptic precautions were taken. Abdominal section was not performed. The patient died five days after admission to the Adelaide Hospital, having previously suffered for three days from abdominal symptoms. On post-mortem examination the cæcum was found to be twisted twice upon its axis, causing complete obstruction at the junction of the colon. Dr. T. E. Little exhibited a specimen of "Aneurism of the Internal Iliac Artery," which illustrates several facts of practical importance. The aneurism was a fusiform dilatation of the left artery, and continued into the obliterated umbilical artery—not in the direction of the iliac branches. The sac had undergone consolidation by laminated fibrine, leaving a narrow channel. This rare mode of spontaneous cure—of which Hodgson mentions several instances, is most complete, by restoring the arterial wall, and yet maintaining also the continuity of the vessel. If the same result could be obtained by surgical art, it would revolutionise the treatment of aneurism. In Dr. Little's case, the aneurismal enlargement was unaccompanied by any such affection of any other artery—another exceptional fact; although, as usual, the arterial system bore evidence of extensive degenerative changes. "The Influence of Fractures on the Growth of Bone" opens up a wide field of inquiry, and of considerable difficulty—as with reference to the question whether an increased thickness of bone may depend on callus formation only, or additional hypertrophy? The growth of bone in length can be more exactly determined, even when the fracture has resulted in longitudinal displacement. These and other factors in a complex physiological problem are ably considered by Mr. James Davison, and if the observations he has adduced are not entirely conclusive, they at least prepare the way for further investigation.

The Sub-section of Public Health has begun to do good work in this direction, and especially touching the predisposition engendered by "Consanguineous Marriages," as in relation to "deaf-mutism"—a great social question into which Dr. C. A. Cameron has entered to some extent.

Having thus reviewed the first volume of the Transactions which has emanated under the auspices of the Academy of Medicine in Ireland, the profession will look with confidence to a continuation of its labours, animated by the true spirit of inquiry, and with results which bear the stamp of merit; so that we shall anticipate annually to gather some such mature fruit from off the same tree.

F. J. GANT.

Correspondence.

SIR JOSEPH LISTER AND THE TREATMENT OF FRACTURE OF THE PATELLA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have to-day, for the first time, become aware that your issue of the 26th ult. contains an editorial statement to the effect that a patient operated on by me for fracture of the patella since the delivery of my address to the Medical Society has died. Your informant, whoever he may be, is mistaken. I have operated on three cases of fracture of the patella during the period referred to; and of these, two are healed and the other promises to be so before long.

Yours, &c.,

London, 8th January, 1884.

JOSEPH LISTER.

NASAL TONE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am not aware that any explanation of the nasal quality of vocal tone has been given, beyond the simple statements that it is caused either by the passage, or by the inability to effect a passage, through the nostrils. That the former view is, so far, the correct one, I have no doubt, but that it explains the cause, I fail to see. Such an explanation explains it no more than a statement that the vocal tone passes along the pharynx after leaving the larynx. The sole cause I believe to be the division of the tone by the nasal septum.

Yours, &c.,

C. R. ILLINGWORTH, M.D. Edin.

Clayton-le-Moors, Jan. 5th, 1884.

THE LARYNX: THE ACTION OF THE FALSE VOCAL CORDS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I notice that the controversy in your columns on Voice Production has come to a conclusion in which nothing is concluded. Having had no part in that controversy, nor desiring to reopen it, will you permit me, as an outsider deeply interested, to say a few words on the approximation of the false vocal cords, chiefly led by your remark that "the laryngoscope so far has thrown very little light thereon." As a statement of fact no doubt this is correct, and it suggests to me very forcibly the desirability of asking laryngoscopists to direct their attention to its reversal, by such a course of investigation as shall leave no doubt of thoroughness. Disregarding, for a time, the vocal ligaments, let the aim be to ascertain the actual states of the false vocal cords during different breathing efforts, and during the emission of sounds musical or non-musical, anything, in fact, tending to determine for us what the differences in condition, what the variations in activity coincident with changes in position of other adjacent parts of the vocal apparatus. The difficulties attending such an inquiry, undoubted as they are, will be surmounted, and patience be rewarded by some truth worth having. I do not intend by my suggestion to assume that the ventricles beneath the false vocal cords are inflated during phonation, for my studies lead me to infer that the physical action is exactly the contrary of inflation; neither would I imply that the false vocal cords are approximated in the same way and to the same degree as are the true vocal ligaments when vibrating, but that the false vocal cords do change their position in varying degrees is not, I believe, disputed, and the points to be decided are, how much do they approximate, from what causes, and for what end? Merkel very plainly shows that changes do take place, that there is a position accompanying a low pitched note, and a distinctly new position when the voice is singing in the higher range of pitch. For scientific value the investigation should be directed to ascertain specifically what the changes of this nature are when different notes are sung, and when the quality of tone is varied, also whether the changes are manifest in similar degree when tones of like pitch are produced by different individuals, so that by comparison of

a number of instances an accurate chart might be mapped out, to serve as a guide for the scientific thinker. However minute the differences observed, each variation will have a meaning. Whether with the laryngoscope good vocal tone can be produced is beside this particular question. My object is to take the matter away from the argumentative influence of teachers of singing, and to ask for facts as observed by competent users of the laryngoscope; and, in this I think, the medical profession may help, as only those can who are familiar with disease, and who have before them in their practice abnormal cases, and instances of accidental injuries, affording opportunities for insight into Nature's working, which lost may never recur. The knowledge that such observation is wanted in aid of scientific research may perhaps induce some surgeons to take notes, and afford information concerning this at present obscure detail of the vocal apparatus.

Yours, &c.,

INVESTIGATOR.

[We have excised a paragraph in our correspondent's letter which would have re-opened the old controversy.—Ed.]

THE PROGNOSIS OF SYPHILIS—DR. CHARLES BELL TAYLOR'S STATISTICS OF SYPHILIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A few weeks ago I received from the distinguished ophthalmic surgeon of Nottingham, Dr. C. B. Taylor, a pamphlet on the Contagious Diseases Acts, which contains so many facts new to me with regard to the spread of syphilis in this country, that I should like to notice them.

It seems that when the North Yorkshire Militia were examined carefully some six years ago, at Scarborough, with a view to test whether they were greatly affected with venereal diseases, there were only three cases of sores found among 600 men; when again examined in 1880 there were only two cases of sores in 600 men; and in 1881, only three cases in 650 men. And, when the Queen's Militia of Staffordshire were carefully examined with the same view in 1877, there were only two such cases of sores among 928 men besides officers; in 1878, only two cases among 799 men; in 1879, only one case among 1,003; and in 1880, only two cases of sores in 1,051 men.

In addition to this we are told by Dr. Taylor that, when 5,830 militiamen from all parts of the country were examined at Aldershot, only one case of true syphilis was found among them.

With regard to the prevalence of hereditary syphilis, it seems that in the case of 10,000 factory children, who were examined singly and separately for the purpose of seeing whether they showed any sign of the disease, not one showed any clear mark of it, whilst the reports of the hospitals for sick children in Great Britain and Ireland show that infantile syphilis is only found in about 1·4 per cent. of all the cases seen.

In a return made to the House of Commons in 1877, No. 260, it is mentioned that in English workhouses in twenty counties there were but 41 cases of venereal disease, and in 29 counties there had been only seven deaths from the disease. "The deaths from syphilis at all ages among paupers, including infants, children, and adults, were only eight per million, which was not quite one in 100,000, and among the general population not more than one in 120,000."

With regard to the benignity of modern cases of syphilis, Dr. Taylor quotes Fournier that "in ninety-five per cent. of all cases of true syphilis met with, the disease is truly benign." And Lancereaux who says, "It should be known that this disease becomes dissipated in a great number of cases after the cessation of the cutaneous eruption, and sometimes even with the primary lesion." Mr. Jonathan Hutchinson, too, in his Norwegian Notes remarks that "Syphilis has declined in England at least as decidedly as in Norway. Worm-eaten skulls are relics of the past, which antiquarian pathologists will do well to take great care of, for they cannot be replaced, and their value will increase. So also of the sunken nose, the destroyed palate, and serpiginous ulceration, they are now rarely seen. Nodes on the skull or tibia are in the present day interesting cases, and by no means frequent. The youngest student knows

how to cure nocturnal pains, and is only too glad to get a good case to try his skill on."

All this is very interesting, and shows that we are gradually, by constant discussion, attaining to some more positive views as to the spread and severity of a disease, which, with all these abatements, is still one of the great evils of our race.

With regard to prognosis in the case of syphilitic parents, Dr. Taylor makes some interesting quotations; and, first of all, Mr. James Lane speaks in these words, "Does not everyone whose experience is long enough know of patients who have had syphilis in their youth, have recovered in due course from all its symptoms, and who afterwards married and had perfectly healthy children?" Dr. A. Owre, of Christiania, too, who did me the favour of calling on me many years ago, to converse about the treatment of syphilis, is cited by Dr. Taylor as having watched 29 syphilitic men for several years, all of whom had married. There was, it seems, no child of any of these men affected by syphilis. Fournier, too, has pursued a similar investigation, and has recorded the histories of 87 syphilitic men whom he had watched for years, until they had become the fathers of 156 children, not one of which children, it seems, had any form of syphilitic symptom.

It is such evidence as this that has made some authors, for instance, Callier (file), say that syphilitic fathers do not communicate syphilis to their children, unless they first of all infect their wives; but this opinion seems not to be quite true, although apparently it is pretty nearly so.

Dr. Fournier, however, in his work on marriage and syphilis, is most particular in enjoining on his male patients, as well as his female ones, to postpone their marriage day and parentage for several years; and advise them in the interval to carry on a germicidal course of small doses of mercury and iodine. This seems also to be the idea of some of those physicians in the United States, who continue such mercurial courses for four years or more.

The quotations and statistics, I have cited from Dr. Taylor cannot, I think, fail to promote a more thorough discussion of that most difficult question, the prognosis of syphilis, both in this country and abroad.

Yours, &c.,

C. R. DRYSDALE, M.D.

London, January 9th, 1884.

THE CONJOINT EXAMINATION SCHEME.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have to thank you for inserting my letter of the 2nd inst., directly opposed as it was to your own views, and you will in the same spirit of impartiality, I have no doubt, allow me to still further discuss the question, especially as we are animated by the same desire to do that which is best for the public welfare, the profession, and the Colleges concerned. I recognise the same spirit in the publication of a letter on the Medical Reform Act, signed "F.R.C.S.I., Ex-President of the Irish Medical Association." Who the writer of that admirable letter is I know not. I very much regret he did not put his name to it, but I endorse every word he says, and sincerely trust his letter may have the effect he desires of awaking the attention of the profession to the importance of the subject he discusses. At present, however, it is the conjoint examination scheme that is before us.

In your comments on my letter you deny that there exists between the Irish Colleges any system by which half-qualified or half-educated men are put forward as State guaranteed practitioners, and you characterise such a statement as a libel on the holder of the R.C.S.I. and the L.K.Q.C.P. I think I expressed my views on this subject sufficiently clearly to render it unnecessary to defend myself from the charge of libelling the holders of the licence of our Colleges. The fact, however, remains that, notwithstanding the excellence and completeness of the education implied in the licence of the Irish College, the holders of either of those licences are, in the eye of the law, but half-qualified, and cannot hold a public appointment in these countries without obtaining further licences in medicine, or surgery, and midwifery. To be eligible for public appointments in this country candidates must, under present circumstances,

either undergo three separate and distinct examinations, going over nearly the same class of subjects, and pay three sets of fees; or else go to Scotland, where the several corporations have arranged to give the necessary licences on one examination and on the payment of one set of fees. The object of the proposed conjoint scheme is to enable the Irish corporations to qualify their licentiates to hold those public appointments without forcing them to adopt either of the foregoing expedients, and to thus retain Irish students at home, and induce them to connect themselves with home institutions, whose reputation and fostering care would best serve them in their future career, while the institutions themselves would derive influence and support from the connection so established. That this will involve some sacrifice on the part of the Colleges is quite true. Some pecuniary sacrifice, it may be—some sentimental, also; but surely the benefits to be obtained will more than compensate for either or both.

You estimate the pecuniary loss to the College of Surgeons at from £1,000 to £1,100 per annum. This you place under two heads—first, the loss of £459 5s. a year because of the reduction in the price of the diploma; and, second, a further loss of £605 10s. because, as you assume, thirty-five licentiates whom you believe are content with the single licence of the College of Surgeons would, if forced to take the double licence, be “alienated” and go elsewhere. This assumption is, however, utterly groundless. Is it to be believed that these thirty-five men would be satisfied with this half-qualification, under which they could not hold any public appointment in any part of Her Majesty's dominions if, on the same examination, and at an additional cost of merely five guineas, they could get a complete qualification, making them eligible for any public appointment? I cannot believe any thirty-five sane men could be guilty of such folly. May we not with more reason point to the fact that thirty-five men register on this half-qualification as affording overwhelming evidence of the necessity for the adoption of the proposed scheme, and assume that they would gladly, if it were placed within their power to do so, avail themselves of the opportunity to acquire the qualification regarded as complete by the law of the land?

There is, however, another element in the calculation of which you altogether lose sight. Of the many men who at present are drawn to Scotland to get a complete qualification on a single examination and for a single fee, would not many prefer staying at home, taking their licences where they are known, and from Colleges whose reputation stands so high with the people among whom they are to practise, as ours are known to do? Is it not, I say, fair and reasonable to expect that a large proportion of these men would take the conjoint qualification of our Colleges? And if only twenty-seven were so to do, then the loss to our College from the reduction in the price of the diploma, instead of being £459 5s., as estimated by you, would be actually nil.

I am, Sir, yours, &c.,

GEORGE H. KIDD,

Past President of the Royal College of Surgeons, and
ex-President of the Irish Medical Association.

12th January, 1884.

[The arguments which Dr. Kidd advances in favour of providing the Irish student with a double qualification by means of a single series of examinations and a single diploma fee are the same arguments which we ourselves used in advocating the same proposition. But they afford no plea whatever for driving the student into that examination if it suits him better to take separate qualifications; nor do they touch the collegiate aspect of the question at all.

We repeat our entire approval of the project to form an Irish conjoint examination, but we insist that it should be entirely voluntary, and that the terms of the co-partnership between the Colleges should be equitable.

In estimating the immediate loss to the College of Surgeons at about £1,100 a year, we adopted a minimum valuation, and, as we have already said, we see no reason to hope that that

loss would be balanced by the accession of a single additional licentiate. We know, in fact, that the Irish student does not go to Scotland to seek a double diploma, and therefore that he would not be enticed to remain at home if one were provided for him in Dublin. He goes to Scotland to seek a licensing body who will take him on a two-year curriculum, three years under the old system and four years under the new system being the least times within which he can qualify in the Irish Colleges. As long as this difference of the indispensable period of study remains, so long will the Irish student go to Scotland. He does not want to save a few pounds in the diploma fee, or to get rid of a redundancy of examinations, but to save a year's residence at the Dublin schools, and a year's delay in entering practice.

We look to the Medical Reform Bill to equalise the Scotch and Irish curricula and standard of examination, and until it is equalised the Irish exodus will continue, conjoint diploma notwithstanding.

In briefly estimating the loss to the Irish College of Surgeons from this scheme we spoke only of the loss arising from the alienation of the thirty-five students annually who take the L.R.C.S. separately. Had space then permitted we would have pointed out that there are two classes of candidates who now take the licence of the College of Surgeons, but who could not accept it when combined with the licence of the College of Physicians, *even if they were given it for nothing and without examination*. These classes are: *a*. Those who intend to keep open apothecaries' shops throughout Ireland; *b*. Those who propose to go into general practice in England or elsewhere. These candidates, if they accepted the Irish conjoint diploma, would be expressly forbidden by the bye-laws of the College of Physicians to engage directly or indirectly in the sale of medicines, and would be required to make declaration that they would surrender their diploma if they violated this regulation. As a fact, a Licentiate of the College was recently struck off its list and deprived of his diploma for having sold medicines, and, as a further fact, Irish students entering general practice in England might be required to surrender their diplomas the moment it was discovered that they made a profit by supplying medicine to their patients. These two important sections of the *clientèle* of the Irish College of Surgeons would, therefore, be absolutely prohibited from taking the double diploma. And what alternative is offered them? They are invited to pursue their studies separately for the L.R.C.S.I. and for the diploma of a medical licensing body (approved not by themselves, but by the College of Physicians), to pass the two series of examinations, and to pay the double series of fees, but if they failed to pass for the medical qualification, or were prevented doing so by sickness, want of money, or any other unforeseen cause, they would get absolutely nothing from the College of Surgeons for their four years' work, it being part of the scheme that the diploma of the College should not be issued except upon production of the medical licence. Does anyone suppose that the candidate would submit to these terms? or would adhere to the College of Surgeons under such hindrances? We certainly believe that they would please themselves and avoid all risks by entering their names at the Royal Irish University, which stands with its portals invitingly open for all comers, and that in a few years the College of Surgeons would enjoy the patronage of those students and those alone who preferred the L.K.Q.C.P.I. to any other physician's qualification, and that the loss to the College of Surgeons would then more than double our minimum estimate of £1,100 a year.—ED.]

THE CONJOINT EXAMINATION SCHEMES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your editorial remarks on Dr. Kidd's letter in your last issue you point out that, as the Irish College of Surgeons examine in all the branches of the curriculum, there is no imperative need for its union with the College of Physicians. No one will, I think, give me credit for an overwhelming admiration for any of the corporations, but it is only fair to state that the College of Surgeons of Edinburgh has always examined in all the subjects of professional knowledge. The corporations that are really guilty for not doing so are the London College of Surgeons and the Apothecaries' of London and Dublin. Only of late and under great pressure has the London College condescended to examine on medicine and in midwifery for their diploma, and even now the examination is far behind that of the Edinburgh College in completeness. There is another point in which the Edinburgh College bears favourably with the other Colleges. Every Irish student will tell you that to pass in Dublin "you must grind, for it all depends upon tips." In Edinburgh grinding is not *absolutely* necessary, although it is as well to know the views of men who for the last twenty years have annually elected themselves as examiners, and will continue to do till death stops the process. The Edinburgh College is not immaculate, but its sins are not greater than other corporations, which, perhaps, is not saying much, but still it is something, and it is only fair that in the coming struggle justice should be dealt to those venerable but now apparently unnecessary institutions.

I am, Sir, yours, &c.,

H. AUBREY HUSBAND.

Edinburgh, Jan. 12th, 1884.

POOR-LAW SUPERANNUATION (IRELAND).

We understand that the Irish Medical Association and the Poor-law Officers' Association are already alert about the re-introduction of the Superannuation Bill in the next session of Parliament. In view of the engrossing work which the House of Commons has before it, it has been thought necessary to take early steps, and the Irish Medical Association has therefore enlisted the co-operation of the Colleges of Physicians and Surgeons in a deputation to the Chief Secretary, from whom an interview has been asked.

THE Guardians of the Oldcastle Union have unanimously granted to Dr. J. Atkin his full superannuate allowance of two-thirds of his emoluments on his retirement from the medical officership of the workhouse.

On Friday last, H.R.H. the Princess Christian visited the Hospital for Women, Soho Square, London, for the purpose of distributing gifts from three Christmas trees which she had provided for the patients.

PROFESSOR TURNER ON "HANDS AND FEET."

THE weekly lecture in connection with the Edinburgh Health Society was delivered on Saturday, the 5th inst., by Professor Turner, who took for his subject "Hands and Feet." In commencing a discourse on the hands and the feet, it might (Professor Turner said) be advisable to say something of the structure of the body generally. After showing the great importance of the head and trunk as compared with the limbs, the lecturer pointed out that the limb might be divided into three fundamental parts, one part called the girdle of the

limb, which was that part of the organ by means of which it was attached to the trunk. Another part of the limb was the shaft, which gave length to the limb. The third part of the limb was that which was found at its end, and was called its free end. This terminal part of the limb was either the hand or the foot, as the case might be. The girdle and shaft of the limb might be regarded as quite subsidiary in their function to the hand and the foot, the girdle and the shaft being so arranged as to bring the hand or the foot into the best position for performing that use or function which it had to perform. In the human body the limbs were called upper and lower. The primary use of the upper limb in man was to act as an organ for grasping and holding—that was what was technically called the organ of prehension. The secondary use of the upper human limb was as an organ of progression; but it was only seldom that it was used for this purpose, as in swimming or climbing a tree. In the quadruped the fore limb was used for support and progression, and was variously modified in different animals in order that it might be adapted for enabling them to move about from place to place. The lower limbs in man were the organs of support and progression, although, secondarily, they might be used as organs of prehension, because we could grasp objects with the toes. In attempting to give a definition of the foot and hand, it was not sufficient to look merely at the human body. It was impossible for us, in the study of the structure of man, to dissociate his structure from that of those animals which approached most closely to him in bodily organisation. The hand and foot were not purely human structures, so that in giving a definition of them they must look at them from two points of view. They might look at them anatomically—from the point of view of their construction; or physiologically—from the point of view of the use or function to which they were put. Perhaps, in addressing such an audience, it might be better if he looked at the subject from the physiological rather than the anatomical standpoint. The human hand was the highest type of hand. Let them think for one moment of some of the things which had been done by the human hand when inspired by an efficient brain. It had built the pyramids of Egypt, in all their symmetry and massiveness; it had produced in metal filigree work, and in thread lace work, which rivalled in their delicacy and beauty the fineness of the gossamer; it had modelled in marble the Venus of Milo, a figure which in its form and proportions embodied the highest type of female grace and beauty; it had depicted on canvas, in the great picture Madonna, a countenance filled with the mystery of humanity. When they contemplated work so wide in its range and so varied in its character, they were naturally tempted to ask what was the construction and mechanism of the human hand, which enabled it to be applied so effectively for the discharge of work which in one direction required the exercise of great strength and freedom of movement, and in the other delicacy and lightness of touch, combined with movement so fine as to be almost imperceptible. Looking at the human hand, they might say that it consisted primarily of three parts—the wrist, the palm, and the digits, which were five in number. This was the highest number found in the human hand, or in the corresponding region in quadrupeds. To each of these digits in the human hand a special name was given. The thumb, although the shortest, was the thickest and most powerful of all the digits. It was called by the Latins *pollex*, and it had also received the name of *digitus doctus*, the skilful digit. Indeed, the power of the thumb was recognised in familiar speech. One man, for instance, was said to have another man "under his thumb"—that was to

say, he had complete power over the other man. The next digit to the thumb was the index finger, with which men pointed or beckoned. It was the most movable finger, and that was the reason it was used as an index or beckoner. The middle finger was very important on account of the length it possessed. The next was the finger they were all familiar with as the ring finger. It was the finger on which, on the left hand of a woman, the wedding ring was placed, and they might perhaps ask why it was that this particular finger had been selected for applying this very important article around. The practice was a very old one indeed, going back to classical times. This finger was selected because it was believed that a nerve passed directly from that ring finger on the left hand to the heart. (Laughter.) He need scarcely tell them that no such nerve had ever been seen. Last of all was the little finger, which was the least important of the digits. Looking at some of the properties of the hand, they found that they might be stated as follows:—It possessed flexibility, elasticity, mobility, sensibility of touch. These properties were due to the number of bones and joints it contained. Eight small bones entered into the formation of the wrist, five into the palm, and fourteen into the five digits, so that the number of bones in the limited region of the hand far exceeded the number found in the girdle and shaft—in the former there being only two bones, and in the latter, notwithstanding its great length, only three. Having explained at considerable length the anatomical structure of the hand, and the way in which its movements were controlled, Professor Turner, in conclusion, said that in man the limbs were specialised for the performance of distinct and definite duties, and in accordance with the law that the part was set aside for the performance of special duty, each limb was constructed so as to be adapted most efficiently to perform that particular work which it had to do. The lower limb could be straightened at both the hip and the knee-joints so as to be brought below the body, and the sole of the foot could then be so planted on the ground that we could stand either on one foot or both feet. The spine could be elevated so that its axis became vertical, and the body remained in an erect attitude, an attitude which was characteristic of man. The head was balanced on the summit of the spine, and could be moved to and fro so that the eyes exercised a wide range for vision. Then the head had a brain far more highly organised than was possessed by any other animal. The upper limbs, liberated from the necessity of acting as organs of support and progression, could minister to an intelligent mind, and through their strength and adaptability could enable man to fulfil the great command which was imposed upon him in the beginning to "Go forth over the earth to subdue it, and to have dominion over the fish of the sea, over the fowl of the air, and over every living thing that liveth upon the earth."

AMERICAN DIPLOMAS.

As the time approaches for consideration of the proposals to the Medical Bill with reference to the recognition and registration of foreign and colonial diplomas, it may help discussion if we refer to a recent address delivered before the American Public Health Association by Dr. Reeves, Secretary of the West Virginia State Board of Health.

The depreciated value of an American medical diploma (he said) is a reproach to the profession. This opinion is fully warranted by my own experience as a medical examiner. Not long ago a young gentleman, a graduate in medicine, when asked, "What is semeiology?" answered, "A description of the spermatozoa."

But the most shameful exhibit, involving the character of

a medical college in "good standing," that has come to my knowledge, is shown in the following correspondence:—

My dear Sir,—A friend writes me that you propose attending medical lectures. I write to present the claims of ——— College. Good boarding, costing elsewhere twenty to twenty-five dollars, can be had here for twelve to fifteen dollars per month. Railroad fare is only half rate. No school has better facilities for medical teaching than the ——— Medical College. As I am allowed a certain number of beneficiaries from your State, I will take you as one and charge you only fifty dollars instead of eighty dollars. With this reduction, cheapness of board, and reduced railroad, you can attend one of the best schools for less money than an inferior one. Let me hear from you. Send names of other students.—Yours truly,

This letter was a tablet copy—probably one of a hundred of the same kind sent out to catch the unwary. Its heading is freely illustrated with the name and picture of the college, and contains the names of the faculty, trustees, and "demonstrators." In order to sound the depth to which "Demonstrator" might be willing to descend in fishing for students, regardless of quality (?), a veritable medical student sent the following letter of inquiry, with orthography and syntax specially set for the occasion:—

One of mi Friends who is trying to be a Doct has got a letter from you which says your College is one of the Best Colleges For Medical Teaching in America and that the Fees are cheaper than some other good Colleges and that sutes my circumstance for I am a very poor young man and no matter how much I may know of Thery of Medicin I cant practice in W Va. without a Diploma from a good College like the one you have in ——— you offered to take mi friend for fifty dollars and you will do a poor young man a favor if you will take me at the same Rate I have gone through with grays anatomy and the electric dispensary and medwifery please tell me how long I will have to stay and when I can get my Diploma and if I have to pay extra for it.

In haste Yours Respectful.

A prompt reply was sent to this Wheeling student, showing that the style of his English composition was no bar to admission at ——— Medical College.

Such facts as these, and the Detroit *Lancet* says that they are but too common, make the very name of Medical College a by-word and a hissing in the minds of all honest, thinking men of all classes.

Notices to Correspondents.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

COMMUNICATIONS ACCEPTED.—The following are accepted, with thanks, and will appear as space permits:—

MR. EDWARD COTTERELL, "Notes on the Use of Apomorphia in Infantile Convulsions."

MR. HUGH OWEN THOMAS, "On Fractures of the Neck of the Femur."

DR. W. H. PEARSE, "On Consumption Viewed in Relation to Evolution and Molecular Energy."

DR. G. KINLOCH PATERSON, "Cases of Midwifery in Bygone Times."

MR. W. BERRY, "A Case of Croup in a Girl ten years of age, in which Tracheotomy was performed;" also a "Note on Hinton's Plaster-of-Paris Machine."

COMMUNICATIONS DECLINED.—Dr. J. M. M.—Likely to provoke discussion on a subject to which we have already devoted much space.

MR. W. T. S.—An every-day occurrence, without any unusual symptoms or treatment.

MR. FRANKS.—The value of arnica is disputed by some authorities, and among others by Dr. Garrod, who attributes the results produced by the tincture to the action of the spirit contained in it. He affirms that equally striking effects follow the local application of rectified spirit, as are observed when tincture of arnica is employed.

DR. ROBINSON.—It would have been impossible to obtain an examination of the body in the absence of leave given by the friends, except under an order from the coroner. The circumstances did not justify the latter being given, and hence the omission, which we agree with you in regarding as something of a misfortune.

DR. R. L.—Please accept our best thanks for your letter, the subject of which has, however, been sufficiently discussed for the present. It will probably again arise in a new connection within a short time.

THE ROGERS TESTIMONIAL FUND. (TENTH LIST.)

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The following additional subscriptions have been received since the announcement in last week's number of the *Medical Press*.

Yours, &c.,

J. WICKHAM BARNES, Hon. Sec.

Poor-law Medical Officers' Association,
3 Bolt Court, Fleet Street, London, January 14, 1884.

Dr. Henry Drinkwater .. £1 1 0	Dr. Turtle £0 10 0
Dr. Montague Thomas .. 1 1 0	E. Snell, Esq. 0 10 0
C. H. Buncombe, Esq. .. 1 1 0	Geo. Harrison, Esq. .. 0 5 0
F. Sudd, Esq. 1 1 0	C. Read, Esq. 0 5 0
Dr. Millsome 0 10 6	Dr. T. J. Hughes 0 5 0
Dr. Robert Tiffen 0 10 6	Dr. R. T. Jones 0 5 0
Dr. Lush 0 10 6	Dr. E. T. Thompson .. 0 5 0
W. Moore, Esq. 0 10 0	W. Arras, Esq. 0 5 0

MR. PEARSON.—The "Manual of Surgical Pathology," written by M. A. T. Pepper, F.R.C.S., is the best and most suitable book for your purpose. You might also consult "Ziegler's Pathological Anatomy," translated by Dr. Macalister, and published by Macmillan and Co., of Bedford Street.

DR. ARCHER.—We cannot give you a definite answer to your question until we have heard all the circumstances of the case. Unquestionably, as you state them in outline, they seem to indicate that you have not met with that courtesy one medical man might expect to receive from another.

DR. JACKSON.—The details of "Listerism" can only be carried out satisfactorily in private practice in those instances where the medical attendant is himself able and willing to devote a large amount of time and care to the carrying out of the various measures necessary to success. In all such cases, however, the result is most gratifying.

DR. PATTERSON will find his question answered on reference to the last page of this Journal for January 2.

MR. H. O. THOMAS.—We hope to commence your paper in our next issue.

DR. MACKENZIE.—A complete résumé of "The New Medical Bill" will be found in our issues for March 21 and 28, 1883. You can obtain the complete Bill of the Queen's printers, but our own résumé will probably answer your requirements.

DR. HUSBAND (Edinburgh).—Pannetier's "Leçons sur les Matières Premières Organiques" was published in 1881 by Baillière and Co., of London and Paris. It is a large volume with about 350 illustrations, and sells at 18 francs.

R. S. T.—No such consequence has yet arisen, nor is it likely to follow. The caution was uncalled for.

X. X. X.—You open up a question which had better be left for the present without discussion, although it is quite possible that ere very long it must be fully considered. So long, however, as the law is merely traditional, there will be always some to violate it, if by so doing they can consult an immediate personal advantage, even though it be at the expense of others who will seriously suffer.

MR. GRIMSHAW.—We have had no actual experience in the use of Kairin as yet, and cannot, therefore, give you any satisfactory answer to your query.

DR. WOOD.—The mistake is quite excusable under the circumstances. It involves no very serious consequences, and is hardly worth correction.

DISINFECTION.

FAIR PLAY asks: 1. Is it correct to disinfect a dwelling-house after the occurrence of a case of typhus fever or scarlatina in that house? 2. Are not the fumes of burning sulphur regarded as superior to chlorine, or indeed anything else for disinfecting purposes? 3. Does not such disinfection reduce the chance of contagion to a minimum if properly carried out? 4. I ask these queries as a very eminent physician laughed at, and if not in words, at least implied that such disinfection was a farce, and altogether unnecessary after the presence of contagious disease. He said so to a relative of the patient; therefore, either gross ignorance exists on my part in having hitherto believed in disinfection, or, if not ignorance, much unfairness on his part to make such a statement.

[The questions hardly require a reply. A medical attendant would be either grossly ignorant or criminally careless if he did not advise these means of disinfection under the circumstances, and anyone who expressed opinion to the contrary would simply make himself ridiculous. As we have not much confidence in the reports by relatives of the patient as to what the doctor said, we hardly believe that any eminent physician expressed such opinion.—ED.]

G. R. L.—ELECTRIC BATTERY.—The only battery we know of into the composition of which blotting-paper enters is the chloride of silver, of which a small-size might be bought at the price named, but its electro-motive force is very small, and, for lighting purposes, quite useless.

DR. DUNCAN.—The prescription you refer to is a simple one, and is as follows:—B Syrup Tolu, *ss*. *ss*. nit., *ss*. M. A teaspoonful when the cough is troublesome is productive of much ease, and is readily taken by patients.

ARTIFEX.—It is a common practice among maternity pupils at hospitals to express the placenta almost immediately after the birth of the child. In private practice, however, it is both desirable and politic to wait a considerably longer time; and you will be wise if you follow out your own suggestion in the matter.

SIR PRESCOTT HEWETT will please receive our thanks.

DR. HERBERT PARSONS (Monte Video).—Communication received.

Meetings of the Societies.

THURSDAY, JANUARY 17TH.

HARVIAN SOCIETY.—At 8.30 p.m., Annual Meeting: Election of Officers, President's Address and Conversations.

FRIDAY, JANUARY 18TH.

ACADEMY OF MEDICINE IN IRELAND (Medical Section).—At 8 p.m., Specimens by card: Dr. Walter Smith, Drawings—1. Multiple Onychia; 2. Peculiar Condition of Skin of Scrotum. Papers: Dr. H. V. Dillon, Bronchitis and Emphysema, loss of taste and partial loss of power of deglutition, subsequent to injury of upper cervical vertebrae (patient exhibited).—Dr. C. F. Knight, A Case of Pneumonia with Subsequent Paradoxical Temperature (patient exhibited).—Dr. J. Hawtrey Benson, A Case of Poisoning by the Ingestion of Tainted Meat.

CHARING CROSS HOSPITAL MEDICAL SOCIETY.—At 8 p.m., Mr. C. W. Heaton, On some Points in Urine Analysis.

ROYAL INSTITUTION.—At 9 p.m., Professor Tyndall, On Rainbows.

SATURDAY, JANUARY 19TH.

ROYAL INSTITUTION.—At 8 p.m., Professor Morley, On Life and Literature under Charles I.

Vacancies.

Ardee Union, Dunleer Dispensary District.—Medical Officer. Salary, £120, and £25 as Medical Officer of Health. Election, Feb. 4. (See advt.)

Ashton Private Lunatic Asylum.—Medical Superintendent. Salary, £300, with board and residence. Applications to R. H. Beaman.

Bury Dispensary Hospital, Lancashire.—Resident Medical Officer. Salary, £100, with board, &c. Also an Assistant Medical Officer. Salary, £60, with board, &c. Applications to the Secretary, Hy. Webb, Esq., Irwell Forge, Bury, Lancashire.

Coombe Lying-in Hospital, Dublin.—Assistant to the Master. Applications to the Master, 92 Harcourt Street, Dublin.

Derbyshire General Infirmary.—House Surgeon. Salary, £100, with board, &c. Applications to the Secretary by January 24.

Kidderminster Infirmary.—House Surgeon. Salary, £120, with rooms and attendance. Applications to the Secretary before January 17.

Sussex County Hospital.—Physician and Assistant Physician (Honorary). Applications to the Secretary by February 6.

West Herts Infirmary, Hemel Hempstead.—House Surgeon and Dispenser. Salary, £100, with board, &c. Applications to the Secretary by February 6.

Appointments.

BUTLER, G. E., M.R.C.S., Senior House Physician and Chloroformist to the Westminster Hospital.

DILLON, J. T., M.D., M.Ch.Q.U.I., Medical Officer to the Workhouse, Listowel Union.

GODDARD, C. E., L.R.C.P. Lond., M.R.C.S., Resident Medical Officer to the North London Hospital for Consumption.

LEE, G. T., M.R.C.S., Assistant Surgeon to Finsbury House Asylum, Salisbury.

MUMBY, L. P., M.R.C.S., Junior House Physician to the Westminster Hospital.

POLLOCK, W. R., M.R.C.S., House Surgeon to Addenbrooke's Hospital.

PULLING, H. J., M.R.C.S., House Surgeon to the Westminster Hospital.

ROUGHTON, E. W., M.B. Lond., M.R.C.S., House Physician to the Northern Hospital, Liverpool.

THURSTAN, E. P., M.D. Cantab., M.R.C.S., Medical Officer to the Tunbridge Wells Provident Dispensary.

Births.

SAUNDERSON.—January 8, at Rhode, King's County, the wife of Robert Saunderson, M.D., L.R.C.S.I., of a son.

Marriages.

FALLON-RITCHIE.—January 9 at Edinburgh, Robert Hume Fallon, M.B., C.M., of Clifton, to Annie, only surviving child of the late Walter Adolphus Ritchie, Hon. East India Company Civil Service, Bombay.

Deaths.

BEATTIE.—January 6, at Mentone, Alexander Beattie, M.D., late of H.E.I.C.S., and 45 Porchester Terrace, London.

GARRINGTON.—January 7, at Southsea, William Hawkins Garrington, M.R.C.S., L.S.A. Lond., aged 79.

JONES.—January 5, at his residence, Ladbroke Square, W., Walter Jones, M.D., formerly of Finsbury Square, aged 68.

NEVILLE.—January 11, at Maghera, co. Derry, Wm. Neville, M.B., T.C.D., L.R.C.S.I., formerly of Dungannon, co. Tyrone, aged 72.

TEMPLE.—January 2, at 38 Rotherhithe New Road, S.E., John De Liefde Temple, M.D. Lond., F.R.C.S., aged 41.

The Medical Press and Circular.

A Course of Lectures

ON

THE EYE: ITS DISEASES, AND THEIR REMEDIES.

Being an Abstract of a Course of Lectures delivered in the
Royal College of Surgeons in Ireland,

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
Professor of Ophthalmic and Aural Surgery in the College;
Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 43.)

Treatment of Granular Conjunctiva.

THE disease is to be treated—
a. By improved sanitation of the patient. b. By local astringents and escharotics.

When the disease makes its appearance in schools, barracks, or other such institutions, the first consideration is to look into the surroundings of the patients—provide for abundance of fresh air in dormitories, enjoin scrupulous cleanliness, and, so far as is possible, isolate the patients from the rest of the inmates. This is especially expedient when the disease is in the initial stage, it being then much more liable to spread than when it has become chronic. The liberal use of antiseptic lotions, combined with these precautions, and with active treatment of the cases as they present themselves, will stamp out any epidemic which may arise.

In the individual case the improvement of hygienic conditions is all-important. The patient should, if possible, sleep by himself in a room with good air space, and without curtains to the bed; the bed-coverings should be light, and he should not lie in bed after hours in the morning; while in the daytime the windows should be opened, and he should sit in a different room. Plenty of out-door exercise should be taken, walking if possible, but if the disease be in the primary acute stage, carriage exercise will do. Compress bandages, poultices, stupes, green shades, and dark glasses should all be tabooed,

cooling lotions being substituted. (a) The dietary should be looked to and reduced to the simplest and most nutritious form.

As an aid to this treatment, therapeutic help may be necessary. Children will require an antacid and alterative mercurial powder each night, (b) and—if they be weakly or strumous—a tonic mixture with iodide of iron (c) during the day. The adult will usually be the better of a brisk hepatic purgative followed by a bark tonic.

The local treatment of the disease is almost indispensable, for, once the granular condition is established, it will go on, notwithstanding the hygienic precautions, unless it is checked by suitable astringents and escharotics. In the use of these much discrimination is necessary. On the third day of the preliminary catarrhal conjunctivitis the lower lid should be everted, and search made for the "sago-grain" vesicles, and as soon as the preliminary inflammatory stage has passed away, the surface of both lids must be freely brushed over each day with an astringent solution. Saturated solution of acetate of lead is suitable if there be no corneal ulcers; but I prefer a solution of nitrate of silver, 10 or 20 grains to the ounce. If this course be persisted in, the granulations will disappear after a course of ten days, but if any chronic conjunctivitis should remain, it may be got rid of by the daily use of Pagenstecher's ointment, (d) or of the collyrium of Tannic acid and opium already referred to.

Papillary Hypertrophy.—It is, however, but rarely that, in hospital practice, the chance is afforded of treating

granular ophthalmia in its initial stage; on the contrary, the case is not usually seen until the "sago-grain" granulations have become merged in the second stage of papillary hypertrophy, this being the condition in which dimness of sight commences to trouble the patient. This hypertrophy may be developed to any extent, from the slightly rugous granular condition to great cauliflower excrescences, by which the lid is enormously thickened and swollen, so that it can scarcely be raised with the finger; the general inflammation of the conjunctiva and the symptoms which the patient experiences being of course proportionate to the roughness of the lid. This stage of hypertrophy is extremely chronic, and may exist unchanged for many months, but generally, if left alone, it will resolve itself eventually into the third, or hard, warty stage of the granulation.

In the full development of papillary hypertrophy astringents are inadequate, and escharotics become necessary; indeed, when the cauliflower granulations exist, it is best to save time by shaving them off unsparingly, and following up the treatment with escharotics or astringents. In removing them either knife or scissors may be used, but care should be taken not to cut away any part of the subjacent conjunctiva, lest cicatrices may form. The excision of the granulations should be followed for a couple of days by emollient treatment, and, when the temporary irritation has subsided, the remains of the granulations must be attacked with escharotics and astringents. The activity of this treatment must be carefully graduated according to the condition of the granular surface, but in the worst forms, the use of the solid stick of nitrate of silver run lightly and rapidly over the surface is, I think, the safest and best form of caustic. I have seen caustic potash, and also chloride of zinc, used; but these agents are so easily soluble that there is great danger of the cornea being scalded, no matter how carefully they may be washed off.

The escharotic treatment should, on no account, be pressed to the extent of producing deep sloughs, for if the conjunctiva itself be injured, the final effect will be the destruction of its function of secreting mucus—the condition known as Xerosis—and probably an inversion of the lid border. According as the granulations are reduced in volume the escharotic treatment should be mitigated—the nitrate of silver being reduced in strength by melting with it any desired proportion of nitrate of potash. In using the lunar caustic it is well to wash the lid liberally with saturated solution of common salt, for the purpose of decomposing any spicula of the caustic which might remain, and, if turned back on the corneal surface, might cause a serious ulceration. Sulphate of copper may be advantageously substituted for the stronger caustics. This latter agent I believe to be the safest and best of all astringents for this purpose; it is sufficiently active, and yet does not cause deep sloughs, and, if it does not subdue the granulations rapidly, it will certainly do no harm. A smooth-faced crystal of the salt should be rubbed on the everted lid each day, or second day, the surface being well washed after a moment's delay and before the lid is allowed to resume its position.

Hard Neoplastic Granulations.—A persistence in the foregoing treatment, and close attention to the hygiene of the patient, will always cure the hypertrophic form of granulation, without permanent injury to the conjunctiva, but if the disease be allowed to pass into the third stage, recovery cannot be obtained without more or less atrophy of the membrane and injury to its secretory function. In this third stage a new growth springs up from the substance of the conjunctiva, and presents itself in the form of a number of very hard, warty, non-vascular granules interspersed between the hypertrophied papillæ. When the hypertrophy subsides, and the conjunctiva returns to its normal condition of vascularity these new growths remain and are very refractory to cauterisation. They require the solid nitrate of silver to be applied, and it takes many weeks to subdue them.

Atrophy of the Conjunctiva and Xerosis. The chief injury which, however, they produce is the disorganisation of the conjunctiva, which becomes atrophied and loses its secretory function so that the eye no longer receives its proper lubricatory mucus. This condition of the conjunctiva is marked, on eversion of the lid, by its presenting in patches (usually close to the lid border) a smooth, shining, white cicatricial appearance, just as if the caustics had been overdone and had burned the conjunctiva. This is the condition known as *Xerosis*, and the state of chronic irritation in which the general conjunctivæ and corneal surfaces remain is called *Xerophthalmia*. In this condition, which is extremely common amongst the lower classes throughout Ireland, the lid conjunctiva is totally destroyed, and its lubricating function as a mucous membrane lost, and the eye consequently suffers from attrition with the dry and hardened lid surface. On everting the lid we find it abnormally pale and glistening with streaks or patches of a cicatricial appearance on its surface. It has, indeed, so much of the tendinous appearance of a scar that it is not to be distinguished from the result of the over-use of escharotics in the treatment of the granulations. This shrinkage of the membrane extinguishes its secretory function and bends the tarsal cartilage, so that, seen from the outside, the lid is distinctly bowed and narrowed, and if, as is usual, the lashes are not inverted, at least the hardened margin of the lid is pressed on the eyeball and creates much irritation. Entropion is a very common result, and trichiasis still more usual. In the worst cases of xerosis the ocular conjunctiva is completely dried, so that it wrinkles when the eyeball is moved, and the cornea becomes quite opaque, and the epithelial scales stick to it and accumulate in the canthi. At the same time, the conjunctiva becomes nearly dead to sensation, and the excretion of the lachrymal gland suspended, so that the normal folds of the conjunctiva are obliterated, and the surface of the eye is converted into a rough, epithelial condition.

No treatment of xerosis is of any avail, the disease being incurable. Its discomforts may be relieved to a certain extent by the constant use of emollients and lubricants—olive oil and pure glycerine are best, milk being also highly recommended by Von Græfe, the latter being especially useful because of its retaining water and keeping the conjunctiva and cornea moist.

The effusion of blood beneath the conjunctiva is a frequent result of injury, and is also commonly caused by any violent muscular effort in persons of weakly health. A fit of coughing or straining at stool is a usual cause, and it often occurs spontaneously in cases of scurvy, the patient being unaware of any lesion until he observes the appearance of the eye. This appearance is—to the ignorant—very alarming, and it is necessary for the practitioner to acquaint himself with it, lest it may be confounded with an inflammatory condition. Subconjunctival ecchymosis presents itself as a very dark scarlet patch, or patches, upon the white sclerotic, irregular in shape and in extent, and generally situated close to the corneal edge. No blood-vessels are seen on its surface or elsewhere, nor is there any inflammatory symptom whatever, but there is a uniform dark velvety redness of startling appearance. For this condition there is no satisfactory treatment. As in the case of an ecchymosis under the skin, it will persist until the blood is, by degrees, absorbed, passing meanwhile through all colours, from scarlet to purple, brown, and greenish, until it disappears. The line of treatment is to encourage absorption by stimulating the lymphatics to action, and by pressure on the conjunctiva. A lint compress dipped in a lotion containing iodide of potassium, and bandaged pretty tightly over the eye, is suitable. Tincture of arnica montana is commonly used as an adjunct, though I doubt its efficacy. Iodide of iron taken internally may be given with advantage if the patient be weakly or scrofulous.

Ecchymosis of Conjunctiva. The effusion of blood beneath the conjunctiva is a frequent result of injury, and is also commonly caused by any violent muscular effort in persons of weakly health. A fit of coughing or straining at stool is a usual cause, and it often occurs spontaneously in cases of scurvy, the patient being unaware of any lesion until he observes the appearance of the eye. This appearance is—to the ignorant—very alarming, and it is necessary for the practitioner to acquaint himself with it, lest it may be confounded with an inflammatory condition. Subconjunctival ecchymosis presents itself as a very dark scarlet patch, or patches, upon the white sclerotic, irregular in shape and in extent, and generally situated close to the corneal edge. No blood-vessels are seen on its surface or elsewhere, nor is there any inflammatory symptom whatever, but there is a uniform dark velvety redness of startling appearance. For this condition there is no satisfactory treatment. As in the case of an ecchymosis under the skin, it will persist until the blood is, by degrees, absorbed, passing meanwhile through all colours, from scarlet to purple, brown, and greenish, until it disappears. The line of treatment is to encourage absorption by stimulating the lymphatics to action, and by pressure on the conjunctiva. A lint compress dipped in a lotion containing iodide of potassium, and bandaged pretty tightly over the eye, is suitable. Tincture of arnica montana is commonly used as an adjunct, though I doubt its efficacy. Iodide of iron taken internally may be given with advantage if the patient be weakly or scrofulous.

Injuries to the Conjunctiva. The conjunctiva is very frequently the subject of more or less injury from minute foreign bodies. Particles of sand, splinters of glass, chips of stone or of iron, and the minute scales of hot slag thrown off from engine fires are the most hurtful, and they are capable of setting up much ciliary irritation, with intolerance of light and aching pain. The lesion of the conjunctiva is not of itself of much importance unless it is very extensive, but the removal of a foreign body is sometimes a difficult operation if it has remained a sufficient length of time between the lids to give rise to much intolerance of light. This is especially true of foreign bodies impacted in the cornea, but the nerve supply of the retro-tarsal fold and back portion of the conjunctiva is so limited that in that situation bodies may lie for a long time without causing much discomfort. I have seen a grain of oats retained undiscovered under the upper lid for six weeks, while, on the other hand, I have known a violent irido-cyclitis set up by a minute rust-scale impacted in the corneal edge. It is sometimes extremely difficult to discover minute foreign bodies, this being especially true of glass splinters, which, when immersed in tears, are almost invisible. To make certain that none are overlooked, it is necessary to use a powerful condensing lens, or the ophthalmoscope, to throw a pencil of rays on the eye, and having thoroughly searched the inside of the lower lid and the two canthi, the upper lid must be everted and examined.

When the foreign body has been found it is necessary to steady the eye, which is difficult, in consequence of the photophobia; indeed, in some cases of children and very nervous people I have been obliged to chloroform them for the purpose. The most convenient position for the operator is behind the patient, so that the light falls in the cornea in the best direction for observation. I generally manage without either speculum or fixation forceps, by raising the lid with the first finger, while the point of the second is pressed steadily against the side of the eyeball. The foreign body, if loosely attached, may be lifted off by the point of a blunt probe, which, if it suffices, is less liable than a sharp instrument to injure the eye on any sudden movement of the patient; but, if it be not sufficient, the point of a cataract needle, or of Walton's spud must be used. (Fig. 8.) When the body is impacted in the anterior elastic lamina of the cornea it is often so tightly held by that tough elastic structure that it has to be dug out; but it must not on any account be left to slough out, or an opacity, and perhaps a corneal abscess, will result.

Injuries of the eye from chemicals and from molten metal are of frequent occurrence, and very dangerous. The least degree of injury will be a scald of the conjunctival surface, which causes it to be chemosed and inflamed, this minor injury occurring from a splash of vinegar or of bad whisky, or some dilute chemical solution. The effect of a burn by molten metal or undiluted chemicals, such as hot lime or vitriol, is much more serious, for here the conjunctiva, and often the whole or part of the cornea, are destroyed, and a large ragged slough remains, with great risk of a subsequent symblepharon. I present an illustration of a burn of conjunctiva and cornea from a splash of molten metal. (Fig. 9.)

FRACTURES OF THE NECK OF THE FEMUR.

By HUGH OWEN THOMAS, M.R.C.S.

IN the number of this journal issued October 12th, 1882, my views and experiences regarding the principles which ought to guide surgeons in their treatment of fracture of the patella were given to your readers. Since that time the subject has been much debated before several of our societies and discussed in our periodicals. The information supplied me from this source only shows the general poverty of knowledge in relation to the treatment of fractures of the patella, for of all the gentlemen who joined in the debates or contributed to the literature of the subject, not one was able confidently to recommend a rational and trustworthy method of treatment; thus it is not surprising to find the majority of those who expressed their opinions hailing with undisguised delight the proposition that patellar fractures, whether they be simple or compound, should be treated by the knife and drill.

It would be interesting to know, if it were possible, how many of those who so readily approved of this proposal would, if suffering from the accident, submit themselves to such treatment. I have of late years maintained—and, from my experience up to this date, am more than ever convinced—that, whether the fractured patella be complicated by a wound or not, interference by knife and wiring will not give as good and safe results as can be gotten by a natural method of cure, if the surgeon knows how to aid it, or at least not to thwart it.

There are principles of treatment which, if carried out in practice, will enable the surgeon to dismiss his patient with at least a useful limb, and in the majority of cases with a faultless cure.

The evils which our past and present practice up to this time has failed to avoid are these: The patient might after treatment be enabled to extend his leg properly, or, when standing, to maintain his thigh rigidly in a line with the leg, or there might be an excess of mobility, with deficiency of power. These remains of the accident can be avoided, as I have shown in the paper mentioned above.

This contribution to the treatment of fractures at the neck of the femur has been prefaced by the foregoing remarks relative to patellar fractures because, in giving my views of the theory of treatment proper to fractures at the neck of the femur, reference must be made to principles which, I maintain, apply equally to the treatment of fractures either of the patella, neck of the femur, or of the olecranon, and here are repeated my views given in my former paper in this journal, that the treatment either of these or any other fractures, or of diseased joints, is not mainly a question of mechanics.

It is time enough to begin inventing splints when we know with some certainty what we ought to be doing to gain our purpose; then we shall be better able to decide upon the best form of mechanical aid to treatment. That some of the machines employed in treatment have advantages which aid us in the carrying out of certain principles is as obvious as the fact that other machines may be positively injurious, if these same principles ought to guide us during treatment.

Of late years there has been a surfeit of inventions the construction of which demonstrates that their inventors had no knowledge of the treatment that ought to be followed to secure a perfect recovery. Mechanical ingenuity cannot supply the place of intelligence. It is my contention that there is a rational treatment which, if adopted, leads to success in fractures of either the patella, olecranon, or neck of femur, though the mode of application must vary to suit the variation of form at the three different parts.

In the treatment of fractures of the olecranon, the mode of carrying out the principles of practice here re-

commended is very simple, as no special appliance is required to gain our purpose. The limb has merely to be maintained extended, or nearly so, by any method that does not involve in its application compression on any part within about two inches either above or below the elbow-joint, for a period long enough that firm and sound consolidation may take place. The only exception to this rule is in those cases where the fracture of the olecranon is compound and invading the elbow-joint, when the position of flexion ought to be maintained during treatment lest the injury may run a course ending in the loss of motion at the joint. Then the risk of the lesion being cured with some defect of symmetry must be incurred in order to make certain of gaining a useful result. Olecranon fractures do not cause the surgeon so much anxiety as those of either the patella or neck of femur.

Fractures of the patella happen most frequently during the prime of life, when the sufferer can ill afford to be crippled, whilst fractures of the neck of the femur most frequently occur in the decline of life; and here again it is a very pitiful thing if the sufferer must forego the enjoyment of what he had secured for himself in earlier years by being either constrained always to use crutches, or to remain in seclusion, and in most instances his repose at night is interrupted by pain, which must curtail the duration of his life.

Can any treatment, not generally known, help us to avoid these evils? Certainly,

Those of my readers who have not passed many years in the profession may perhaps think this picture representing the imperfections of our past treatment of fractures at the neck of femur as being much overcoloured, but those surgeons who have had many opportunities of observing these injuries, must know that the evils here detailed are not exceptional terminations when the hip joint has been subjected to injury, even though there be no fractures.

I am not ignorant of the fact that some cases of fracture of the patella, olecranon, and neck of femur sometimes do recover perfectly, without any treatment whatever.

Such cases only go to show that the other cases could, if we know how, be made to recover also. If none of these fractures had ever been known to recover spontaneously then we would be justified in concluding that there was in these fractures no tendency to such repair, and the experiment of direct interference would be excusable.

The unprofitable results, observed after the treatment of these three fractures, are only similar to unfortunate results after the treatment of other bony parts which are known as delayed and non-union. Our indifferent success in the treatment of the three forms of fractures here referred to partly arises from the fact that these fractures are much more prone than others to have the development of consolidation arrested, and that surgeons have not hitherto allowed for this fact, nor directed their treatment so as to physiologically favour the reformation of sufficient amount of sound connective material between the separated parts.

Our failures ought to be credited to, and can be shown to arise partly from, defective treatment.

For the guidance of the surgeon in the treatment either of fractures or of simulated fractures of the neck of the femur after injury to the joint, the following rules, which are trustworthy, may be recommended:—

If adhered to, the practitioner can in all cases promise his patient that he will so far recover as to be able to indulge in walking exercise without artificial assistance, and that he will also be free from pain.

That my readers may better understand the principles and practice here advocated, they may require an explanation of my statement, "For the guidance of the surgeon in the treatment of fractures or of simulated fractures of the neck of the femur after injury to the

joint." This refers to two forms of injury to the hip-joint, one, in which fracture of the neck of the femur exists, and can be diagnosed immediately after the injury, or some few hours after; the other injury is that following an accident, and when there is not a fracture, but after the lapse of some time—generally after the second week—many of the signs of fracture; shortening, eversion of the limb, limited motion, and the deformity of flexion, demonstrable by the flexion test.

This differs in no manner from the signs of inflamed hip-joint, which, indeed, it is, and which can be diagnosed as not a fracture of the neck of the femur by the surgeon placing simultaneously the palms of his hands upon the patient's trochanters he will notice that in fractures the trochanter of the defective limb is slightly more full, prominent, and sometimes higher up than that of the sound side.

This differential diagnosis is not of much practical value, as the details of treatment are nearly alike, whether there be fracture or not; if there be no fracture, the omission of retentive extension is not a fault, but, indeed, where fracture exists a retentive extension is not always possible of being safely applied.

When called to the patient let him at once fix the joint in a line with the trunk as immovable as possible so as to minimise the coming or present irritation of the joint, then apply any form of retention which will keep the limb at or as nearly as possible its normal length and let any bandaging that may be employed be wound in a direction the reverse of the external rotation observed in these fractures.

Let the patient be limited to a diet with the least possible ingesta lest the patient's limb be disturbed during a movement of the bowels in the period of greatest pain and when he is utterly helpless. The bowels will infallibly act spontaneously, if the diet has been properly selected (milk especially being excluded) at or before the termination of the third week, and at this time the patient will be able to assist his nurse, and movement is less injurious to him. The limitation of diet need not continue after the second spontaneous action of the bowels.

The mechanical treatment must be continued in patients beyond the age of 70 for six weeks after the total cessation of night pain, when the patient must spend a further period of four weeks in bed without any control or treatment whatever. In patients passed the age of 60, but under 70 years of age, the mechanical control should be continued for eight weeks after the total cessation of night pain, and there must be another four weeks of reclamation in bed without surgical restraint.

The younger the patient the longer must the mechanical control be continued. The duration of the periods of surgical control here laid down may appear as rather indefinite and long, but the gain here is always worth the candle.

Some cases may recover with less control, but what best conduces to make the surgeon's reputation is not a report of isolated instances of rapid recovery, but that he has always been able to benefit his patients. Fractures at the neck of the thigh-bone are extremely rare in the early period of life, but they have been noticed even at the period of childhood, and when recognised, should be treated as a mild case of inflamed hip-joint. If there has been delay in resorting to proper treatment as the surgeon is not always called to the patient's assistance immediately after the accident, the average period of each stage of treatment here laid down ought to be somewhat prolonged. Should there have been even two or three years delay the surgeon can, by following the rules here laid down, make the limb painless and useful.

The minutiae of practice which I employ can best be detailed by a sketch of a few supposititious cases which, nevertheless, are counterparts of actual ones.

Case A., æt. 70, makes a false step when coming

down the stairs of his house, and falls on his right side. Immediately feels intense pain in the groin and down the thigh; is incapable of recovering the perpendicular position, and objects to his attendants making any attempt to remove him to bed. On my arrival, an examination of the region of the hip-joint and of the lower limb convinces me that there is a fracture of the femur at its neck, there is eversion with no power of inversion, tenderness on pressure at the groin, no shortening.

I request that the patient be left where he was found after the accident, while I fetch suitable appliances—these are the posterior support and retentive extension always adopted by me in the treatment of diseased hip-joints, and of fractures at, and immediately below, the trochanter.

As soon as these are at hand, the patient is carefully undressed, the splint fitted, without the shoulder-straps, and the retentive extension is attached above the knee, and tied to the lower horns of the hip-appliance.

The knee and thigh are now bound to the upright of the saddle, the bandage being wound round in the direction of inversion, and the top ring of the saddle is fitted and tied, after which the patient is removed to bed, on a first floor if possible—though, when all this has been done, it is easy to take him up to a second floor without causing much pain. This is done by one attendant placing—in the case of the right limb being the injured one—his left hand under the upright of the saddle just below the knee, while with his right hand he grasps the left leg of the patient; a second attendant supports the sacrum, and a third grasps the top ring of the saddle opposite the sternum and carries the trunk portion of the patient, who is now placed in bed—which should be a feather one, or made of some material that does not form a very hard mattress.

After this, the person who is to nurse the patient is shown how to use the bed-pan when required, so that the patient may not be much pained nor further injured. When there is occasion for the use of the utensil, the mode of assisting the patient is thus: The attendant stands by the bedside and, passing an arm under the lower end of the hip-appliance and a corresponding part of the sound limb, raises the lower extremities and pelvis of the sufferer to any height that permits of the bed-pan being slipped under. This position, which is that of an incline from the feet to the head, if in any way advantageous, can be easily maintained until the act of nature is complete. After practically demonstrating this to the attendant, I give some instructions relative to the quality of food to be used, and that the patient must be inspected occasionally to avoid bed-sores; further, should the linen under the patient become moistened or stained by excretions, that any such offence can be removed by the method used to pass the bed-pan under the patient. The same plan can also be resorted to when dressing any bed-sores that should form.

The parts where bed-sores are prone to appear are over the sacrum and the upper ring of the saddle; if they appear at the latter part, then they can be dressed by rolling the patient over on to the sound side, by grasping well the hip-appliance and limb between the two lower rings with one hand, and the patient's shoulder with the other hand, when the operator has complete power to roll the whole body, which enables him to turn the patient over without any twisting tendency, as the lower extremity and the trunk go over in line, and thus any damage to the fracture is avoided.

In this Case A., the appliance was put on while the patient lay just where he was found after the accident, for had he been carried unprotected by surgical fixation of the part it would certainly have been more deformed and extreme shortening might have followed, though immediately afterwards there was none. A. is a typical case, but there are to be met with cases presenting

special difficulty, yet they are no bar to useful recovery, but may make recovery with no defect impossible. For instance, B., suffering from fracture of the neck of the femur. When the surgeon examines the limb he finds it closely mapped with varicose veins; in such a case it is not safe to trouble about the length of the limb, as aged people with this defect are very intolerant of the means used to form a retentive extension dressing. In such a case the shoulder brace must be substituted, otherwise the machine would slip downwards. The treatment of recent fractures of the neck of femur do not present any difficulty to those surgeons who can fit a hip-apparatus, suitable for the treatment of inflammation of this joint; but when the surgeon is called upon to treat cases of fracture that have failed to recover, and both painful and useless—cases that may have been in a non-healing condition one or more years—then the attempt by the surgeon to rectify the part requires some care for the first three weeks, the patient having really to undergo the process of the reduction of deformity, as though there had been no fracture originally treated as if it had been primarily one of simulated fracture of the neck of the femur, and the length of the limb ignored. During these three weeks the patient suffers some aggravation of pain, but it rapidly passes away as soon as the limb is in line with the trunk. To avoid much pain and not dispirit the patient, the reduction should be allowed to progress slowly, as success is certain.

The cases of simulated fracture of the neck of the femur require the same details of treatment as fractures of the femur neck, with this exception, that retentive extension is not used, but in its place I employ the shoulder-brace.

Cases of injury, simulating fractures at the hip-joint, are very frequently misinterpreted, and are rarely relieved except by mechanical treatment.

Experience has shown me that these cases are very amenable to recovery when efficient mechanical control is applied to them. The hip-saddles referred to in this contribution as used by me are made by a mechanic in my employ, but those surgeons who would wish for such appliances can get them from Mr. Critchley, 88 Upper Pitt Street, Liverpool, who supplies a cheaper and better model than any in the market.

Case C., while passing along a street, the parapet of which was rather narrow, was knocked down by a youth who careered against him, and fell on his left side. With some effort and pain he rose up, but found he could not proceed home without help. A sympathiser hailed a cab, in which he proceeded home, where he had to be assisted to undress and helped into bed, and his medical attendant was sent for.

On examination of his joint and limb, it was found that there was no shortening, despite the efforts he had made since the accident, slight eversion, pain both on pressure of the groin and on rotating the limb; also the power of eversion and rotation was diminished.

An opiate is prescribed, and the patient is directed to remain quiet—no local application. On the second day no variation of the sensational or obvious symptoms; a cloth damped in cold water is applied over the hip and groin. The patient was watched for nearly two weeks, when he began to complain of rheumatism in the joint at night; the joint was now tested by the flexion test, and a deformity noticed. Now the proper interpretation of the feeling which the patient attributed to rheumatism was given to him, and the importance of so treating the lesion that the condition resulting from the accident might not become permanent.

About the fourteenth day after the accident a posterior hip-appliance was fitted, which, for the first forty-eight hours, rather increased the symptoms and also caused some amount of lumbar pain, all of which gradually wore off. The surgical restraint was continued six weeks after the cessation of night pains—in all eight weeks, and then removed, but the patient remained five weeks

longer in bed, after which he got up, and with the aid of moderate exercise, taken by the use of crutches, was perfectly well in about eight months.

It has often occurred that uncured cases of simulated fracture of the neck of the thigh-bone have led to diversity of opinion among the surgeons whom such sufferers from "time to time" have consulted, the difference of opinion arising as to the primary nature of the lesion—the opinions of those consulted latterly seldom being in accord with the diagnosis of the surgeon immediately called to the sufferer after his accident, the latter having failed to find a fracture, there being none, but the surgeon afterwards finding some symptoms which follow fracture in connection with the hip-joint, generally suppose the delayed recovery to be due to non-union of the fractured bone. Some years ago such a case was the subject of a lawsuit, and the surgeon was successfully prosecuted for erroneous diagnosis and malpraxis. In after years the prosecutor died, and by a post-mortem examination of the joint, it was found that there had never been any fracture of the femur.

The cause of our failures to succeed in producing useful cures after fractures of the patella, olecranon, and neck of the femur have been, that even when the treatment has been correct, it has been suspended before the parts immediately and secondarily affected have regained health and its accompaniment, strength, so as to be equal to the strain of use. Another cause is the practice of compressing the seat of injury, and thus interfering with its nutrition; further, the mistaken notion founded on the pathology of the parts after treatment in past time, has dispirited surgeons from striving at better results.

THE RADICAL CURE OF HERNIA BY THE METHOD OF DISSECTION. (a)

By KENDAL FRANKS, M.D. Univ. Dub.,

Fellow Royal College of Surgeons; Fellow Academy of Medicine in Ireland; Surgeon to the Adelaide Hospital; Surgeon to the Dublin Throat and Ear Hospital, &c.

At a meeting of the Surgical Society in January, 1882, the subject of the radical cure of inguinal hernia was brought forward by Mr. Thornley Stoker. In his paper he described the successful results of two cases in which he had operated by Wood's method. The comprehensive historical sketch with which his paper opened makes it unnecessary now to travel over the same ground. The subject before us to-night embraces a larger field than was then discussed. It is no longer the radical cure of *inguinal* hernia alone, for the method which is brought before you is applicable in its scientific simplicity to all forms of abdominal rupture. The first two cases in which this method was employed were detailed by Sir Joseph Lister in his Address on Surgery at the meeting of the British Medical Association in 1871. They were adduced as illustrations of what could be done by the antiseptic method of treating wounds. Professor Annandale (b) thus describes it in 1880: "The radical treatment of hernia with the aid of catgut and Listerian antiseptics." In the strict observance of the antiseptic method lies the safety of the operation and the secret of success. The operation has been performed frequently within the last few years in America, in India, in these countries, and on the Continent, and, while operators have often differed as to minor details, they are unanimous in this, that the operation is a good one, but that it is essential that the operation be always performed antiseptically, according to Lister's method. The details of the operation itself present no novelty. It is reported of Guy de Chauliac that in 1360 he laid bare the sac, and then applied a ligature round its neck (c), while in the seventh century Paulus, an eminent Greek surgeon, describes at length the operations recommended by Celsus, which are, in fact, operations by dissection; but he recommends that, in practising excision,

a ligature should be applied to the sac before it is removed. Several of the old French surgeons used to operate as in strangulated hernia, and, after reducing the sac and its contents, they closed the openings by suture. These methods were so constantly fatal then, that Abernethy and many other surgeons strongly condemned them as formidable and dangerous; yet these are the very methods which are now advocated, and advocated because they are almost free of danger. This change is due entirely to the absolute immunity from septic disasters afforded by the antiseptic method. "We consider Mr. Lister's work as far too great to be narrowed down to a mere matter of spray and gauze," says a leading article in the *Lancet* (Sept. 3, 1881). "It is not a mode of dressing wounds that he has introduced, but a surgical revolution that he has accomplished."

The operation, which has been aptly termed in Dublin "the method by dissection," has been performed in different ways. Professor Annandale (a) enumerates four methods:

1. Ligature of the neck of the sac alone.
2. Ligature of the neck of the sac, with invagination of the ligatured sac into the abdominal opening.
3. Ligature of the neck of the sac, and excision of the neck of the sac below the ligature.
4. Ligature of the neck of the sac, with excision of the sac, and stitching together the margins of the abdominal ring.

"Having used all these methods," says Annandale, "I have no hesitation, from my experience, in giving the preference to the fourth plan."

In addition to these methods is one which I know has been practised by others in Dublin, and which I have myself practised in three cases—viz., *invagination of the sac into the internal abdominal ring, and obliteration of the canal by suturing together the rings and the sides of the canal with silver wire, which is left permanently in situ*. In this operation, no ligature is applied to the sac, nor, in many cases of recent hernia, does there seem to be any necessity of resorting to it. If the wound is kept aseptic throughout, the silver sutures become encysted, and form, with the lymph which becomes organised, a barrier past which it seems almost impossible that a hernia should descend. The operation may fail by the wound not remaining aseptic throughout, as happened in my second case, when it became necessary to remove the silver wire. If this occur, suppuration follows, which is nearly always obnoxious to the formation of firm, organised lymph. Or it may fail by the opening not being sufficiently closed—an error more likely to occur in cases of inguinal hernia than in any other, by the surgeon's anxiety not to put too much pressure on the spermatic cord traversing the canal. This error can be rectified by a second operation.

In cases, however, where it becomes necessary to ligate the sac I think that the fourth method mentioned by Annandale is undoubtedly the best—namely, to ligate the neck of the sac, excise the sac below the ligature, and then suture the openings together. In carrying out this last procedure, Annandale advises to stitch together the edges of the rings, the stump of the ligatured neck, and the surrounding cellular tissue, with a continuous *catgut* suture, and Mr. Wood himself, at King's College Hospital, employs the same method. It is better, however, to employ silver wire. This was first recommended, as far as I am aware, by Mr. Mitchell Banks, in a paper read before the annual meeting of the British Medical Association at Worcester, in August, 1882 (b), but I may say that I had employed the silver wire previously—first in April, and again in July of that year, before I was aware of Mr. Banks' views. In his paper he says: "The only point of novelty for which I take any credit to myself in this operation (and very likely others have done it as well as myself) is the use of strong silver wire to draw together the pillars of the rings, which is left permanently in position. *Catgut* I distrust; where there is any strain upon it, it yields too soon. Silver wire seems to bury itself so harmlessly that I cannot see any objection to it; while it must of necessity hold the pillars together for a considerable time, until they are well agglutinated."

The first three methods of operating enumerated by Annandale have little to be said in their peculiar favour, as they make no provision for obliterating the canal or other opening through which the hernia descends. Mr. Rushton Parker, of Liverpool, is the advocate for the third of these

methods, that is he contents himself with applying a ligature to the neck of the sac high up, but he makes no attempt to close the canal or rings. He observes that "a good many inguinal herniæ that come for operation, whether previously strangulated or not, have the pillars just as tightly braced up and as closely opposed after reduction as can be required." (a) Even in cases where the pillars are separated this is due to the pressure of the funnel-shaped sac. "If the hernial protrusion be removed the pillars of the ring may fall together. What I contend for is," he says, "that in the majority of cases, in all but extreme cases, the absence of the hernial protrusion from between the pillars of the ring is all the subsequent treatment they require." This reasoning is palpably a *petitio principii*, for no one would think of operating on relaxed abdominal rings, simply because they were relaxed, were it not that they afford no protection against the descent of a hernia, but rather encourage it. Assuming the absence of a hernial protrusion is assuming the whole question, and though in some cases ligature of the neck of the sac alone may warrant the assumption, in the majority of cases it is insufficient; as I am prepared to admit that in some cases obliteration of the canal and rings is sufficient without ligature of the neck of the sac, yet in the greater number of cases which submit themselves for operation, obliteration of the canal must be supplemented by ligature of the neck of the sac, in order to effect a lasting cure. And as suturing together the edges of the openings, whether with catgut, silk, or wire, adds nothing to the risks and little to the trouble, while it greatly enhances the value of the operation itself, there seems to be no reasonable excuse for not performing it in every case. Although Mr. Parker has been successful in many cases, still it seems hard to conceive how the cicatrix of a ligatured peritoneal sac could offer the same resistance to the abdominal pressure from within, as it could have done had it been supported by the dense tissue and silver wire in an obliterated canal.

The only two operations which seem to me to give promise of extensive application in the future are :

First, suture of the abdominal opening, without removal or ligature of the sac ;

Secondly, suture of the abdominal opening, after excision of the sac.

I have used the term "abdominal openings" instead of "inguinal canal or rings" because neither of these operations is confined to the cure of inguinal hernia alone, but is applicable to all forms of abdominal rupture, wherever situated, when within the surgeon's reach.

The first of these methods of operating is especially useful in cases of recent inguinal hernia before the sac has had time to become large and thickened, and this view is endorsed by Dr. H. O. Marcy, of Boston, (b) who published in 1871, the details of two cases of strangulated hernia, on which he had operated by this method the year before. In a paper read at the Medical Congress in London, in 1881, he says, "If the sac be small the peritoneum should not be opened, if large and bulging, it is much better to excise it." (c) One great advantage of this method of operating is its great simplicity, and the ease with which it can be performed. This was fully acknowledged by Mr. Thornley Stoker in his paper on the Radical Cure of Inguinal Hernia, in 1882, (d) in which he appeared as a strong advocate of Mr. Wood's operation. As this is the first occasion on which these operations have been brought before the Academy of Medicine in Ireland, I hardly think it will be inopportune to enter into the details of the methods of operating in the two cases.

An enema, if necessary, having been administered some time previously, the pubis is shaved, and the skin, not only at the site of operation, but all around it, is carefully washed with carbolic lotion. It is the custom in the Leeds General Infirmary, in all operations, before washing with the lotion, to rub the skin vigorously for a short time with spirits of turpentine, which appears to be the most effective solvent to the fatty and sebaceous accumulations about the hair follicles and gland ducts. (e) In carrying out this preliminary cleansing of the skin, too much care cannot be exercised, as the continued asepticity of the wound till the parts are

completely healed depends largely on this preliminary measure. The patient having been placed under the influence of an anæsthetic, the skin incision is then made, the middle point of the incision corresponding to the external abdominal ring. I have found it a good plan to draw the skin over the tumour slightly upwards before using the knife. The object in doing so is to prevent the skin wound lying directly over the twisted ends of the wire, and I am sure that this precaution will often prevent the subsequent removal of the wires, as that it will aid in the complete union of the skin wound by first intention. The skin being then retracted from over the front of the tumour, the subjacent tissues are carefully dissected until the sac is reached. If it is considered undesirable to interfere with this, it should be carefully pushed up into the abdomen by the index finger of the left hand, which, being kept in this position effectually protects the spermatic cord from injury. The edges of the rings may be refreshed or roughened by scraping; this was the plan adopted by Mr. Steele (f) of Bristol, to whom is due the credit of having been the first to put antiseptic suture in practice for the radical cure of reducible hernia, and it is advocated by Marcy, of Boston, and others. Or the rings may be seared with a red hot galvano-cautery, as advised by Dr. J. Warren, of Boston, at the last annual meeting of the British Medical Association. (g) A strong curved needle fixed in a handle and armed with strong silver wire, is then made to pass through the inner pillar of the external ring, near its apex, and at least half an inch from its free margin. It is then made to transfix the inner border of the internal ring, so as to reach the tip of the finger which lies in the canal. The point of the needle is then made to follow the tip of the finger, which is slowly withdrawn until the eye can be seen, and the wire caught with forceps. The needle is then withdrawn. It is now passed in a similar manner through Poupart's ligament, and the external margin of the internal ring at a point corresponding to its first point of entrance on the inner side. This time the needle is unarmed, and as soon as the eye is brought sufficiently far into the canal it is threaded with the free end of the wire which has already passed through the tissues on the other side of the ring. It is now withdrawn. One or two more sutures can then be passed in the same way lower down. The last one need only pass through the pillars of the external ring. By drawing the corresponding ends of the wires firmly together, the internal and external rings are approximated, the rings themselves closed, and the canal obliterated. The twisted ends are pressed down so as to lie flat against the tissues, and the skin wound is closed with catgut. I have generally employed a small drainage tube, but I believe it is only sometimes necessary. Probably a few strands of catgut or horsehair would answer equally well. Lister's antiseptic dressings are then carefully applied, and the edges kept well down by means of an elastic bandage. It will probably be unnecessary to change the dressings again for four or five days, and usually two dressings will be sufficient to complete the cure.

Sometimes the abdominal opening is so large that it is not possible even, with a good deal of traction, to approximate its edges. Mr. Croly related such a case at the meeting of the Surgical Society, in January, 1882. (h) I allude to it here in order to call attention to a method lately advocated by M. Reverdin, of Geneva. (i) He proposes to make small liberating incisions above the internal pillar, so as to facilitate the drawing of it down to the external one. These incisions are made parallel to the pillars of the ring in the aponeurosis of the external oblique. They divide these fibres into bundles, and by cutting some of the inter-columnar bands they allow the incisions to gape, and to assume a lozenge shape, which reveal the fibres of the external oblique beneath. These incisions should be short so as not to make in the abdominal wall weak points of too large size, which could allow an artificial hernia to escape; but, on the other hand, any amount of relaxation can be procured by multiplying the number of incisions. M. Reverdin has made three or four in two superimposed series, the incisions in one series alternating with those in the second. These incisions manifestly relieve tension at the points of suture, and then the pillars approach each other

more easily and exactly. One of the cases on which he operated, died eleven months afterwards of phthisis, and then it was found at the autopsy that the opening was quite obliterated. (a) In my own cases I have not yet found it necessary to have recourse to this suggestion, but should such an occasion arise, I do not think that I should hesitate to give this method a trial.

The operation here detailed of antiseptic suture of the hernial openings without interfering with the sac is of course only applicable to reducible hernia, or to cases of irreducible hernia, in which the obstruction is seated outside the neck of the sac. In a large majority of cases of congenital hernia, there is either adhesion between the contents of the sac and its inner surface, or else there is constriction about its neck. In such cases the sac must be operated on to effect a cure. It may be here observed that this method of operating seeks essentially the same results as are aimed at in the operations of Professor Wood, Mr. Dunnet Spanton, Mr. Dowell, and others; and without doubt had the discovery of the antiseptic system not taken place, these methods of *subcutaneous* closure would still hold their place as the only reliable means of treating inguinal hernia radically. But among the many changes in surgical practice which the introduction of the antiseptic method of treating wounds has effected, the method of treating hernia with a view to cure has had its share, and I do not think it is too much to expect that the method of antiseptic suture will be the adopted operation of the future. In a series of papers upon strangulated hernia, published in the *British Medical Journal* for 1882, Sir James Paget says: "I would not appear over sanguine in the suggestion of any new method for the radical cure of hernia. . . . However, I must claim a favourable consideration, on a legitimate field, for the use of the carbolised catgut ligature, at least in all cases of strangulated hernia where the wound can be closed. This method does not add to the dangers of the operation, and is probably followed by a cure. In comparing the operation with that usually recommended, of subcutaneously stitching the ring with sutures of any material, it seems apparent that to cut down upon and expose the ring, gives a much better opportunity of carefully closing it, refreshing its borders, and thus avoids injury to the spermatic cord, while it does not increase the danger to the patient."

Dr. H. O. Marcy, of Boston, (b) claims the following advantages for this operation, and I think we may fully endorse them:—

"1. We are enabled to see each and every step of the operation: *blind surgery is bad surgery*, as a rule. This want of clear perception has been the source of many mistakes by even experienced operators, and is a great objection to every form of subcutaneous sewing. In my judgment, no less can be said of the very ingenious and improved modern process of astringent injection into the ring, as advocated and practised by Dr. Joseph Warren, of Boston, in his recent work upon hernia. The same objection would hold good of Mr. Spanton's method of approximating the rings by the use of his corkscrew needle, which is left *in situ* for several days.

"2. It is the only method with which I am acquainted whereby the hypertrophied elongated peritoneal pouch, which has been a primal factor of failure hitherto, can be removed.

"3. Hereby we actually reinforce as well as occlude the ring. In the weakened attenuated condition of the parts in all old cases, there is no small gain in securing such an effect.

"4. Experience has, I think, now demonstrated that this operation may be catalogued among those safely advised, and that femoral and umbilical hernia are no exception. I would not exclude children from the class to be benefited, for in them the vital processes are at the best, and when thus cured they are saved from a life-long disability."

The following cases illustrate the operation by dissection in which the sac is returned into the abdomen unopened.

Case I.—A. B., æt. 17, a medical student, consulted me on March 28th, 1882, for a direct inguinal hernia of the right side. Previous to the 27th of that month he had never noticed any swelling in the inguinal region. He had been in the habit for a short time previously of taking long runs of six miles once a week. On the 27th of March, after one of these runs, he felt a pain in the right groin, and on examination found a hernia which had descended into the scrotum. He came to see me the next day. He then presented a tumour about the size of

a bantam's egg. Reduction was easily effected, and the finger on reaching the external ring, at once entered the abdomen without passing along the canal, the margin of the deeper opening being easily recognised. This opening was large, and the pillars of the ring in front of it were a good deal separated. I recommended the radical cure, which was at once accepted. Accordingly on the first of April, with the assistance of Mr. J. K. Barton and Dr. B. C. Windle, I proceeded to operate in the manner already described. The hernial sac was reduced into the abdomen, and the openings in the aponeurosis of the external oblique and in the conjoint tendon respectively were sutured with silver wire in two places, a small drainage tube was inserted, and the skin wound closed with catgut. The operation was performed on strict Listerian principles. The edges of the dressings were fastened down with a Martin's elastic bandage. The wound was dressed again the next day, owing to some sanious oozing, and again on the fourth day, when the drainage tube was removed. The skin wound seemed quite healed. The fourth dressing, then applied, was kept on for a week, and when removed cicatrization was complete. The highest temperature recorded was 99°. A pad was then applied, and for precautions sake the patient was kept in the recumbent position till the third week. He was then allowed up, and on the 29th day went out wearing a light truss. I have seen him several times since, and he has had no return of the hernia. Writing on the 24th of December last, a year and nine months after the operation, he says: "I cannot speak too highly of the operation and cure. . . . It has been a complete success. The silver wires with which you sutured the rings, and which you did not remove, have never caused me any annoyance whatever. . . . I may add I began to bicycle again last February, and on March 26th won a four mile race, as you will see within a year after my operation. I also engaged in about eighteen races this summer, besides doing a good deal of country bicycling, and so far from being anything the worse of the exertion, at the end of the season, last August, I gave up the truss, and have not since worn it, nor do I experience anything which would warrant a return of its use."

I had advised him to wear a light truss for the first 12 or 18 months, but I am not quite satisfied as to the necessity of it. When I last examined him, about two months ago, there was no sign of a return, and the wires could scarcely be felt beneath the skin. He has since been examined by Mr. Barton and other surgeons, who can corroborate what I have said. I may add that the patient suffered, previous to operation, from varicocele on both sides, that on the right side being the worse. The right varicocele has been completely cured by the operation performed for hernia.

(To be continued.)

Clinical Records.

CASES IN PRIVATE PRACTICE.

A Case of Croup in a girl ten years of age.—Tracheotomy.—Death.

By WM. BERRY, M.R.C.S. Eng., & L.R.C.P., & S. Ed.,
Hon. Surgeon, Royal Albert Ed. Infirmary, Wigan.

M. O., a girl, æt. 10, previously strong and healthy, was seized in the night of the 18th of Feb., 1883, with symptoms of croup. Local remedies were applied, and on Feb. 15, 1883, I was called to see her, and found that she was in bed breathing with difficulty, having all the symptoms of laryngitis. On examining the throat nothing was noticed in the shape of patches, but a general congestion of the fauces and swelling of the tonsils. She was ordered to be kept warm in bed, in a warm room and hot fomentations and poultices applied around the throat. Her bowels had been freely moved.

The following medicine was ordered:—

R. Antim. tart, gr. iss.;
Vin. ipecac, ʒiiss.;
Liq. am. a., ʒj;
Aquam, ad ʒiv.

Ft. mist. Sig.: Two teaspoonfuls every five minutes till vomiting is produced, and this repeated every four hours.
Feb. 16th.—Some relief after vomiting but laryngeal

(a) *Revue des Sciences Médicales*. Hayem. 1882. Vol. xix., p. 662.

(b) *Trans. Med. Cong.*, London, 1882, p. 447.

breathing well marked, skin freely acting and she had passed a pretty good night. Ordered mixture to be repeated and $\frac{1}{2}$ a grain of calomel with sugar every three hours. She had vomited freely several times, but no thick phlegm or membrane had been expelled.

5 p.m.—Symptoms increasing, has to be raised up to breathe, very much inclined to vomit. Ordered the following:—

R. Sodæ bicarb, gr. xxx;
Sp. chloroformi, ʒi;
Liq. amm. a. ʒi;
Aquam, ad. ʒiv.

Sig: One table spoonful every three hours. Tracheotomy recommended to parents.

9.30. p.m.—Symptoms increasing in urgency, mother having consented to the operation, with the assistance of Mr. Foreman I performed tracheotomy, under chloroform, opening the trachea without much difficulty. A lot of mucus was expelled, after clearing all this, and stopping all oozing, the tube was fixed firmly in the opening. On recovering from chloroform there was evident much relief to the breathing.

Steam was diffused through the room, and the tube cleansed with a feather through the night. Beef tea, brandy, and other restoratives ordered.

17th, 5.30. a.m.—Called to patient owing to some hemorrhage, breathing more difficult when seen but hemorrhage had ceased, tube was readjusted, the symptoms were not relieved, and she sank at 2 p.m. the same day.

On opening the trachea after death it was found to contain a good deal of mucus, with the mucous membrane reddened in patches, but no signs of membrane.

Niemeyer says in his "Practical Medicine," that croup is peculiarly a disease of childhood, and the period of greatest predisposition lies between the 2nd and 7th year, and that boys are more subject to it than girls. He says, however, that "children who have passed their seventh year may survive attacks of croupous laryngitis of the utmost intensity, but during the early years of life, croup is one of the most formidable of all diseases." Although one meets with many cases of croup every year, it is seldom met with after the 7th year, and I am inclined to believe that it is more persistent after this age and less amenable to treatment than it is in younger children. The non-success of tracheotomy in this case would not deter me from again recommending the operation, for the relief to symptoms, though temporary, is an amelioration of suffering that in itself justifies the operation.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND. MEDICAL SECTION.

A MEETING of the Medical Section was held on Friday evening, Dec. 14, at the College of Physicians, Dr. W. MOORE, President, in the chair.

Dr. A. N. MONTGOMERY, Secretary, read the minutes, which were signed.

SPECIMENS EXHIBITED BY CARD.

Dr. C. I. NIXON.—1. Abscess in Temporo-sphenoidal Lobe. 2. Scirrhus of the Pylorus.

Dr. J. MAGEE FINNY.—1. Gangrene of the Lung. 2. A Perfect Specimen of a Guinea-worm.

PROTEAN SKIN AFFECTION IN CHILDREN.

Dr. C. F. MOORE read a paper detailing a Protean skin affection. He stated that children are not infrequently attacked with a complication assuming a resemblance to pruritus cutaneous of Hebra, prurigo, pemphigus, and, in some severe cases, pemphigus gangrenosus, or burnt holes of older authors. The diseases which in Dublin had been complicated with the foregoing in varying degrees of severity were variocella, scabies, insects, dentition, certain forms of rash induced by inunction of irritating medicinal or domestic remedies, and rarely vaccination. The cases which had lately come under his notice were those of children whose ages varied from a few weeks to eight years. He did not think he had seen in this country a case of the disorder specially named prurigo of Hebra. Bad or unsuitable food tended strongly to the production of the dis-

order. The irritation caused by pedicule and other insects, and by clothing in a damp or uncleanly state not uncommonly produced pruritus sudinguis, a tedious affection of the skin. Unhealthy surroundings and a low condition of the child, or of its nurse, tended greatly to the production of the rather Protean form of ailment which he wished to bring under notice. The treatment of these cases resolved itself into general and local—better sanitary condition, better food for the child, removal as far as possible of the cause of irritation through cleanliness, and generally speaking, soothing applications; baths with bran, or tar, or liquor carbonis detergens, &c.; mild alteratives with suitable tonics; cod-liver oil or preparations of iron. In all cases inquiry should be made for the presence of intestinal worms, and the treatment suitable pursued. The affection which seemed allied to prurigo, pruritus, and pemphigus, occurred in eight cases that were originated apparently by variocella; in four cases where scabies existed previously; in one case in which tallow had been used as a domestic remedy by inunction; and another in which a very slight appearance of prurigo cutis existed. The latter ailment was apparently increased after vaccination. The cases that had come under his notice had occurred almost invariably in the cold spring or early winter. He did not refer to the many cases of pruritus and prurigo that he had seen in the adult and in youth. The affection noticed by Mr. Hutchinson, of London, as variocella prurigo, and regarded by Mr. Balmanno Squire rather as ecthyma or lichen urticatus, seemed to resemble cases which he had seen in Dublin, but which were of a very Protean character, and did not generally assume the serious forms described by Mr. Hutchinson or by Prof. Hebra in describing the life-long character of the prurigo met with at Vienna.

Dr. H. C. TWEDDY described the case of a boy, aged 16 years, who had come under his observation, presenting the features of true prurigo, which he had had since childhood, and which resisted all treatment.

Dr. DUFFEY said Dr. Moore had described several skin affections, but had not specified the particular one which he considered now prevalent. It was a common thing to find eczema on the soles of the feet and palms of the hands in infants.

Dr. FITZPATRICK considered Dr. Moore had combated the idea that vaccination was a cause of skin disease. He did not believe that pure vaccine matter would produce skin disease in a healthy child.

Dr. MOORE, in replying, was glad to find that Dr. Fitzpatrick's extended experience confirmed his own opinion that vaccination in itself was not a cause of skin disease.

A CASE OF PULSATING LIVER.

Dr. WALTER SMITH reported a case in which he had observed true regurgitant throbbing of the liver in connection with mitral valve disease. A soldier, æt. 35, had suffered from cough and breathlessness for three years. When admitted into hospital the legs were anæsthetic, and the lungs engorged. There was a systolic apical cardiac murmur. There was extreme dusky congestion of the face and hands, and the jugular veins, which were of immense size, pulsated visibly. The urine was albuminous. The liver extended 2½ in. below the ribs, and a distinct expansile pulsation of that organ, extending over right and left lobes, could be seen and felt. The man left hospital after a stay of some weeks. He was admitted shortly afterwards under another physician, and died suddenly. No post-mortem examination was held. Dr. Smith drew attention to the comparative rarity of hepatic pulsation as a well-marked sign, and discussed its causation and bearing upon the diagnosis of tricuspid regurgitation. It was suggested as probable that in nutmeg liver there is commonly some degree of hepatic pulsation, but in many cases this is very feeble, and therefore inappreciable to ordinary methods of examination.

Dr. WALLACE BEATTY said the patient only lived a few hours after his re-admission to hospital, and during that time the liver did not pulsate.

The PRESIDENT mentioned a similar case which had come under his notice three years ago, in which mitral stenosis with dilatation existed, together with a visible jugular pulsation, called post-systolic pulsation.

Dr. C. I. NIXON thought it would be difficult to distinguish between an eccentric pulsation of the liver due to regurgitation of blood into the hepatic veins and that general pulsation which the liver in a state of extreme congestion might receive from a pulsatile condition of the inferior vena cava.

Dr. SMITH, in reply, admitted the force of the point raised

by Dr. Nixon. Still, it remained a question why those cases were not observed in Dublin as they had been in London and Newcastle.

BRACHIAL MONOPLÉGIA WITH ANÆSTHESIA.

Dr. C. I. NIXON, having exhibited the patient, read the notes of a case of partial motor paralysis of the left arm occurring in a girl, æt. 19, who was under his care in hospital. The chief points of interest in the case were shortly these: The girl had been engaged washing clothes in very hot water in May last, when she remarked her hand and forearm becoming numb. Next day the numbness had extended up to the shoulder, and the entire arm became powerless. Shortly afterwards the numb feeling extended upwards to the left side of the neck and face, and downwards over the left half of the thorax. She was admitted into hospital. The notes of her condition were made, as follow:—*Motor function*.—Partial paralysis of left arm were more marked in movements of wrist than in those of elbow, while there was least apparent power in the shoulder. No rigidity of any kind was observed in the movements of the limb. *Sensory function*.—Complete tactile anæsthesia over left arm, left side of face, including left ear and left half of thorax. Common sensibility was affected to a very considerable degree. The patient bore on this arm the passage of a needle through the skin, the application of a heated iron, the most severe pinching, and the application of the induced current without manifesting any expression of pain. *Temperature*.—The temperature of the left arm was sensibly colder than that of the right. Its aspect was considerably altered from the normal state, being of a dusky bluish colour. There were some evidences of trophic disturbances in the occurrence on the fingers of the left hand of patches like chilblains. There was a marked ischæmic condition present over the anæsthetic parts. *Sight*.—There was no alteration in the patient's left fundus oculi. The cornea was completely anæsthetic. There was no achromatopsia. *Hearing, taste, and smell* appeared to be unaffected. In discussing the points of interest in connection with the case, Dr. Nixon dwelt upon the impossibility of connecting the lesions observed, especially the irregular distribution of the anæsthesia, with any localised central lesion; so that he was obliged to regard the case as an instance of the curious manifestation of the great neurosis hysteria. In this case, however, there were none of the usual antecedents or concomitants of the hysterical condition. The family history of the girl was very good, there being a complete absence of any trace of nervous development in the parents or in her brothers and sisters. The girl's generative system was in no way affected. She had no evidences of exalted sensibility in any part, and her disposition was the opposite of that usually observed in hysteria.

Mr. STORV corroborated Dr. Nixon's account of the girl's eyes, except that when he examined her the lachrymal secretion was the same in both eyes.

Dr. WALTER SMITH thought that the sudden disappearance of anæsthesia did away with an intercranial origin for the disease.

Dr. FINNY mentioned a fatal case of acute ascending spinal paralysis in which post-mortem examination failed to exhibit any gross lesion to account for the symptoms.

The PRESIDENT, Drs. H. KENNEDY, J. J. MURPHY, A. BENSON, and JAMES MARTIN having also joined in the discussion,

Dr. NIXON replied.

The Section then adjourned.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, DECEMBER 3RD, 1883.

JOSEPH WALKER, M.D., PRESIDENT, in the Chair.

MR. J. B. SUTTON showed a remarkable case of absorption of the hard palate, &c., as the result of long continued pressure. The patient had suffered from perforation of the hard palate of syphilitic origin, and for many years before his death he had been in the habit of closing this opening with rags, increasing the size of the plug as the opening became larger, until the following state of things resulted: The anterior three-fourths of the hard palate, with the whole of the alveolar arch and teeth had entirely disappeared; the antra, nasal fossa, and mouth formed one large cavity, bounded laterally by the thin outer shell of the superior

maxilla, and above by the orbital plates of the maxilla, the superior and middle turbinate bones, and the cribriform plate; the nasal septum was almost completely gone, and the left lachrymal bone had disappeared.

Several other interesting specimens having been exhibited, the discussion on Mr. HENRY POWER'S paper on

THE RELATIONS BETWEEN DENTAL LESIONS AND DISEASES OF THE EYE,

read at the previous meeting, and which has already appeared in this journal, was resumed.

Mr. MACNAMARA spoke highly of the value of the paper, which he believed to be the most complete collection of facts bearing upon this important subject which had yet appeared in the English language. Cases were not unfrequently met with in which atrophy of the optic nerve on one side occurred without any apparent cause—there was no local inflammation, and no evidence of any central lesion. These cases were very puzzling to ophthalmic surgeons. In future he should always carefully examine the teeth. If it should be found possible to arrest these cases of amaurosis by extracting a few teeth it would be a most important discovery, and he thanked the author of the paper for calling his attention to this possible cause.

Mr. S. C. GIBBONS, of Brighton, mentioned the case of a young lady who after suffering for eighteen months from greatly impaired vision, said to be due to amaurosis, applied to him and had a number of dead and decayed teeth extracted. Improvement in the sight took place at once, and in the course of a few weeks it was almost as good as ever; one eye, however, remaining a little weak.

Mr. SMITH TURNER thought the subject of the paper concerned the ophthalmic, rather than the dental, surgeon. The latter might assist the oculist by pointing out sources of dental irritation which might escape the notice of his colleague, and would of course have the chief share in carrying out the treatment thus indicated, but as the diagnosis and treatment of diseases of the eye required special knowledge and experience, it was evident that such cases as those referred to in the paper must be dealt with mainly by the oculist.

Mr. SAVORY remarked that Mr. Power's paper called attention to a most important principle which was constantly in action in all parts of the body both in health and disease, viz., that intimate connection between different, and often distant, organs which was commonly referred to under the name of sympathy. The fact that the cause of disease might be in one part of the body and the signs of it in another was one which should be constantly kept in mind, though it was, unfortunately, constantly forgotten.

Mr. CHARLES TOMES said it had generally been thought that remote nervous disturbance was more likely to occur when the living tooth pulp was irritated. But he found that in most of Mr. Power's cases the tooth was dead, consequently the source of irritation was external to them, and must have acted directly on the trunk of the dental nerve, which lay in close proximity to the roots of the teeth, and not upon its terminal filaments. He thought this was an important point and worthy of attention.

The discussion was continued by Messrs. Hunt, S. J. Hutchinson, Storer Bennett and others, after which Mr. Power replied and the President adjourned the meeting.

Special Articles.

MEDICAL ORGANISATION IN WAR.

ON Friday last a paper was read at the Royal United Service Institution by Surgeon-Major Evatt, M.D., of the Army Department, upon the question of Army Medical Organisation in War. Surgeon-Major Longmore presided.

Surgeon-Major EVATT said that the subject had received little attention from officers, and he had failed to find a general knowledge of medical wants infused in the Service. An army existed for war, and if it failed in that duty it was a sham, and had better be cleared away. He maintained that in 1853 the system of medical service so far as war was concerned—and it was tested by war—was a sham. Twenty years later important changes were made in the system of medical treatment in

war, and a new organisation in the shape of the bearer-company was instituted. He claimed for the bearer-company that it was the very best and the most useful outcome of modern humanity in dealing with wounded men in war. As regarded field hospitals there were in 1854-5 47 regimental hospitals, fragile creations, without trained nurses, without their own quartermasters, and completely organised to break down when left behind by the advancing regiment. These 47 fair-weather yachts had been replaced by 25 field hospitals, complete units in themselves. Remarkable improvement, however, had taken place, and the medical service was striving to force upon the army a system of war organisation framed to assist the fighting soldier to achieve success. It was perfectly well known where and how our armies had broken down. They had broken down in the departments—in the Commissariat, in the Transport, and in the Medical services. This would always be the case until all inequalities in the treatment of the various classes of officers in the service were crushed out with a firm hand, and every man, from the highest to the lowest, felt that all were working for the same end.

Lord CHILMSFORD thought that all who had considered the question of military treatment in the field would agree that the position of the Medical Department was not at present sufficiently clearly defined. If one looked back in order to see who was primarily responsible for the defects, it would be found that it must be the Government. Liberal or Conservative, both parties were afraid to go to the country to ask for the requisite amount of money, so as to keep the army up to such a state of efficiency that it would be ready when war broke out. It was very unfair that the Medical Department should be required to look after the sick and wounded when it was not given the proper means of doing so, and he took it that as to the last campaign, to which allusion had been made, it was simply the fault of the country at large that it had not made sufficient provision, so as to enable the Medical and Commissariat Departments to be really placed in the proper position to perform their important and necessary duties efficiently.

A vote of thanks was passed to Major Evatt for his paper.

TUBERCULOSIS EXPERIMENTALLY AND MYCOLOGICALLY CONSIDERED.

DR. A. WEICHELBAUM, of Vienna, recently read a paper on the above subject, and as it is an important one, going as it does over the ground, step by step, traversed by Koch before he arrived at his present views, and as it also goes over the experiments of Spina, and as, moreover, so very few workers have taken the trouble to do this, we think some account of it will be acceptable to our readers.

The writer first shortly reviewed the experimental part of the subject, in the course of which he particularly described the experiments of Villemin, Waldenburg, Cohnheim, Tappeiner, and himself. From these latter it appears that the inhalation of tuberculous sputa by dogs is always followed by nodules in the lungs, bronchial glands and kidneys, and that these nodules correspond anatomically and histologically to human tubercle, and that they constantly contain tubercle bacilli, whilst after the inhalation of non-tuberculous substances either none at all, or but very few nodules are produced in the lungs, and these do not contain tubercle bacilli, and cannot be looked upon as really tubercular. Moreover, the injection of tubercular sputum into the abdominal cavity invariably sets up a disease which exactly corresponds to human peritoneal tuberculosis, whilst non-tubercular substances produce no effect. The speaker

remarked that before Koch the inoculability of tuberculosis had been experimentally proved, or at least shown to be highly probable, but that it was through this investigator that it had been first indisputably proved that tubercle was inoculable, by his discovery of a well characterised bacillus by the pure cultivation of this, and by the inoculation of it into the most varied species of animals, setting up that form of disease that usually follows the entrance into the system of tuberculous substances.

The labours that followed Koch's discovery were usually limited to the proof of the tubercle bacilli in the sputum, and to the method of colouring employed in the identification of the bacilli. Only Spina had undertaken to prove the results of Koch's investigations throughout their whole course. As Spina's have already been made public in our columns it is not necessary to recapitulate them on the present occasion.

Weichselbaum had not only repeated the experiments of Koch throughout their whole course, but also those of Spina and the conclusion he arrived at was, that those of the latter gentleman were altogether erroneous. He maintained (1st) that by employing the aniline colouring matter in the proper manner the bacilli of Koch were distinguishable from all others; that (2nd) their constant presence could be proved not only in tuberculous sputum, but also in tubercle of all organs, therefore also in those excluded from the air, as well in cases of acute as of chronic tuberculosis, whilst they were as invariably absent in non-tuberculous products and fluids. As proof of this sections of tuberculous omentum and seminal vesicles were shown which contained tubercle bacilli in great numbers.

He considered that Spina's results could only be explained on the assumption that he was not master of the art of colouring the specimens, and that his investigations were made without suitable optical aids (oil immersion and Abbé's light). In regard to Spina's cultivation and inoculation experiments, there was a great want of proportion between the numbers of Koch's and those of Spina. Moreover, he did not fulfil the most elementary conditions of a successful cultivation—he did not make use of a suitable and sterilised nutrient material; the blood serum employed by him was neither sterile nor suitable for cultivations, as progressive shrinking showed. It was on this account that in Spina's cultivations plain evidences of decomposition were manifest, and dried colonies of decomposition bacteria made their appearance.

The speaker had himself made cultivation experiments, but his results entirely coincided with those of Koch. At the commencement, and before the necessary technical skill had been obtained, failures were almost unavoidable, it was only by repeated experiments that one learned to know the sources of failure and to avoid them, and then correct results could be obtained. Samples of properly prepared blood serum, and of the serum employed by Spina, were shown and their cultivated bacilli and air germs which could fall on the serum on the opening of the eprouvette.

The speaker then showed that the changes induced in animals on the introduction of tuberculous products and cultivations into their bodies was a true tuberculosis, which could never be produced by any other substances, provided that accidental tubercular inoculation were avoided. Although nodules might be produced by the injection of fluids containing exceedingly fine particles, yet these nodules so produced were essentially different from true tubercle, from those nodules that were the result of inoculation by tuberculous substances. They did not show either the

peculiar regressive changes of true tubercle, nor growth, nor increase, they were confined to the point of inoculation, and their numbers were always in direct proportion to the number of solid particles in the fluid injected; moreover, they never contained tubercle bacilli. The speaker illustrated his points by demonstrations of guinea pigs into which the seeds of lycopodium, carmine, catarrhal sputum, bacteria from air germs cultivated in blood serum, tuberculous sputum, and tubercle bacilli obtained by cultivation had been injected. He contended, in conclusion, that there was nothing in the pathological anatomy of the disease, nor in the clinical history of it that was opposed in any way to the parasitic idea of tuberculosis.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 23, 1884.

CATHETER FEVER.

THE highly-important considerations mooted in Sir Andrew Clark's address on catheter fever continue to attract considerable attention from surgeons, who are manifestly aroused to the necessity imposed upon them to render more satisfactory explanation than any hitherto advanced, to account for the phenomena in question. Notwithstanding, however, that much earnest thought and skilled observation have been brought to bear on the issue, it still remains to be said that Sir Andrew Clark's main facts are unimpugned, although some more hasty generalisations indulged in by him have been modified as a result of further discussion. That many of the statements which have been made are not altogether supported by actual occurrences, may be at once accepted as true; and also that full advantage has not been taken of previous work done in connection

with the subject of controversy; but in return for so much of omission as has to be counted to the discussion we have obtained an amount of information that will enable future workers to relieve themselves of the labour of a good deal of preliminary investigation. In a recent number of this journal we described the views enunciated by Dr. Roberts Bartholow respecting the existence of a form of reflex paralysis excited through irritation of the intestinal canal, and denominated by him "enteric paralysis." Such methods of explanation as were adopted in that paper may with equal forcibleness be imported into the discussion on catheter fever, for in both conditions we have to deal with essentially similar causes and results. In this connection, moreover, it is interesting to recall the substance of a paper communicated in April, 1882, to the *Lancet*, by Mr. A. T. Norton, F.R.C.S., in which the pathology of so-called urethral fever is very clearly laid down, and an explanation of the obscure effects sometimes observed after it. Answering the question, "What is urethral fever?" Mr. Norton states that "it is a reflex paralysis, or, in other words, it is an exciting impression upon, or injury to, a set of peripheral nerves, which, by reflexion through a centre, may result in paralysis of the whole, or a part, of the united cerebro-spinal and sympathetic nervous system, either transient in character, or ultimately through the vaso-motor system, bringing about structural change or suppuration in organs or other tissues." It is highly instructive to note how the same idea has presented itself to other practitioners, as it has to Sir Andrew Clark, who, far from being the first to dwell upon the general principles of the subject, has, as he takes care to explain, been preceded by many observers of the phenomena he describes. Thus, Mr. Norton commences the clinical lecture to which allusion is made above with the following words, to which, in the light of recent events, an unusual amount of significance must be attached:—"Again and again have I known catheterism to be followed by a rigor and an elevation of temperature to over 103° by the following morning. . . A fever so induced would be transient in a subject otherwise healthy, but it would not be so in an unhealthy person with any organ or part already predisposed to inflammation; and more especially might unfavourable signs be expected to present themselves in that part or organ more closely allied to the injured part, such as the kidneys in their relation to the bladder and urethra." In illustration of the principle thus laid down, the author then goes on to detail the history of two cases, in one of which catheterism was followed by a temperature as high as 105°, with most grave symptoms of impending death, which, however, was at length happily averted. In another case closely resembling these, but in which perineal section had been performed, death did occur, a temperature of 106°, with rigors, having been noticed in it. *Post mortem*, only general congestion of the organs was found, without any structural lesion of the kidneys.

But whatever coincidences may be discovered in regard to observations made by different workers, it remains that the principal object now in view is to find a sufficient explanation of the facts about which little

disagreement really exists. Sir Andrew Clark is undoubtedly right in asserting that some subjects of catheterisation do die under the fever induced by the operation, simple though it is; and that no evidence of a kind gross enough to account for the catastrophe is afterwards discoverable in those organs which would be first suspected as seats of lesion. In what way, then, is the result produced?

Reflex irritation of the nervous system, leading to the most widespread alterations of function, and arising from almost trivial causes, is now a well-recognised phenomenon in medicine; and probably the importance attaching to it as influencing the progress of many obscure diseases is likely to assume yet greater proportions in the future. Returning once more to Mr. Norton's paper on urethral fever, we would make this further quotation from it: "When the irritant is in the urethra or bladder we have a variety of results, depending very much upon the extent and duration of the irritation, and also upon the diathesis of the patient. As a result of passing the catheter, we have in one case high temperature for a few hours only, or perhaps the development of a crop of herpes, with albuminuria, lasting for a fortnight or three weeks; in another case paresis or paralysis of one or more sets of nerves, or even of the whole nervous system, or perhaps complete unconsciousness, with high temperature, 106 deg., and death will take place in a few hours." One of the cases cited in the article was completely paralysed on one side after catheterism, and during the illness a large amount of albumen was passed in the urine; but recovery ultimately took place, notwithstanding the very serious nervous disturbance manifested by the symptoms observed. In those cases which terminate rapidly, and which are not to be accounted for by the presence of gross kidney lesions, it is to be assumed that a reflex vaso-motor paralysis is induced as a consequence of irritation of the urethra by a catheter; and we do not need to hesitate about accepting the truth that in certain diatheses a widespread disturbance of this description will suffice to entail disastrous results before time enough has elapsed to permit the production of recognisable structural changes in the organ first suspected—the kidney. How profoundly the state of the body may be affected by paralysis of the vaso-motor system for any length of time is very generally understood by physicians in this age, but we have yet to obtain the full and complete *rationale* of the process whereby so speedy a fatal termination is determined as sometimes occurs in cases of the class instanced by Sir Andrew Clark. Possibly such explanation will be sooner or later forthcoming; its advent will certainly be hastened by the very valuable discussion now in progress as a result of the address on catheter fever.

TRICHINOSIS.

The account of an epidemic of trichinosis in Germany, reported in the last number of the *Deutsche Medicinal Zeitung*, is of more than passing interest to readers on this side of the Channel.

The three villages attacked are situated in the neigh-

bourhood of Halberstadt, one of them (Emerleben) having a population of 760. It is stated that the people of the district have for years followed the bad custom of eating a considerable quantity of raw, chopped pork, especially the field workers, who consume the meat on bread or bread-and butter, out of doors, instead of going home to their midday meal. On the 14th and 15th of September last a considerable quantity of raw, chopped pork was as usual consumed, all of it being furnished by one butcher. The first symptoms of illness made their appearance, in some cases, on the first day, as nausea and vomiting, and on the second day in the form of diarrhoea. The first cases came under treatment on the 20th, more from the 20th to the 30th, and the last on October 15th. The last was an old woman, aged 63, who would not submit to treatment until her married daughter and grandson had died of the disease. The first symptoms then consisted of vomiting, diarrhoea, pains in the stomach and bowels, great thirst, and fever. Temperature, 38° to 41° C. In the succeeding days the vomiting ceased, but the diarrhoea continued, but not to so great an extent. From the fifth to the seventh day the diarrhoea also ceased, and then pains in the limbs came on, pain on pressure in the upper arms, thighs, and calves, and great stiffness, but the chief feature was cedema of the eyes and of the face generally. The symptoms continued the same till typhoid appearances were added to them—sleeplessness; dry, furrowed tongue, with a brown coating; delirium; and, instead of the diarrhoea, constipation in many cases. The cases were frequently complicated with pneumonia, pleurisy, meningitis, herpes zoster, aphthæ, &c. Often, after weeks of illness, the cedema of the hands, legs, breast, belly, and limbs grew worse; on the thighs and labia the skin cracked, and made lying painful. Erysipelatoid inflammation of the skin—in one case gangrenous sloughing of the prepuce—increased the sufferings of the patients. Those cases were the worst in which the tongue, larynx, and pharynx were thickly strewn with trichinæ, as in these feeding became a matter of difficulty, and the air on inspiration was very cutting. The first death took place on October the 3rd, when a man, aged 25, who had eaten the trichinised meat on September the 15th, died. The official post-mortem examination revealed numberless intestinal trichinæ, and wandering parasites were found in the diaphragm and other muscles, but not in such great quantities as later on, when the reporter found thirty in one preparation partly encapsuled and partly free. The greatest number of fatal cases occurred in the fifth and sixth week, when ten and eleven died respectively. The total number of persons affected amounted to 257, of which number 50, or about 20 per cent., were dead at the date of the report. The greatest age at which the disease proved fatal was 76, and the lowest 12. Children were rather numerously attacked—the youngest was 1½ years old—but none under the age of 12 died. Of the fatal cases, 20 were males and 30 females. The first wandering trichinæ were met with in a body on October 6th—the first encapsuled in a woman 60 years of age, who died on October 30th—in the sixth week—and in this case nu-

merous free muscular trichinæ were also found. This patient had eaten the trichinised flesh on September 15th. In the ninth week also, along with encapsuled trichinæ, free trichinæ were found. Persons who had eaten the diseased flesh roasted, cooked, or as liver and red sausage, suffered eight to fourteen days, some as long as three weeks, from stiffness of the limbs; and some, diarrhoea and swelling under the eyes, but they were not confined to bed. No medicines employed were of any avail. Those who had eaten as much as 1½ lb. of the trichinised flesh, with few exceptions, all died. Ergotin, glycerine, &c., were employed. It was mainly the symptoms that were treated. Quinine, chloral, lumps of ice for swallowing, and—as outward applications—muriatic acid, phosphoric acid, camphor, morphia, and acetic ether, were employed internally, and as injections. Three households were completely killed off; in two, four persons died in each, and three in the third. In the second village, Deesdorf, with about 650 inhabitants, a good deal of chopped pork was disposed of, and about forty persons sickened, of whom nine or ten died. The butcher took none of the meat to Nienhagen—the third village—till Sunday, September 16th, and there more than eighty persons sickened, but none died, the reason being that but little of the trichinised meat found its way to this place, as the diseased meat that was sold there was mixed with sound pork from a later killing.

The French Minister of Commerce sent a special Commission, under M. Brouardel, to report on the various phases of the epidemic, and this gentleman submitted his report to the Academy of Medicine at its sitting of December 26th. The following are the principal conclusions contained in the report:—1. The cooking of the pork secures an absolute immunity to the consumer. 2. The time that elapses between the moment at which the trichinised animal is killed and that in which the flesh is eaten has a considerable influence on the intensity of the accidents that may follow its consumption. The longer this interval is, the more the accidents lose in point of gravity. Of those individuals in Emerleben who ate of the raw chopped meat the day after the slaughter of the animal, 33 per cent. died; whilst of those who ate of it six days afterwards none died. 3. The examination of the pork for trichinæ—easy when the animal is not yet cut up, and when the examination is made by competent inspectors (microscopists)—is tedious, difficult, and may be unfruitful as soon as the possibility is not given them of seeking the trichinæ in their favourite sites; it is useless when the consumers, in addition to the examination, do not secure absolute immunity by cooking the meat. 4. The study of this epidemic has convinced the Commission that no such severe cases of trichinosis have up to the present been seen in France.

Upon making inquiry as to whether human trichinosis had ever been traced in Germany to the consumption of American pork, the Commission were assured by Drs. Virchow and Hertwig that, notwithstanding the German custom of eating the American pork raw, no case of human trichinosis could be traced to it.

It will thus be observed that in no case did the disease

prove fatal in which the flesh had been first cooked, and the epidemic was entirely brought about by the disgusting habit so prevalent in many parts of Germany of eating raw pork. We have never heard that such a practice attains in this country, and therefore we do not run the same risk of an epidemic of this nature. But the habit of eating uncooked ham is exceedingly common, and the public must be cautioned that the process of curing this delicacy, whether by smoking or drying, in no sense serves the purpose of cooking, nor is it sufficient for the destruction of these dangerous parasites when embedded in its fibres.

HOSPITAL ACCOMMODATION FOR NORTH LONDON.

AN important and influential meeting was held on Saturday last, at the Athenæum, Highbury New Park, in furtherance of a scheme to provide the North of London with some sufficient hospital accommodation. The chair was taken by the Duke of Westminster, who, after dwelling on the necessity of the movement for providing the eight or nine hundred thousand inhabitants of North London with an hospital situate in the neighbourhood, pointed out that an amalgamation had been arranged between the Committee of the new scheme and the Committee of the Great Northern Hospital, in consequence of which about £4,000 already subscribed by the work of collecting, and for subsequent support of the public became available. Rightly enough, the noble Chairman insisted that this was but a small part of the necessary amount to be raised, but he advocated pressing on with institution to trust to chance. He recommended the meeting first of all to beg or buy the site and then build their hospital, and having been somewhat reckless in that respect they might leave the maintenance to take care of itself, with this reservation, that payment should, in certain cases, be demanded from the patients who were able to pay something towards the great advantages they would receive from the hospital. It was not for a moment intended that the hospital should not be a free one in many respects, but he considered the principle a good one that those who could afford it should pay something, if not the whole, for that which they received.

Such a suggestion at the present time, coming from such a source, is hardly calculated to carry encouragement to the minds of those who are familiar with the sore straits to which all of the great hospitals depending on public charity have lately been put, nor is it at all more comforting to know that Lord Salisbury, who followed the Duke of Westminster, practically endorsed the appeal made by the latter, and stimulated popular confidence in hospitals at the expense of private practitioners. A number of other gentlemen addressed the meeting, the general strain indulged being that entered on by the chairman's introduction, and eventually the following resolutions were unanimously adopted:—

"That this meeting, fully recognising the want of additional hospital accommodation in North London, warmly approves the arranged amalgamation of the Great Northern Hospital and the Central Hospital for North London, as being the best means of providing for that necessity."

"That in accordance with the said arrangement, the

following shall be the constitution of the new united hospital:—I. The name of the hospital shall be 'The Great Northern Central Hospital.' The hospital shall be a general and free hospital, with pay wards or a pay wing. II. The governing body shall consist of a president, vice-presidents, a general council, composed of (1) the existing life governors of the two hospitals, (2) life members, being donors of thirty guineas and upwards, (3) members annually subscribing three guineas and upwards, (4) members representative of congregations, corporations, companies, firms, and workshops, with similar qualifications."

A further proposal was adopted to open subscription lists in furtherance of the objects of these resolutions, and to obtain a building fund, and as a result of the whole affair we may probably expect to see the desired hospital added sooner or later to the list of impecunious charities appealing to public sympathy for relief from the pressure of an empty purse. That the outcome is satisfactory can hardly be said. Doubtless the poor of North London are placed under disadvantages in sickness; but it is questionable if they do not obtain all the aid absolutely necessary to them through existing hospitals; and at this stage of the new movement, though approving the general principle of its promoters, we do not feel able to speak enthusiastically about it.

Notes on Current Topics.

Housing the Poor.

WHATEVER may ultimately result from the very general interest excited in the condition of indigent poor of large towns by the numerous articles and speeches on the subject which have appeared within the last few months, one thing, at any rate, has been made clear, namely, that the powers already conferred by Acts of Parliament for the purpose of improving poor neighbourhoods have been very inadequately put in force hitherto. On this point, an article in the current *Westminster Review* deserves especial attention, and may be the means of awakening action in many quarters where action is sorely called for. The writer of this article shows that there are in existence several Acts containing clauses which are expressly drawn to enable ordinary ratepayers to make such representations respecting the unfitness of tenement houses for dwelling purposes as shall result in their owners being compelled to put them in repair; or failing this they shall be either restored at the public expense and the amount recovered by compulsory sale or otherwise, or purchased by the local authority. The practical conclusion arrived at in the paper is that improvement in the dwellings of the poor should be secured without the assumption by the State of a landlord's functions; and that private philanthropy should be so organised and directed, as has been so ably done by Miss Octavia Hill, as to obtain a fair percentage in the shape of interest on the outlay entered on with a view to remodelling rookeries. Only by one or other of these agencies can the present state of misery be overcome, with all the attendant evils of insanitation, sickness, destitution, and death.

Hystero-Epilepsy complicating Pregnancy.

DR. W. H. SHIPPS recently communicated to the Obstetrical Society of Philadelphia a most interesting narrative of a case of pregnancy complicated by daily attacks of an epileptiform character, and an account of which appears in the *Obstetric Gazette* for December, 1883. When first seen the woman was three months advanced in gestation, and was violently struggling, examination showing perfect unconsciousness, wide open eyes and dilated pupils, frothing at the mouth, which was tightly closed, and a full, bounding pulse. She was eighteen years old, and prior to this seizure had undergone one or two similar attacks, though of less severity. One-third of a grain of morphia injected hypodermically controlled the fit, a state of stupor supervening, followed in three or four hours by total recovery of all powers. For the next two hundred days, at least one paroxysm *per diem* was noted; sometimes the epileptic fit would ensue without warning, at others it would be preceded by distinct hysteria; but in every case, Dr. Shipps observes, the imprint of the dual disease, hystero-epilepsy, could be discerned. The patient, in the inter-paroxysmal periods, enjoyed good health. On September 23rd a more than usually grave attack occurred, and unconsciousness was maintained for many hours, notwithstanding efforts made to combat the condition, and the next day labour commenced at 7 a.m., a healthy female child being delivered at 3.45 p.m. Throughout labour, however, constant vigilance was needed to prevent the woman from falling into one of her accustomed attacks, and subsequently her whole force of will was required to prevent their recurrence; but no repetition afterwards took place, and both mother and child did well. During the entire period the patient was under observation large doses of bromides and other nervines were prescribed unavailingly, save to influence the possible severity and number of the paroxysms, which Dr. Shipps attributed to reflex action exerted by the fœtus *in utero* on the maternal brain and spinal cord. On the question whether premature labour should be induced in the rare class of cases exemplified by his patient, he expresses the opinion that such a course, on theoretical grounds, ought to be followed, and that should he be called on to treat another such, he would procure abortion, in the expectation of most gratifying results. The case is a very interesting one, and may well deserve careful consideration.

OWING to a continuance of the mild spring-like weather the mortality throughout the United Kingdom presents a very favourable record. In the large towns last week the deaths corresponded to an annual rate of 21.0 per 1,000 of their aggregate population. The death-rates in the several towns were:—Portsmouth, Leicester 13; Bristol, Derby, Wolverhampton, Plymouth 17; Edinburgh, Preston, Huddersfield 18; London, Hull 19; Birmingham, Blackburn, Sunderland 20; Nottingham, Birkenhead, Bradford 21; Brighton, Salford, Halifax, Newcastle-on-Tyne 22; Liverpool 23; Cardiff, Bolton 24; Glasgow, Sheffield 25; Dublin, Oldham 27; Manchester, Leeds, Norwich 28.

An Ovarian Tumour Tapped Seventy-seven Times.

In the *Nashville Journal Med. and Surg.*, August, 1883, a case is reported by Dr. Jasper Goodson, of a woman, *set.* fifty-six, a widow, and mother of five grown children, having been subjected to tapping seventy-seven times for ovarian dropsy, at intervals of from fourteen to twenty days. Four gallons of fluid has been the smallest quantity of fluid drawn off, and altogether as many as four hundred and ninety-seven and a quarter gallons were evacuated. Her general health and appetite are excellent; she suffers only from the immense size the tumour attains to before relieved by tapping. She has declined to submit to ovariectomy. The case is interesting, showing the great tolerance of such interference on the surgeon's part, and for the good state of health the patient enjoys, in spite of the great drain on the system.

Our own experience is, that tapping with a No. 3 trocar for any collection of fluid, is a very harmless measure if properly done. In one case we tapped a woman, with a No. 3 trocar, twenty times without producing a bad symptom. She then passed into a hospital, where theappings were repeated, and the woman made an excellent recovery.

Many other instances of repeatedappings have come under our notice, in which marked benefit in some and recovery in others, have evidently attended upon this operation frequently repeated. Connected with this subject of tapping may be noticed, the great and decided benefit that attends free puncture of the legs in anasarcaous dropsy. Twenty to thirty punctures in each leg, drainage being promoted by warm fomentations. This measure frequently turns the balance, and enables diuretics and purgatives to take full effect.

Rainbows.

As announced in our last issue, Prof. Tyndall delivered a lecture on Rainbows, which will be long remembered by all who were privileged to listen to it. That the learned doctor is one of the most original thinkers and experimenters of the age no one will deny, and his last Friday's discourse at the Royal Institution will, we think, be conceded as one of the most interesting with which he has favoured the scientific world. He commenced by treating his subject historically and experimentally. Rapidly sketching the researches, among others, of Descartes, Newton, and Thomas Young, he showed how we have arrived at our present exact knowledge of the primary and secondary rainbows, explaining the refraction of the rays of light from drops of rain, and illustrating his observations by means of diagrams. The experiment which gave such unbounded pleasure to his audience was undoubtedly the shower of filtered water which was caused to fall in the darkness through a very fine "rose," and upon it was thrown a beam from an electric light. Clad in oilskin, Prof. Tyndall entered the shower, and, with his back to the lantern from which the light was projected, he peered through the falling particles of water, and stated that there was visible a perfectly-formed primary bow and secondary bow, with "supernumerary" bows. Puffs of steam from a boiler, with the light similarly thrown upon them, disclosed a bow; and next a shower of spray from

an appliance such as is used in the House of Commons to render the atmosphere humid was caused to descend through the beam, with the result of showing a white bow—rarely seen in Nature. The lecturer, when on his rambles, saw one last Christmas, having previously noted, after a fog, that the air was full of white specks. It was a perfect white bow, and he accounted for its hue by the specks being too small to give off prismatic hues. This theory he demonstrated by the experiments described—the shower from the fine "rose" discovering prismatic hues, and the spray, which descended as a mist, so fine were its particles, forming the white bow. In order to confirm these experiments, if such were wanted, the lecturer requested one of the audience to don the oilskin, and he was rewarded for his trouble by seeing all that had been so eloquently described.

Epidemic Croupous Pneumonia.

DR. BADMANOW, of St. Petersburg, reports having observed 134 cases of pneumonia in a Russian infantry regiment, 1,200 strong, within a very limited period during the past year. Thirty-one of these occurred in 1882, and the remainder in 1883, the whole number—103—being met with in the first five months of the year—viz.: 2 in January, 25 in February, 39 in March, 26 in April, and 11 in May. The men were occupying damp and not sufficiently roomy barracks. From the time the quarters were changed, no more cases occurred. The recruits were as much affected as the seasoned soldiers. The mortality amounted to 12.6 per cent. During the same period—January to May, 1883—22 cases of erysipelas also occurred.

Dr. Rogers and the Local Government Board.

OUR readers will remember that a few weeks since we announced that Dr. Joseph Rogers had been restored to his position as medical officer of the Westminster Union, at the same time animadverting upon the tone in which that withdrawal of suspension had been couched by the Local Government Board. Last Wednesday the Council of the Poor-law Medical Officers' Association held a meeting to discuss the subject, at the close of which the following resolution was unanimously adopted:—

"That this Council cordially congratulates its Chairman, Dr. Rogers, on the removal of his suspension as surgeon to the Westminster Workhouse; but at the same time desires to record its disapproval of the tone of the communication received from the Local Government Board containing the said order, as facts do not appear to this Council to justify the strictures passed upon that gentleman. The Council further desires to express its opinion that the action of the department in writing such a letter is calculated to seriously imperil the necessary independent action of Poor-law medical officers throughout the country in the performance of their duty." It was also resolved that a copy of the above resolution should be sent to the medical journals.

THE appointment of a Professor of Pathology in the University of Cambridge will be made next May. The salary, it is stated, will be £800 a year, and the Professor will not be allowed to engage in private practice.

Medical Licensing in Germany.

DURING the year 1882-83, the number of medical diplomas conferred in the German Empire was 692, against 669 in 1881-82. In the same period 95 veterinary practitioners received diplomas, compared with 121 in 1881-82; and 22 dental diplomas were conferred, against 25 in 1881-82. There were also 315 apothecaries admitted, but the number of these has steadily declined since 1878, when it was 371.

The Pulse after Hanging.

In the Journal of the American Medical Association of December 8th appears a letter from Dr. Blankenship detailing observations upon the pulse of a criminal during and after execution by hanging. After the rope was adjusted the pulse-rate was 121; immediately after the drop it fell to 54, 52, 39, 20, and to 0 in the fifth minute; but the sixth minute it rose to 70, then 73; eighth minute, 0; ninth, 34; after this no pulse was perceptible. The death was from strangulation, the neck not being dislocated. It is stated that the heart beat two or three times between the ninth and nineteenth minutes, and once during the nineteenth minute.

Cremation in Paris.

At Paris permission has been given by the Prefect of Police, on the recommendation of Dr. Brouardel, to cremate the remains of hospital subjects, provided a satisfactory apparatus be constructed in one of the Paris cemeteries. A society for the propagation of cremation is in existence in Paris, the president being M. Koechlin-Schwartz, the mayor of one of the arrondissements.

Professorial Appointments in Berlin.

THE German Cultusminister has again acted in professorial matters without first seeking the advice of the Medical Faculty of the Berlin University in naming as Professors Drs. Sonnenburg and Gluck. The former gentleman has been appointed Professor Extraordinary of the Berlin University, but the latter has not been nominated to any professorial office. Sonnenburg was formerly clinical assistant to Lücke, in Strasburg, and afterwards was appointed to the same office under Langenbeck, and undertook the conduct of the surgical policlinic, in which office he has been succeeded by Gluck.

The Dublin Medical Students' Club.

In submitting their first annual report, the committee state that the affairs of the club are in a prosperous and satisfactory condition. This club was established last year under the auspices of the heads of the profession in this city, as a place of recreation for medical students, and one in which pupils of all the Dublin schools could meet and enjoy the benefits of mutual intercourse; and the club appears to have fully attained these objects, as far as the resources at its disposal permitted. As the number of members who were at first enrolled did not warrant any very great outlay, the committee were obliged to make every step with the greatest caution, and the present temporary premises were taken, which they are glad to say are now inade-

quate for the greatly increased requirements of the club. The reading room has been kept supplied with the chief daily and weekly journals, professional and otherwise. The committee desire to direct particular attention to the brilliant success of the members of this club at the various examinations held during the year, by which it will be seen that by far the largest proportion of prizes fell to the members. The number of members during the year was 143. The treasurer's statement of accounts was presented showing a balance of £17 13s. 5½d. remaining due to the treasurer. This was principally incurred on account of furniture, and will soon be cleared off by the incoming subscriptions and profits of the club. This being the only debt, when the amount of valuable furniture acquired by the club is considered, the committee are of opinion that the monetary stability of the club is sound and satisfactory. The committee beg to state that the present rooms are entirely insufficient for the increased requirements of the club, and strongly recommend that more extensive premises be taken, if possible, more in the track of the students.

An Example for Imitation.

A MOST praiseworthy and useful decision has been arrived at by the Board of Trade of Philadelphia Druggists, to the effect that after Jan. 1st, 1884, they will refuse to keep or deal in those proprietary medicines which are sold indiscriminately to individuals engaged in other kinds of business than dealing in drugs. Should this determination be generally followed in American cities, it must sooner or later materially influence the public craving for imaginary "heal alls," since a principal part of the favour such nostrums enjoy among their illiterate and uneducated purchasers is due to the fact that they can be bought from druggists, and are thereby ostensibly stamped with some sort of expert approval. In this country, Professor Atfield notwithstanding, the spirit of trade is too strongly pronounced among chemists to admit the hope to be cherished that they will forego the important percentages reaped from the sale of worthless proprietary articles. Could they, however, but once be brought to appreciate the benefits that would follow to the community from such a sacrifice on their part, they would certainly and speedily be more than rewarded by the improved status they would obtain, as well as by the additional *bond fide* business they would enjoy in the dispensing of actual remedial agents in place of the stamp-protected rubbish now so large a part of their stock-in-trade. If "patent" medicines were to be procured only from the corn chandler, draper, and small ware dealer, 90 per cent of those who now resort to them would lose faith in their efficacy; for though they will not choose to admit it, druggists must necessarily be conscious of the fact that they encourage the employment of secret remedies by consenting to distribute them. Is the Pharmaceutical Society strong enough and courageous enough to follow in the path opened up by their brethren in Philadelphia?

It is reported that Dr. Oliver Wendell Holmes will shortly come to England on a lecturing tour.

MR. R. CLEMENT LUCAS, F.R.C.S., of Gay's Hospital, has been elected a Corresponding Member of the Société de Chirurgie of Paris.

DR. J. MARION SIMS is said to have left ready for publication a story of Revolutionary times, entitled "Lydia McKay and Colonel Tarleton."

MM. J. CHAMBRELENT and A. Moussons ("Comptes Rendus") have proved the presence of morbid bacteria in the milk of animals attacked by splenic fever.

THE quack doctor and herbalist, Wallis, to whom we recently referred, was on Saturday last committed for trial on the charge of manslaughter for having administered to Matilda Sainsbury, wife of a carman, lobelia, which, according to the medical evidence, caused her death.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 30, Bombay 26, Madras 38, Paris 23, Geneva 23, Brussels 28, Copenhagen 22, Stockholm 22, Christiania 26, St. Petersburg 32, Berlin 22, Hamburg 22, Dresden 22, Breslau 33, Munich 25, Prague 32, Buda-Pesth 26, Trieste 35, Turin 31, Venice 25, Lisbon 38, Philadelphia 21, and Baltimore 21. Returns were not received last week from nine of the usual large cities.

UNDER the heading of "A Wish Fulfilled," a contemporary states that—"A few days since, a private in the Hampshire Regiment at Gosport called upon the Almighty to strike him blind. A little while afterwards he felt drowsy, and threw himself on a bed. On trying to open his eyes he could not do so, and he is now under treatment in the Haslar Military Hospital, not having recovered his sight!"

HIS Majesty the King of the Belgians is said to be suffering so severely from swollen feet caused by chilblains, that court festivities have been postponed. By this time probably thousands of quack nostrums have been poured into the palace by enterprising proprietors, and a larger number still of offers to cure, by that large number of amateur doctors who have always had the very same complaint that everybody else has, and know how to bring it to a sudden and miraculous cure. Poor Royalty!

THE highest annual death-rates in the large towns last week from diseases of the zymotic class were—From measles, 2.1 both in Salford and Oldham; and 2.0 in Nottingham; from scarlet fever, 4.0 in Leeds, 2.1 in Sheffield, and 1.5 in Manchester; from whooping-cough, 1.3 in Nottingham, and 1.1 in Manchester; and from "fever," 1.1 in Cardiff. The 40 deaths from diphtheria included 15 in London, 6 in Leeds, 6 in Glasgow, 3 in Liverpool, 2 in Huddersfield, and 2 in Hull. Small-pox caused 7 deaths in Birmingham, 2 in London, 2 in Sunderland, and 1 in Liverpool.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

WOODILIE ASYLUM ENTERTAINMENTS.—The first of three entertainments given to the inmates of the Woodilee Lunatic Asylum, at Lenzie, during the winter months, took place on the 18th inst. To these entertainments a number of visitors are invited, and they engage along with the patients in the night's amusements. Four-fifths of the inmates of the institution—250—were present in the recreation hall on Friday night, as well as about 200 visitors. Mr. Bryce Martin, Chairman of the Asylum Committee of the Barony Board, occupied the chair, and the medical staff and others interested in the welfare of the insane were well represented. In opening the proceedings, the Chairman referred to these entertainments as being an approved means of curative recreation for the insane. Dancing was then begun, and almost everyone present took part in it before the programme was finished. Visitors and inmates alike seemed to enjoy themselves thoroughly.

GLASGOW CONVALESCENT HOME, LENZIE.—The nineteenth general meeting of the subscribers to this institution was held on the 15th inst. The Secretary read the annual report. This stated that during the year 1,450 patients had been admitted, against 1,453 in 1882. The total expenditure had been £2,077 19s. 2d., while in the former year it had been £2,085 2s. 3d. The average stay of each patient in the house had been 18½ days. Taking into account the whole cost of the establishment, the expense per patient had been £1 8s. 8d., or 1s. 6½d. per day. There had been a considerable falling off in the amount of general subscriptions, the figures being £978 19s. 6d., against £1,061 8s. in 1882, and £1,197 4s. in 1881. It was trusted that the subscriptions from the general public would be materially increased during the ensuing year. There was, however, a very gratifying increase in the subscriptions from *employés* in public works, from churches, schools, &c. The amount was no less than £332 6s. 11d. Last year it was £243 10s. 2d., and £229 19s. 6d. the year before. The Medical Officer (Dr. Whitelaw) read his report, which stated that of the 1,450 patients admitted during the year, 584 had come from the Glasgow Royal Infirmary, 279 from the Western Infirmary, and 587 from the general public.

EDINBURGH EYE INFIRMARY.—The annual general meeting of the contributors to the Edinburgh Eye Infirmary was held on the 18th inst., Mr. John Cowan, of Breslack, one of the managers, in the chair. The annual report stated that since the re-opening of the charity thirty-four years ago, 28,437 individuals had applied for advice, and of these 410 had been accommodated in the house for longer or shorter periods. During last year the applicants were 1,153, of whom there were five treated in the house. Since July, 1875, 3,538 persons had been treated for affections of the ear, of whom 702 had been seen during the past twelve months. Since the throat department had been added in November last, the number of cases of that nature treated had been steadily increasing. The finances of the institution were in a satisfactory state, and it was proposed that the institution should henceforth be called "The Eye, Ear, and Throat Infirmary of Edinburgh." Reference was also made to the loss the institution had sustained by the death of Mr. Benjamin Bell, F.R.C.S., who had been connected with it from its foundation, and a graceful reference was made to his memory and to the services of the present medical staff by the chairman. The medical officers were then re-appointed for the current year, and the meeting terminated with a vote of thanks to the chairman.

EDINBURGH SANITARY PROTECTION ASSOCIATION.—The seventh annual public meeting in connection with the Sanitary Protection Association of Edinburgh was held on the 18th inst. in the Saloon of the Royal Hotel, Edinburgh. Professor Douglas MacLagan, President of the Association, occupied the chair. The report of the Council and the balance of funds in hand were of an eminently satisfactory nature, and spoke to the excellence of its work, and the amount of good already accomplished. The chief difficulty was to get the public to understand the importance of sanitary inspection, and such an association as this was a means of diffusing the necessary information. Statistics showing how much could be done by means of inspection, what amount of work could be overtaken by each inspector, and such like, was being collected, which would in due time be laid before the President of the Local Government Board, and would prove a most important factor in impending legislation.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 12th inst., the mortality in Edinburgh was 85, and the death-rate 18 per 1,000. There were 17 deaths under one year, and 24 above 60, of which 5 were above 80 years. Diseases of the chest accounted for 35 deaths, and zymotic causes for 14, of which 2 were due to fever, 1 to diphtheria, 3 to scarlatina, and 6 to measles, the intimations of these diseases for the week being 3, 6, 48, and 212 respectively.

OUTBREAK OF TYPHOID FEVER IN ABERDEEN.—A serious outbreak of typhoid fever has occurred in the West End of Aberdeen. The first accurately-ascertained case happened on the 20th December, in a household of six, and within four days all the members of the household, with one exception, were affected. Since then nine separate families have been attacked, 16 persons in all suffering from the disease. On the 5th January two of those affected died, one being a servant girl, aged 21, resident in the household where the fever first broke out, and the other a man of 60 years of age, who succumbed to the disease after a few days' illness. It is believed that the outbreak was caused by impure milk.

POOR-LAW MEDICAL OFFICERS' SUPERANNUATION.

We learn that the Council of the Poor-law Medical Officers' Association waited on the Council of the British Medical Association on the 16th inst., for the purpose of urging assistance in their effort for legislation. The deputation proposed to make an amendment of the provisions of the Medical Officers' Superannuation Act (England), whereby it should be rendered compulsory on Boards of Guardians to grant the same in all suitable cases. The Chairman of the Council promised that the subject should be duly considered at their meeting in April, and the deputation withdrew.

THE MEDICAL BILL.

In anticipation of the introduction of this Bill—which we have authority for stating will be introduced in the early part of next Parliamentary Session—the Irish Colleges of Physicians and Surgeons have, we understand, come to a standing to confer upon its probable provisions, and possibly upon a concerted line of action, for the mutual protection of their interests. A conjoint committee has been appointed, which will meet this week, and we earnestly trust that the subject will be approached in a reasonable and conciliatory spirit, and with the conviction, which everyone who knows the feeling of Parliament must entertain, that legislation on the lines of the Bill of last session is absolutely inevitable, and that a policy of obstruction to its leading principles is entirely hopeless. The Irish Colleges are per-

fectly right to protect their own integrity within the limits of what is just and consistent with public policy, and we are quite confident that Lord Carlingford will be always willing to listen to reasonable representations; but if the contemptible course of neck-or-nothing obstruction to reform be adopted, we hope that Government will deal with the impracticables with vigour and determination, for they will deserve no other treatment.

Literary Notes and Gossip.

We are asked by Dr. Orange, President of the Medico-Psychological Association, to announce that the Association Prize Dissertations for the present year must be sent to him at Broadmoor, near Wokingham, on or before the 30th June.

A MEDICO-LEGAL journal is one of the new ventures in American journalism. It is published under the auspices of the Medico-Legal Society of New York City, an organisation composed of members of the legal and medical professions.

A NEW monthly has been started with the year by Dr. W. S. Wells, formerly Editor of the *American Quarterly Epitome of Medicine and Surgery*, under the title of *The Analectic*. The annual subscription will be two and a-half dollars, and the publishers Messrs. G. P. Putnam's Sons, of New York.

We understand that Dr. Lauder Brunton, F.R.S., is engaged upon a revised edition of Murchison's classical work on "Diseases of the Liver," for Messrs. Longmans. This same firm will, in future, publish Mr. Proctor's "Knowledge" Library of Science, instead of Messrs. Wyman and Sons.

DR. RICHARDSON, F.R.S., is engaged on a new work, —the first number reached us as we were going to press— "The Asclepiad," which he intends issuing in quarterly instalments at 2s. 6d. It will be devoted exclusively to original research and observation in the science and literature of medicine.

ONE of the most remarkable successes attained by any modern medical book is that of Dr. Fothergill's "Physiological Factor in Diagnosis." It was issued in October last, and the publishers (Messrs. Baillière, Tindall, and Cox) inform us that in less than two months an edition of 1,000 copies was disposed of.

We have received from the publisher, H. Kimpton, of 82 High Holborn, the first issue of a new book of reference, entitled *The Medical Annual and Practitioner's Index*. This work will be found a very useful addition to the study table, containing as it does a vast amount of valuable information of the kind frequently desired by medical men. It is concise, and handy in form, and deserves to obtain a remunerative success.

"BRAITHWAITE'S RETROSPECT" is now published with cut edges, an improvement which will be very generally appreciated by its many readers. This work has completed forty-four years of existence, the volume for the half-year just passed being No. lxxxviii, and it is right to add that in usefulness and completeness it well maintains its reputation as a concise and comprehensive retrospect of medicine and surgery.

A MEMOIR of the late Dr. Heaton, of Leeds, has lately been edited by Mr. Wemyss Reid (Longmans). It is the record of a man full of enthusiasm for his profession, who was foremost in promoting every kind of progress in the locality where he passed a life of great usefulness. The memoir will be found very interesting to those who had no personal acquaintance with Dr. Heaton, while to those who knew him well it will naturally have additional attractions. We highly approve of the issue of this work, and would gladly see more frequent additions to the biographical literature of the profession. Many medical heroes are well worthy of commemoration, and the lessons of their lives more ennobling than those of the "men who delight in war."

THE new volume of the Clinical Society's "Transactions" contains the papers read during the sixteenth year of its existence, and is full of interest and instruction. A new feature, introduced for the first time in this volume, is an appendix containing brief descriptions of the living specimens exhibited at the various meetings of the Society; the departure is a good one, and renders the volume additionally serviceable for reference.

AFTER an up-hill existence for five years, the publisher of the *Index Medicus* announces a heavy loss. It cannot, therefore, go on in future unless the medical societies or the Government of the United States come forward with some subsidy, as the cost of production is too great and the circulation necessarily too limited for it to pay expenses by voluntary effort. We hope something will be done to save so valuable a publication from the grave.

THE lectures delivered by Mr. Jonathan Hutchinson two years ago at the Royal College of Surgeons, on "Temperament and Idiosyncrasy," have just been published in a collected form under the title "The Pedigree of Disease." In a prefatory note, Mr. Hutchinson explains that the present issue is a reprint of the lectures as they appeared "in one of the medical journals." For the information of those who may wish to know the fact, we may add that the name of the journal referred to is the *Medical Press and Circular*.

MESSRS. CHURCHILL'S forthcoming announcements include a fourth edition of Bryant's Surgery; a fifth of Holden's Dissections; a third of Nettleship's Diseases of the Eye; a third of Roberts' Midwifery; and a third edition of Heath's Injuries and Diseases of the Jaws. The same house also announce the following new works as in the press:—Diseases of Children, by Dr. Goodhart; Physiology for Junior Students, by Dr. Gerald Yeo; Refraction of the Eye, by Mr. Hartridge; and Vol. II. of Mackenzie's Diseases of the Throat and Nose.

GREAT BRITAIN can boast of the largest and most complete library in the world. France comes next with the Bibliothèque Nationale which, according to the annual inventory just completed, contains two million five hundred thousand volumes. In the Cabinet of Manuscripts are ninety-two thousand volumes. The Print Collection numbers upwards of two million examples, kept in fourteen thousand five hundred volumes and four thousand portfolios. A special gallery is reserved for the most costly books, which number some eighty thousand.

A CONSPICUOUS feature in the rapid progress of Australia is the extraordinary growth and spread of journalism. One of the first things that follow the settlement of population in the interior is a newspaper, which in due course attracts rivals, so that every interest and every shade of opinion are soon ably represented. Sydney has four daily papers, twenty published once a week, and several monthly. A Medical Gazette, and a University Magazine, recently started, have for their special object the cultivation and furtherance of the higher branches of scientific knowledge and literary taste.

THE *Therapeutic Gazette* last year commenced a collective investigation into the subject of diphtheria, which met with considerable success, a large number of subscribers having responded to the Editor's queries. These have now appeared in a separate volume. As more than 100 medical men contributed to the work, it is not surprising that great differences of opinion appear in it. The Editor, Dr. Mulheron, concludes with a summary, in which he endeavours to discover some harmonising element. To some extent he is successful, and the whole investigation confers credit on the *Therapeutic Gazette*, which is otherwise ably conducted, and like the volume before us, published by Dr. George S. Davis, at Detroit.

SIR JOSEPH LISTER will no doubt feel as much amused as we have been with the brilliant criticism the *Louisville Medical News* passed on his recent elevation to a baronetcy. This light of American science thus comments on the occasion: "Mr. Lister, it is said, has been offered, and has accepted, a baronetcy. So much for a successful theory. Baron de Germs should be the title of the baronetcy. Listerism is no more proved to be true than is Darwinism;

and before the century ends Listerism will be discarded and wondered at." Such utter ignorance is, truly, not often exhibited by medical journals, nor is it common to meet with so willing an expression of it on the part of writers who assume the responsibility of uttering opinions. Amiable as the weakness is, however, it might, in this instance, have been controlled with more advantage than is likely to follow from its indulgence.

THE second edition of Mr. Bernard Proctor's Lectures on Medical Pharmacy will be welcomed by a considerable number of medical men and students as well as by those who limit their work to pharmacy. There are improvements and some additions, and the work is now much more easy of reference. The table of solubilities, though rather crude from a chemical point of view, as the author admits, will be found very useful to prescribers, who are often glad to know that a dose they wish to give will be soluble in a certain amount of liquid, but do not care to have a calculation to make, or even to be referred to a theoretical accessory involving decimal points.

THE facsimile prescriptions in the foregoing work will be useful to young dispensers, and Mr. Proctor's observations upon them are sound. We confess, however, they deserve severe handling. There is no excuse for a physician risking his patient's life by illegible handwriting or by folding his prescription before it is dry and thereby having the figures transformed. Yet this carelessness and haste are of constant occurrence and many prescribers are indebted to the dispensers for the safety of more than one patient. We certainly think that pharmacists have a right to complain and patients would not, if they knew the danger, suffer prescribers thus to play with their lives.

DR. EVRICH E. SATTLER has published a History of Tuberculosis (Cincinnati: Robert Clark and Co.), which cannot fail to prove interesting in spite of its brevity, for it extends from the time of Sylvius to the present day. It contains seven chapters, the first five of which are a condensed, free translation of Spina's "Studien über Tuberculose," which has lately appeared. The views of this able opponent of Koch have already been stated in our columns. In the sixth and seventh chapters, Dr. Sattler gives an account of the investigations of Koch and subsequent experimenters, including Spina's latest labours. The book is a full review of the most important essays on the subject.

MESSRS. CASSELL, PETTER, & GALPIN have this week commenced a re-issue, in monthly parts, of their well-known "Encyclopædic Dictionary," in which, among other novelties, obsolete words are re-introduced with their original spellings and significations, so as to afford readers of old English literature a key to their etymology and the process by which modern substitutes and meanings have come about. The size of the work is quarto, and the first number to hand is an excellent specimen of typography. Assuming future parts to be equal, the completed work will form the most perfect and exhaustive dictionary of modern times, although in monthly parts of sixty-four pages, it will be years in progress.

THE fourth volume of the International Encyclopedia of Surgery, just issued, is another instance, if such were wanting, of the utter impossibility of bringing out a work, wherein a number of authors are engaged, at a definite time. Three years ago this work was announced for publication in six volumes quarterly. Twice that time has elapsed, and Volume IV has but just put in an appearance. We sympathise with the publishers and subscribers alike under the circumstances, and hope that succeeding volumes will come out more promptly. The contributors to this volume are—Drs. Ashurst, jun., G. E. Fenwick, Lidell, and Packard; and Messrs. Barwell, Butlin, and Treves.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, December 5th:—A Manual of Psychological Medicine, by E. C. Mann, M.D. Transactions of the Clinical Society of London, Vol. XVI. Transactions of the Pathological Society of London, Vol. XXXIV. Annals of Cholera, by John Macpherson, M.D. The Evolution of Morbid Germs, by K. W. Millican, B.A. Cantab. Intestinal Obstruction and Abdominal Hernia, by H. O. Thomas, M.R.C.S., and

Rushton Parker, F.R.C.S. Clinical Lectures on Mental Diseases, by T. S. Clouston, M.D. How to Arrest Infectious Diseases, by E. G. Barnes, M.D. Malignant Disease of the Larynx, by H. T. Butlin, F.R.C.S. On Sterility in Woman, by J. Matthews Duncan, M.D. Coffee and Tea, by G. V. Poore, M.D. Braithwaite's Retrospect of Medicine, Vol. LXXXVIII. Diseases and Injuries of the Eye and Eyelids, by L. H. Toeswill, M.B. A Plea for the Cure of Rupture, by J. H. Warren, M.D. Rupture of the Urinary Bladder, by Walter Rivington, F.R.C.S. The Surgical Treatment of Tumours and other obscure Conditions of the Bladder, by W. Whitehead, F.R.C.S., and B. Pollard, M.D. Report of the Medical Officer of Health for Newcastle-on-Tyne. Record of Family Faculties, by Francis Galton, F.R.S. Life History Album, by the same author. Elements of Human Physiology, by Henry Power, F.R.C.S. The Extra Pharmacopoeia of Unofficial Drugs, by Messrs. Martin-dale and Westcott. Collective Investigation of Diphtheria, by J. J. Mulheron, M.D. A Strange Life, by Nemesis. The Medical Annual and Practitioner's Index, 1883-4. Statistical Report of the Health of the Navy for 1882 (Blue Book). A Handbook of Diseases of the Liver, by H. R. Ruckley, L.R.C.P. St. Thomas's Hospital Reports, Vol. XII. A Short Manual for Monthly Nurses, by C. J. Cullingworth, M.D. The Australian Medical Directory and Handbook. Sir Lyon Playfair and Sir Charles Dilke taken to Pieces, by Wm. White. The International Encyclopedia of Surgery, edited by J. Ashhurst, jun., M.D., Vol. IV.

Correspondence.

THE COLLEGES AND THE MEDICAL BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The fate of the Colleges may be decided by the use which is made of the present interval between the stranded Bill of 1883 and the new Bill of 1884, now, no doubt, on the stocks, and shortly to be launched. The Bill of last year, had it passed, would have left the Colleges high and dry, interesting as wrecks of a bygone time, but slowly settling down into the sand and mud of uselessness and poverty.

It is the fashion now to vilify the Colleges, to describe them as selfish and effete bodies, whose set object is their own aggrandisement, who have done nothing for the advancement of medical education, and whose examinations are shams. The object of these calumnies is obvious. But speaking for the Irish College of Surgeons, I appeal to the Fellows to say whether they are willing that such charges should remain uncontradicted at this particular crisis, knowing, as we do, that our College has, at great expense, and without increasing the cost of its licence, gone on for years steadily improving its examinations, both preliminary, proficient, and fellowship, and at the same time spending large sums of money on its school, its museum, and library, so that all these departments may be kept well up to modern requirements.

I believe the Fellows will find some way of protesting against charges of incompetence from anonymous writers, and at the same time of boldly and emphatically declaring that the cause of Medical Reform does not require the destruction of the Colleges, but that, on the contrary, it will be very much better for the public and for the profession to maintain the Colleges in an efficient state, and that this can be done consistently with reform by a well-devised plan of union, and at the same time by the newly-formed and renovated Medical Council really undertaking and carrying out such systematic inspection of examinations as will insure a fair standard everywhere and a simultaneous progress in each division of the Kingdom.

Let the Colleges come forward, not to embarrass the Government in their efforts, but to give it valuable help by pointing out the dangers of sweeping away old institutions which are doing the work of the profession well, and, at the same time, firmly and energetically protesting against the theories of the self-styled "party of reform" who, in the general disruption which they hope for, see themselves floating to the surface on the troubled waters.

I am, &c.,

JOHN KELLOCK BARTON;

Past President, Royal College of Surgeons, Ireland, &c.

January 19, 1884.

[We cordially endorse Dr. Barton's appeal to the Colleges

to deal with the Reform Bill in a reasonable spirit—not adopting a mulish attitude of hostility to changes which are obviously necessary, but nevertheless defending all that is good in the Collegiate systems. We coincide with every word written by our correspondent as to the grievous injustice done to some of the Colleges by the attempt to subordinate them to so-called Universities, which are, in truth, nothing but central examining bodies, and in no single respect entitled to public consideration by reason of superior educational rank. We are well aware that, taking the Irish College of Surgeons as an example, it will compare most favourably in its educational standard with certain *soi-disant* Universities, and that it far outstrips such institutions in sterling work done for the public benefit: and we believe that this observation applies equally to other Colleges, and other so-called Universities. We must, however, emphatically dissent from Dr. Barton's statement that the Medical Bill of last session would have left the Colleges "high and dry . . . settling down into . . . uselessness and poverty." There were points, undoubtedly, in the Bill which needed amendment to do justice to these Colleges, but, as a whole, we insist that the Bill preserved all that was deserving of preservation, and would have left the Irish College of Surgeons better off than it is at present.—Ed.]

Royal College of Physicians of Edinburgh. —The following is the list of candidates who obtained the licence of the Royal College of Physicians of Edinburgh last month:—

Buxton, Thomas, Tapley, Stafford.	Minter, Ernest Denman, Plymton.
Carter, Godfrey, Ilkley, Yorks.	Myles, George Thomas, Bristol.
Godde-Smith, F. Martin, Droxford.	Potter, H., Ilkston, Nottingham.
Hunter, Andrew, Castleblayney.	Prendergast, J. J., Melbourne.
Knapton, George, Southampton.	Rimell, Alfred Tom, Kensington.

Parkes Museum of Hygiene.—At a meeting of the Council held on the 8th January, Dr. G. V. Poore in the chair, the following gentlemen were duly elected members:—Sir James Paget, Bart., D.C.L., F.R.S.; H. A. Darbishire, F.R.I.B.A. On January 17th, at 8 p.m., Mr. Pridgin Teale, of Leeds, will deliver a lecture at this institution on "Economy of Coal in Private Houses." The chair will be taken by Prof. G. M. Humphry, M.D., F.R.S.

Society for Relief of Widows and Orphans of Medical Men.—A Quarterly Court of the Directors of the Society was held on Wednesday, January 9th, Mr. Charles Hawkins, V.P., in the chair. The resignations of two members were accepted, the deaths of two reported, and two new members were elected. The Treasurer informed the meeting that a Christmas present had been made to the widows and orphans in December last amounting to £307, grants to the extent of £1,241 were made to 58 widows, 5 orphans, and 3 orphans on the Copeland Fund. The expenses of the quarter were £84. One fresh application was received from a widow and a grant made.

Liverpool Medical Institution.—At the annual meeting held on Thursday, January 10th, the following officers were unanimously elected for the ensuing year:—President: Dr. Geo. Vice-Presidents: Dr. W. Macfie Campbell, Mr. Rushton Parker, Dr. J. H. Wilson, Dr. J. Wallace. Honorary Treasurer: Dr. James Barr. Honorary General Secretary: Dr. F. Pollard. Honorary Secretary of ordinary meetings: Mr. F. T. Paul. Honorary Librarian: Dr. Burton. Council: Dr. Alexander, Dr. Archer, Dr. Carter, Dr. T. Clarke, Dr. Glynn, Dr. Grimes, Dr. Imlach, Mr. McCheane, Dr. R. F. Owen, Mr. R. N. Pugh, Mr. T. Shalford Walker, Dr. Young. Microscopical Committee: Dr. Alexander, Dr. Braidwood, Dr. Briggs, Dr. Glynn, Dr. Grossman, Dr. Hicks, Dr. McClelland, Mr. Newton, Mr. Rushton Parker, Mr. F. S. Paul, Dr. Rich, Dr. Whitford, Dr. W. Williams.

Royal College of Surgeons of England.—Two hundred and eleven candidates were admitted to the primary examination in anatomy and physiology, at the recent meetings of the Board of Examiners, of whom 133 were successful, and 78 were referred to their further anatomical and physiological studies, 65 for three, and 13 for six months. The annual course of lectures at the College of Surgeons will be commenced on Monday, February 4th, by Professor Parker, F.R.S.

Notices to Correspondents.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

R. G. L.—No appointment has yet been made to the vacant post, the filling of which is made dependent on resignation of the duties usually performed by the junior officer by the gentleman now in office as senior. The circumstances to which you allude have not been made public, and for this reason we do not consider it would be right to pass any comments on them.

TENDO.—You can do a great deal to assist the progress of sanitation by enforcing the necessity for it in your own district and among your neighbours. The scheme of lectures you allude to is deserving of all encouragement, and any assistance we can lend to the movement will be readily given.

MR. FRANCIS SMITH must apply to the Dean of the School in question, who is certainly able to afford the desired information. Whether he will consent to do so, however, will probably depend on the reasons given for the application.

MR. TRAVERS.—Prognosis is usually unfavourable in amputations of expediency. The case you mention would come under this category.

DR. FRASER.—We have so often declared the contrary that your inquiry gives us a shock of surprise.

MR. PRICE.—There is no law to prevent a parent making any disposition of his dead that is not opposed to decency and good feeling.

EDUCATION AND BODY-GROWTH.

DR. CHARLES ROBERTS, whose Report of the Anthropometric Committee attracted so much attention at the last meeting of the British Association for the Advancement of Science, has drawn up a special chart to be used in schools and families, for tracing the body-growth of boys and girls. On the chart are marked in ascending curves the average development of Englishmen, based on the measurements of over 55,000 individuals, so that any departure from normal type may be at once detected. The article which accompanies this chart (published as a supplement to the *Journal of Education*) contains some curious and interesting facts. Thus it appears that between the ages of 11½ and 14½ girls are actually taller, and between 12½ and 15½ are heavier than boys of the same age. The difference between classes is not less marked. The public-school boy at 14 averages nearly 7 inches more in height than the industrial-school boy at a corresponding age. Again, the prize-winners in life are found to have a decided advantage in height. Fellows of the Royal Society are more than 2 inches above the average stature. Dr. Roberts's practical deductions from these and other statistics deserve the attention of all parents and schoolmasters.

MR. WRIGHTSON.—The address has been printed with a special view to exciting a discussion on its subject. We do not regard the views you entertain as being especially such as have been insinuated by the writers you name. No theory can be accounted sufficient which fails to explain the principal facts experienced.

DR. CRAMMER.—We have heard of the circumstances, and always in connection with the same case. There is no hindrance to a full explanation of the arrangements which have been entered into. The letter has been sent.

THE LARYNX: THE ACTION OF THE FALSE VOCAL CORDS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—"Investigator," in your last issue, approaches his subject with a true scientific spirit. My voice was completely changed by Cataneo's training. If anyone, unselfishly desiring truth for its own end, would like to examine it, he can do so next time I visit town, on making an appointment.

Edgbaston, Jan. 19th, 1884. Yours truly, CHARLES LUNN.

A. R. F.—The custom of weighing new-born children is, unfortunately, very generally neglected in this country, and thus much useful and valuable information is lost, by aid of which many important observations might be made, leading to good results. Your idea is a good one, and worthy of being still further elaborated.

J. J. (Armoey) asks.—1. A person holding the L.R.C.S.I., in going up for the L.A.H., will he be examined in medicine and materia medica?—Yes, but not in surgery, anatomy, or physiology. 2. Would Garrod's text-book on *Materia Medica* be sufficient for a pass?—Yes. 3. Is there a clinical examination in medicine in one of the Dublin hospitals?—Yes. 4. How often do the examinations take place, and when is the first?—Examination commences on the first Monday in January, April, July, and October, and a special examination can be had for special reasons on application to the Court of Directors.—Ed.

LIABILITY OF A DEAD MAN'S CHILDREN.

A CURIOUS case is reported by telegram from Moscow, in which an action has been brought against the children of the ex-treasurer of the Melnitsky Foundling Hospital, at Moscow, to recover from them the sum of 807,500 roubles, which, it is alleged, their father had embezzled from the funds of the institution. The jury gave a verdict in favour of the defendants, and the Public Prosecutor has now lodged an appeal to the Senate against their finding.

MR. WESTCOTT.—The book referred to is of American origin. We, however, do not know the price, but this could easily be obtained on application to one of the representative houses in London.

DR. PERRY.—Resorcin is recommended as a substitute for carbolic acid in cases where the latter is employed for external application, and excellent results are claimed from its use. It is distinctly and efficiently antiseptic in properties. Eucalyptus oil, also, is serviceable.

Meetings of the Societies.

WEDNESDAY, JANUARY 23RD.

HUNTERIAN SOCIETY.—At 8 p.m., Mr. T. Mark Howell, On Laryngeal Web following Syphilitic Ulceration.—The President (Mr. W. Rivington), On Two Cases of large Calculi treated by Lithotomy.—Mr. Poland, On a Case of Ruptured Intestine.

FRIDAY, JANUARY 25TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Mr. Rivington—1. On an Unusual Form of Dislocation of the Hip; 2. On a Wound of External Carotid by a Stab in the Parotid Region, Recurrent Hemorrhage, Temporary Ligature of Carotid Trunk, combined with Ligature of the External Carotid at the Seat of Injury.—Dr. Donald Hood, On Angina Pectoris immediately followed by Pericarditis.—Dr. de Havilland Hall, On Empyema followed by Abscess of the Brain.

SATURDAY, JANUARY 26TH.

ROYAL INSTITUTION.—At 3 p.m., Professor Morley, On Life and Literature under Charles I.

FRIDAY, FEBRUARY 1ST.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At 8 p.m., Dr. Savill, On the Value of Statistics in the Study of Disease.—Dr. J. Allen Owles, Notes of the Progress and End of a Case of Aphasia.

Vacancies.

Ardee Union, Dunleer Dispensary District.—Medical Officer. Salary, £120, and £25 as Medical Officer of Health. Election, Feb. 4.
Brecon Infirmary.—Resident House Surgeon. Salary, £120, with apartments, &c. Applications to the Secretary on or before Jan. 31st.
Derbyshire General Infirmary.—House Surgeon. Salary, £100, with board, &c. Applications to the Secretary by January 25.
Sussex County Hospital.—Physician and Assistant Physician (Honorary). Applications to the Secretary by February 6.
West Herts Infirmary, Hemel Hempstead.—House Surgeon and Dispenser. Salary, £100, with board, &c. Applications to the Secretary by February 6.
Wolverhampton and Staffordshire General Hospital, Wolverhampton.—House Physician. Salary, £100, with board, &c. Applications to the Chairman of the Medical Committee, on or before Feb. 5th.

Appointments.

CAMPBELL, C. G., L.K.Q.C.P.I., M.R.C.S., Medical Officer in the Township, Saddleworth Union.
CARR, J. A., L.R.C.S.E., L.R.C.P.E., Medical Officer and Public Vaccinator for the Kippax District of the Tadcaster Union.
HANDFIELD-JONES, M., L.K.C.P.Lond., M.R.C.S., Assistant Physician to the Chelsea Hospital for Women.
HOLMAN, R. C., M.R.C.S., Medical Officer for the South Keighley District and Workhouse, Keighley Union.
JACKSON, C., L.R.C.P.Ed., Medical Officer for the Rainton District of the Houghton-le-Spring Union.
LARDER, H., M.R.C.S., Assistant Medical Officer to the St. Marylebone Infirmary, Notting Hill.
MERCEZ, J., M.R.C.S., L.R.C.P.Lond., Resident Medical Officer to the Bath General or Mineral Water Hospital.
SCANLAN, A. DE C., M.R.C.S., House Surgeon to the Royal Westminster Ophthalmic Hospital.
SHAW, J. A., M.R.C.S., Registrar to the Victoria Hospital for Children, Queen's Road, Chelsea.

Births.

CASEY.—Jan. 10, at Pembroke Road, Dublin, the wife of P. F. Casey, M.D., of Hay, Melbourne, of a son.
GODFREY.—Jan. 16, at Devonshire Cottage, Balham, the wife of Benjamin George Godfrey, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

BAITHE—WORSLEY.—Jan. 19, at St. John's, Southall Green, Edward John Baxter, L.R.C.P., L.R.C.S., L.M., second son of Henry F. Baxter, of The Green, Southall, to Clara Elizabeth, eldest daughter of the Rev. Henry Worsley, Vicar of Ashford Bowley, Ludlow.
DU-PRE—HARDWICKE.—Jan. 17, at St. John's Church, Rotherham, Cornelius S. W. H. Du-Pre, of Highley, Shropshire, to Constance Ellen, only daughter of Junius Hardwicke, F.R.C.S., M.D., of Clifton Lodge, Rotherham.
HEAD—WRAITH.—Jan. 15, at St. Saviour's Church, Eastbourne, Percy Turner Head, L.R.C.P., &c., of Hornsey, to Louisa Augusta, younger daughter of the late John Wraith, of Canterbury.

Deaths.

HARKNESS.—Jan. 16, at her residence, Ivy House, Ore, Sussex, Ann Harriette, widow of John Samuel Harkness, M.D., aged 76.
HARLEY.—Jan. 16, at 25 Harley Street, London, W., Vernon, youngest son of Dr. George Harley, F.R.S., of quinsy, after five days' illness, aged 16.
PARSEY.—Jan. 18, at Hatton, Wm. H. Parsey, M.D., Physician-Superintendent of the County Asylum.
SHEARMAN.—Jan. 13, at Davos Platz, Switzerland, Percy Edward Shearmann, L.R.C.P.Lond., eldest son of the late Charles James Shearmann, M.D.Lond., of Rotherham, Yorks, aged 36.

A Course of Lectures

ON

THE EYE: ITS DISEASES, AND THEIR REMEDIES.

Being an Abstract of a Course of Lectures delivered in the Royal College of Surgeons in Ireland,

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
Professor of Ophthalmic and Aural Surgery in the College;
Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 65.)

Atrophy of the Conjunctiva and Xerosis.

I SPOKE in my last lecture of the atrophy of conjunctiva and loss of its secretory function, which is the result of the long continuance of the third or neoplastic form of granular conjunctiva. This condition of the conjunctiva is marked, on eversion of the lid, by its presenting in patches (usually close to the lid border) a smooth, shining, white cicatricial appearance, just as if the caustics had been overdone and had burned the conjunctiva. This is the condition known as *Xerosis*, and the state of chronic irritation in which the general conjunctival and corneal surfaces remain is called *Xerophthalmia*. In this condition, which is extremely common amongst the lower classes throughout Ireland, the lid conjunctiva is totally destroyed, and its lubricating function as a mucous membrane lost, and the eye consequently suffers from attrition with the dry and hardened lid surface. On everting the lid we find it abnormally pale and glistening with streaks or patches of a cicatricial appearance on its surface. It has, indeed, so much of the tendinous appearance of a scar that it is not to be distinguished from the result of the over-use of escharotics in the treatment of the granulations. This shrinkage of the membrane extinguishes its secretory function and bends the tarsal cartilage, so that, seen from the outside, the lid is distinctly bowed and narrowed, and if, as is usual, the

lashes are not inverted, at least the hardened margin of the lid is pressed on the eyeball and creates much irritation. Entropion is a very common result, and trichiasis still more usual, the eye eventually presenting the appearance depicted in the illustration. In the worst cases of

Fig. 10.

xerosis the ocular conjunctiva is completely dried, so that it wrinkles when the eyeball is moved, and the cornea becomes quite opaque, while the epithelial scales stick to it and accumulate in the canthi. At the same time, the conjunctiva becomes nearly dead to sensation, and the excretion of the lachrymal gland suspended, so that the normal folds of the conjunctiva are obliterated, and the surface of the eye is converted into a rough, epithelial condition.

As I have said, no treatment of xerosis is of any avail, the disease being incurable. Its discomforts may be relieved to a certain extent by the constant use of emollients and lubricants—olive oil and pure glycerine are best, the latter being especially useful because of its retaining water and keeping the conjunctiva and cornea moist. Milk is also highly recommended by Von Græfe.

Treatment of Conjunctival Injuries.—The treatment in case of injury of the conjunctiva is firstly to remove the intruding substance, and then to mollify the injured surface and abate inflammation and guard against adhesions in the process of healing. I have already described the method of removal of foreign bodies.

To clear the eye of sand or such like bodies, the work-

men use two simple methods, which may be found effective at the moment of the occurrence. They introduce the point of the tongue under the lid, and lick away anything which it will detach, and, if this fails, they fill the mouth with water, and having opened the eyelids as widely as possible, squirt it with force against the eyeball. When the case is seen by the surgeon, the lid must be everted, and every speck of the lime or other foreign body picked off it and the eyeball, and, this being done, the injured surface should, in lime-burns, be touched over with a little very dilute acetic acid, to dissolve any minute crystals which remain, the acid being washed off after a few moments; and in burns by acid the same course must be adopted with strong solution of carbonate of soda.

Injury of the Eye by Lime.

This form of injury is common amongst bricklayer's labourers, in consequence of the ebullitions which take place in the slaking of lime, and which are sometimes strong enough to splash the lime into the eye. However happening, the injury is very dangerous, and the more so because the effect of the caustic alkali is rapid, and the patient is seldom seen until much mischief is done. The first effect of pure lime is to disintegrate or burn the entire conjunctiva wherever it lodges, and to destroy the corneal surface in the same way. The less slaking the lime has undergone the more injury it does, and when it is fresh and unslaked the mischief is increased by the slaking of it by the tears, so that it burns deeply. If the lime is in the form of mortar or plaster, it is less hurtful, especially if it has been long exposed to the air; but in any case, it is liable to cause serious injury. If it only lodges in spots, those parts of the conjunctiva will suffer and the remainder escape, because the lime being insoluble, does not spread to any serious extent, and, moreover, the process of slaking absorbs all the tear-water, and the deposit is, therefore, not washed away. The destruction of the cornea is the worst part of the injury, and commonly, even when the lime is in the form of mortar, the epithelium is removed from the entire cornea, which then appears as a dull opal-coloured surface surrounded by the swollen conjunctiva, and appearing as if buried in a pit in the surrounding vascular tissue. Vision is almost *nil*, the pain violent, but of a smarting rather than an aching character, and the flow of tears excessive. If the conjunctiva be burned off only in patches these places will appear as shallow depressions usually with the cake of lime adherent to their bottom. The effect upon the conjunctiva is usually the formation of large contracted cicatrices, which pucker the membrane and restrict the free movements of the eyeball, and where the lid conjunctiva is also burned there is much danger of the formation of *symblephara*, or adhesions between lid and eyeball. The effect upon the cornea is the establishment of a keratitis, which will be referred to under the head of "Injuries of the Cornea."

Treatment of Lime Burns.—The first indication is to remove the lime very thoroughly, which, in consequence of the closeness of its adhesion, is a troublesome and painful proceeding. The eyelids should be fully everted, all that can be removed by a camel-hair brush taken off, and all that cannot, picked away by forceps, or even dug out, if necessary, with the needle or Walton's gouge. The deepest part of the retrotarsal fold often contains a quantity of the lime, which may be overlooked if not searched for. When the large portions are removed, the surface should be syringed with weak vinegar and water, which will form with the remaining small particles an innocuous acetate of lime. The removal of the lime having been completely effected, a drop of atropine should be instilled, and then a couple of drops of fine oil or sweet glycerine, and the lids closed. Astringents, such as weak nitrate of silver solution and sulphate of zinc are sometimes recommended, but I have found them very irritating in such cases, and worse than useless. Acetate of lead lotions must be specially avoided, as they will deposit a coating

of insoluble chloride and albuminate of lead in the ulcerated surface, which will heal in and remain as a permanent stain. According to the extent of the injury, the subsequent treatment must be directed to allay inflammation. Cooling lotions externally will be suitable in slight cases; those more severe will require leeching to the temple, and poulticing; but, while every means is adopted to protect the injured cornea from rubbing, special care must be taken to open the eye once or twice daily, and wash out the conjunctival sac with weak carbolic lotion, lest the burned surfaces of lid and eyeball may form permanent adhesions.

Injury of Conjunctiva by Gunpowder.

The explosion of gunpowder close to the eye, as in the bursting of a gun, or from the discharge of fireworks, frequently not only burns the eye by the heat of the discharge, but drives the minute particles of charcoal into the conjunctiva, where, if not immediately picked out, they become, embedded leaving a number of black points permanently as a disfigurement. Occasionally the impact of the charcoal granules is so great that they penetrate the eye and lodge in the vitreous. The removal of them from the conjunctiva is tedious, painful, and not without danger; but it must be thoroughly done, grain by grain, to save the patient from permanent disfigurement.

Treatment of Conjunctival Injuries in General.—The after-treatment of these cases must be to mollify the injured surface—deplete the patient if the injury is a bad one, and try to prevent adhesion between the denuded surfaces in process of healing. In case of small conjunctival abrasions, I content myself usually with an evaporating lotion, complete rest, and a moderate purgative. If the lesion is larger, olive oil should be dropped in, and, if there be much ciliary irritation or aching pain, a couple of leeches should be applied to the temple, and a hot poppy stupe with bandage. In the case of burns from chemicals or lime, an ointment of vaseline with a minute quantity of atropine rubbed up in it should be daubed between the lids three or four times daily. When the surface is healing the lids should be carefully separated from the eyeball, and the eye syringed with an antiseptic lotion before each application of the ointment. Even with this precaution it will be difficult to prevent the abraded surfaces from adhering to each other.

Silver Stain of Conjunctiva. There is one other conjunctival stain which should be noted, lest an error of diagnosis may be made. The prolonged application of nitrate of silver drops to the eye is liable to produce an olive-green stain to the entire conjunctiva, which, though not materially detrimental to vision, is a great disfigurement. This staining will not take place unless the application of the silver nitrate is continued for months; and, to guard against it, it will be well, when prescribing a nitrate of silver collyrium, to direct the patient not to continue its use beyond a few weeks; but it is better, in case of ignorant or negligent patients, to avoid the risk by refraining from prescribing nitrate of silver collyrium, for which another astringent can be readily substituted. The stain is permanent, and cannot be cured.

Atropine and Eserine. Before leaving the treatment of conjunctivitis I have to refer to the use of these agents in the treatment of that disease and of corneal ulcerations. Atropine has been in fashion for some years for the treatment of almost all eye diseases, from the simplest scrofulous ulcer to the most destructive inflammations of the eyeball, the theory of its use in such cases being that it acted as a sedative to the ultimate nerve filaments, and thus was a remedy for photophobia, and that it relaxed the ciliary muscle, and thus relieved the eye of ciliary spasm and posterior tension.

In the limited number of cases in which this latter purpose was aimed at, atropine is undoubtedly useful; in the minor affections, such as phlyctenular ulceration, it

has, I believe, been proved to be of little value, and will shortly cease to be advocated by any one. Its physiological action, as we all know, is to dilate the pupil, and Dr. Harley explains this by presuming that it stimulates the sympathetic nerves which supply the radiating fibres of the iris. But the more usual view is that it paralyzes, in the case of the iris, the third nerve supplying the lenticular ganglion. We have no sufficient physiological warrant for placing confidence in its use in conjunctival and corneal diseases in which ciliary relaxation is not specially indicated. To these doubts as to the efficacy of atropine, Professor Jaeger, of Vienna, gives the authority of his great name by the following recent pronouncement:—

"Only when very violent inflammation of the cornea is present, is there any sense in the use of atropia. Atropia is used far too frequently. If a patient suffering from any eye affection comes to a physician, and he does not know what to prescribe, atropia, belladonna, and mercurial ointment are always at hand. Such physicians believe that they have in atropia, calomel, and mercurial ointment, medicines that are serviceable in all eye diseases, just as in former times everyone resorted to bleeding in general disease, gave purgatives, or otherwise acted according to rule of thumb."

With the change of fashion which periodically seizes upon ophthalmologists, Eserine, the alkaloid of the calabar bean, is now the rage, and bids fair to take the rank heretofore occupied by atropia as the universal panacea. The physiological action of this drug, as has been shown by Frazer, is to destroy reflex action, and in this way it is supposed to paralyse the radiating fibres of the iris and allow the sphincter to produce contractions. A drop of a solution of gr. ij. of eserine sulphate in an ounce of distilled water causes marked contraction of the pupil.

I believe, not only upon physiological grounds, but from experience, that eserine is far more worthy of confidence than atropine, and that it is an indispensable addition to ophthalmic therapeutics because of its faculty of suspending the reflex irritation from corneal ulcers and herniæ iridis; but to speak of it, as some authors do, as the sovereign remedy of conjunctival, corneal, and iritic diseases, is calculated to make the writers ridiculous and to cause disappointment to the practitioner from its use.

Jequirity. This, the newest addition to ophthalmic therapeutics, has been recently introduced by M. De Wecker, of Paris, as a remedy for pannus and chronic conjunctival disease. It is an infusion of the seeds of the *Abrus precatorius*, a Brazilian plant, and it acts by establishing in the conjunctiva to which it is applied a specific and comparatively transient inflammation which is expected, so to speak, to oust the old inflammation and restore the transparency of the cornea.

The idea of establishing a specific inflammation for this purpose is not new, it having been the habit many years ago to inoculate chronic conjunctival cases with gonorrhœal pus. That practice was abandoned, it being found that as a rule the remedy was much worse than the disease; but as the jequiritic ophthalmia is of a much milder character, and is capable of being limited in violence by limiting the original inoculation, it is quite possible that M. De Wecker's suggestion may prove valuable. The following is the formula for preparing the infusion according to De Wecker: Take 32 seeds (about 3.25 grammes), bruise them to a fine powder, add about 500 c. c. of distilled water; after allowing to macerate twenty-four hours add the same quantity of hot water, and after cooling, filter, when the infusion is ready for use. My own experience is, so far, negative; for though I have undoubted successes in the cure of Pannus, I am not satisfied that my proportion of satisfactory cases is greater, or the period of recovery much shorter, than with the ordinary treatment; and I do not think that the published reports of cases are conclusively in favour of the new treatment.

The jequirity acts by producing a direct germ proliferation, and the process has been carefully investigated by Sattler:—

"The cultivated bacillus," he says, "was used, some of the material was carefully applied to the conjunctival cul-de-sac by means of a disinfected brush. In the course of two or three hours slight œdema of the mucous folds, injection of all the vessels of the conjunctiva occurs; during the next hour these symptoms increased, the margins of the lid became quite red; while the mucous membrane was covered with a layer of grayish flakes, and gave off a muco-purulent secretion. If only one application has been made, these symptoms soon subside; but if the application is repeated at intervals of one to two hours for a few days, we can produce that peculiar ophthalmia to such a degree that the conjunctival cul-de-sac is covered with diphtheritic exudation material."

The latest experience of the new treatment which I have seen is from the Wills Hospital at Philadelphia, from which eight cases are reported, not one of which is stated to have resulted in a definite permanent improvement of sight; while I note that of sixteen cases reported by M. Sedan in the *Recueil d'Ophthalmologie*, only three were claimed as at all successful, the others being either not improved or admittedly the worse for the treatment.

I quote these records, not for the purpose of destroying confidence in an agent which is as yet not established by experience, but with a view to counteracting the enthusiastic laudation of the drug by authors who seem determined to be at least fashionable, if nothing more.

(To be continued.)

THE PRACTICE OF MIDWIFERY IN BYGONE TIMES IN THE CITY AND COUNTY. (a)

By G. KINLOCH H. PATERSON, M.D.,

Corresponding Fellow of the Edinburgh Obstetrical Society.

CASE 1.—Mrs. M., æt. 27 (first pregnancy); began to be ill, at full time, during the night. The pains were rather feeble at first, occurring at short intervals. However, as the following day advanced, these became more strong. About mid-day she was affected by muscular twitches and flushings of the face between or just before the coming on of a labour pain. The face at times was much flushed, along with hurried and short breathing. Being a very healthy, well formed, and stout-made woman, I thought it proper to bleed her, and took away from twelve to sixteen ounces of blood from her arm, after which she was much more quiet; the labour pains grew firmer; the os uteri dilated more and more. At three p.m. the pains having considerably increased, the head of the child—presentation natural—was pressing firmly downwards and forwards. In a short time a strong labour pain followed, during which she became convulsed; delivered her of the child. The latter was quite asphyxiated, and did not come to life again. Soon afterwards the placenta came away. Now, there was at short intervals a convulsion, followed soon by another convulsion (of an eclamptic nature). In a short time, on these becoming more violent, I cut off the hair of the head. Then it was shaved; this being done, I applied to it evaporising fluids. After this, in about three hours, leeches were put on behind the ears. Meanwhile, the convulsions continued, although at longer intervals of time; and then also, from the force of the convulsions, and from the bodily strugglings, she appeared violently maniacal—so much so that it took two, if not three, persons to keep her in bed and from hurting herself. The convulsions continued more or less up to the turn of the night, when she became more quiet, with less moaning, and seemed inclined to sleep.

(a) Part of this Paper was read before the Perthshire Medical Association on 7th December, 1883 (portions on Anæsthetics).

C

Early on the following morning I ordered a terebinthinate and castor oil injection to be given her, which operated well, and repeated it not long after. Ordered her mild, warm drinks now and then, and to be kept very quiet; also to be kindly and closely watched, and to have very careful nursing, with free ventilation of the lying-in room. Next day she seemed much relieved—her pulse felt less strong; face not so flushed. And afterwards, by attention to her bowels, food, quietness, &c., she made—though her life was all but despaired of—a very gratifying and not over long recovery.

CASE II.—Mrs. C., æt. 43, a pale, weakly-looking woman had a family previously, all grown up well. Was brought to childbed at full term. Felt labour pains near midnight, lingered on during the early morning and the coming day till afternoon, when, towards evening, her labour pains became stronger, and an individual who gave himself out as a doctor was asked to visit or attend her. He had done so, and remained some time at the poor woman's bedside afternoon and evening, and then left her, saying he would soon return, which he did, bringing some instruments with him. Not succeeding, he again left her, stating that he would return soon, but did not. At 10 p.m. I was pressing asked to visit her, without being told of the aforementioned individual's attendance. When at the bedside of Mrs. C. I found *her pains had all left her*. There she lay, pale-looking, her pulse weak, and she seemed quite worn out; her skin felt rather too cold. I immediately applied warmth about her body and to the feet; cheered her up; had hot drinks of gruel given her at short intervals. After 12 p.m. (midnight) slight labour pains began to be felt by her. On examination I found the head well down. She now seemed to be regaining more of her natural heat. I waited patiently another hour, and then, on account of there being no advance of the head, instrumentally delivered her of a living child. She did well afterwards. When out of the house and now on my return home, the *secret* was told me of the name of the previous individual who pretended to be a medical man.

CASE III.—Mrs. B., æt. 47, was ill in bed from lingering labour, late at night, in her first pregnancy, after nine months. At 11 p.m., the husband—a well to-do man, with more than usual money means, gained by his steadiness and industry—called on me to come quickly, and being willing, I started with him. Arrived at his house, and going to his wife's bedside, I found there before me an exhausted, in lying or childbed woman, aged-like, and pale and thin in her appearances. *Her labour pains had fled*. At 12 p.m. I set to work as in Case II., gave her good hopes, and patiently waited two hours, meanwhile examining her now and then. About three a.m., the pains having become more strong, and the head of the child, fortunately being small, advancing (it kept on doing so), by every additional help I could safely and cautiously think of, until I got it at length, not without difficulty, into the world—a slender, living, wee creature, indeed, having a very weak cry. I had it rolled very gently as speedily as possible in warm flannel clothes next its skin, giving it very mild, nourishing drinks, in half-teaspoonful doses, more frequently than usual, also continued applying heat outwardly to its whole body for a considerable time, while carefully attending to the necessary wants of the mother, whose spirits now were all aglow with thankfulness and joy, not only in herself, but to her own good man. Mother and child thrive, as time went on, happily well both together. Twenty years afterwards this same child (a grown up woman) I saw accidentally in her father's gig—a Scottish blooming maiden, his only child and heiress. On reflection, the thought came across my mind, if I had been at all rash at her birth, such a blooming maiden as her would likely or for certain “*nae hae been long in*” or seen “*bonnie Scotland*.”

CASE IV.—Mrs. S., æt. 49, was attended by me, and had a lengthened labour of between two and

three days. The feet and ankles of Mrs. S. were cedematous; she had the appearance of incipient jaundice, and was in the seventh or eighth month of her pregnancy. During the day and evening before the birth of the child she lay in a low, deeply-depressed state of mind; her labour pains were of a weak kind. Vomiting came on, so that nothing would stay on her stomach. The head of the child advanced very slowly. I saw her frequently before and at 10 p.m. No better. I visited her again at 12 p.m. Her friends had *her dead clothes laid out*. Used brandy and heat now as a last resource, and succeeded in delivering her at one a.m. of a still-born female child. She mended gradually afterwards, and regained her health and strength.

CASE V.—Mrs. C., æt. 23. After being several hours in labour, I succeeded in delivering her of a still-born, malformed child, the latter owing, as far as I could believe her, to *maternal impression*. A beggar woman of a very unpleasant looking appearance, some months before she lay in, had asked of her alma, which she refused. The beggar woman poured angry malice on her and her offspring, or when she would come to lie in. Well, the child she bore had its eyelids as follows—one eye shut, the other open; also one nostril closed, the other open; also hare-lip; and a club-foot. It was without a sternum; the organs of its chest inside were exposed. The patient recovered favourably.

CASE VI.—Mrs. A., æt. 21, became ill with the pains of labour at the usual time, about 10 a.m. Saw her not long after. On examination I found something quite unusual in the internal passages—two heads instead of one, and one had not the feel of the other. However, the woman was excellently healthy and well made, and the labour pains very good. I used no manual force, but helped nature gently, when the child's head soon cleared the perineum, the shoulders also. Lastly, in helping expulsion of the child's body, a darkish-like tumour made its appearance, which, on the child being completely born, turned out to be a congenital hernia, or elastic, umbilical tumour. This lying-in woman was soon well again. As to the treatment of the umbilical hernia, I had recourse to, and applied, gentle firm pressure by pads and bandages round the child's body. In the course of a fortnight or three weeks, all round the tumour—nearest the child's abdomen—sphacelated, and ere long the tumour dropped off; then I drew the opening left as well together as I could by adhesive plaster from time to time, and used afterwards half-singed cotton rags dipped in astringent lotions, and succeeded in closing the opened part. The child grew finely, and thrived well afterwards.

CASE VII.—Mrs. R., æt. 41, fell ill at nine months end, lingered all day with coming and going labour pains, until evening, when I was requested by her husband to attend her as soon as possible. On seeing her I found much more want of bodily strength than usual. On examination, the presentation was natural, but towards 7 p.m. of an autumnal evening the pains luckily grew stronger. Here I must digress for a little. Some-time previously, through one or more of the then medical journals, which informed us of the good effects of—and also as an anæsthetic—sulphuric ether it had found its way amongst us medical practising men in Perth then (in 1846). A bag with some ether in it, and flexible tube for inhaling (I having had—ere this case happened—fitted up), and on this occasion I took with me. Her labour was going on very satisfactorily, only, not so well as to herself, she looked both wearied and very much done up; then the thought flashed into my mind—Would I administer sulphuric ether through the tube between one of the pains? I did so, and, after putting the tube into her mouth I told her to breathe slowly. Then, drawing in her breath now and then for the space of five minutes, I, to have no fear, took it away, and she soon after fell into a pleasant and very sound sleep, the labour continuing, never-

theless, unaffected, and herself so like needing that state "tired Nature's sweet restorer, balmy sleep" that I thought I would try to deliver her of her child without her knowledge ere very long. I did so. A respectable aged grand dame being my only nurse, to whom I gave charge of the child, I speedily assisted her in putting on its "braw" new and clean white infant clothing. When, just as the child was set up in an upright position on its kindly nurse's knee, dressed, I observed my now mother patient in bed raise her head and shoulders and lean on her elbow, and without speaking so much as a single word to her, she looked towards the new-born child and said, "Oh, I wish my bairn was that length" (meaning born). In a moment or two I gladly convinced her that it was her own bairn she saw. On her being made to believe this, a sincere thankfulness seemed to shine through her pleasant, kindly-like countenance. Both did well.

Remarks on the Use and Advantages of a flexible Tube and properly fitted Bag for Inhaling the Vapours of Sulphuric Ether, Nitrous Oxide, Chloroform, &c., instead of a handkerchief, sponge or surgeon's lint, &c., covering mouth and nostrils:—

One of the most trying things to the operating surgeon doubtless is in his having first made himself sure—before the operation intended to be performed—as to how sound in health the patient is every way, and to be clear and confident, if it is possible, of his diagnosis. Still, that may not seem all that is to be desired. Some mishap may, and often has, occurred during or after the best-performed operations, quite unexpected; and this has been, unfortunately, experienced by the most celebrated operators, as our medical journals now and then testify. Nevertheless, I cannot help saying that I am not in favour of the usual modes through which the vapour of chloroform, &c., are inhaled by patients about to undergo operations during or at child-birth. No doubt there has been, and perhaps will always be, difficulties and perplexities unseen beforehand in certain classes of patients, as well as from the nature and present state or extent of the diseases, and also when it is remembered that the whole system of a patient may be much more fitted for an operation to be performed at a certain time than at another; even with all this there is the not unfrequent drawback to the operating surgeon: he has to begin his surgical work on living ailing patients who may have more diseases than one, and often have, or when the states of the latter's systems or strength are not in so good or hopeful condition, or may not be what it could be wished at the time to expect success.

Deeper questions, however, start up as to the responsibility of the operating surgeon himself in applying chloroform or any of the other anaesthetics. None more trying perhaps than in certain accidental injuries requiring, it may be, as soon as the case will permit of an operation, when the surgeon has speedily to decide judiciously, too, as to what is best to be done before, and during, the operation, and to perform it as skillfully as possible. If the patient's brain, heart, blood, &c., are normal, and the air of the lungs all go right under chloroform administered for the purpose of allaying pain it is well for him or her. It has been undoubtedly, and still is, a great boon and blessing to many, both male and female, before and during surgical operations.

My chief object in reference to advising the use of the tube and bag properly fitted to it for inhaling the vapour of chloroform is because it takes off much of the fear of it; and when applying it before or during the performance of a surgical operation there is not so likely to be risks, or unpleasant or painful states of the face and lips, or headache, &c., afterwards, as by the handkerchief, flannel, or sponge plan, or with surgeon's lint. Then there is also, by the use of a tube and bag, more access given to the free influence of atmospheric air while a surgical patient is under chloroform, also

more freedom to see into the mouth or air passages should anything unusual happen or take place unexpectedly.

I subjoin the following questions:—

1. How far may the operating surgeon apply with impunity, previous to, and during an, operation upon a patient, chloroform, and how much by measure may he apply?

2. In what surgical cases and in what circumstances may the operating surgeon, through his assistant, take the responsibility on himself when having as soon as possible to perform an operation?

3. Is chloroform always necessary or justifiable in surgical cases, or in what cases?

4. Can the operating surgeon be brought into trouble on account of an operation performed by him, and expenses afterwards, for not applying chloroform?

5. In reference to occasional unpleasant, or regretted "expressions" of patients (or in certain illnesses of), while any of those are under the influence of chloroform, can no mode or remedy be found to lessen or prevent their occurrence?

So much there is still to know, and attain to, if possible, that many cannot but acknowledge the truth of, and utter, the words of old more clearly and anew—

"Ah! how hard it is to climb
The rugged steep, Parnassus hill,
Where Fame's proud temple shines afar!"

Perth, N.B.

THE RADICAL CURE OF HERNIA BY THE METHOD OF DISSECTION.

By KENDAL FRANKS, M.D. Univ. Dub.,

Fellow Royal College of Surgeons; Fellow Academy of Medicine in Ireland; Surgeon to the Adelaide Hospital; Surgeon to the Dublin Throat and Ear Hospital, &c.

(Concluded from page 70).

Case II.—F. H., æt. 24, was admitted to the Adelaide Hospital in June, 1882, suffering from an oblique inguinal hernia of the right side. On June 22nd he fell off a car, and shortly afterwards felt considerable pain in the right groin and a large swelling appeared, which however, vanished when he lay down. It was about the size of a small sausage. The operation above described for the radical cure was performed on July 3rd. He was a man of intemperate habits, and when ether was administered he became so excited that it had to be discontinued, and chloroform given in its place. This excitement continued for hours after the operation was completed. In this case the internal and external rings were sutured in the usual way, the sac having been returned into the abdomen. The dressings were changed on the fourth day, when the wound seemed perfectly healthy, and the drainage tube was removed.

On the tenth day the dressings were found greatly disturbed and part of the wound exposed, owing to the fidgetty restlessness of the patient, and there was some slight purulent discharge. Three days later, as the upper wire suture protruded through the skin wound which had begun to gape, it was removed, and the second suture about a fortnight later. The healing process was not completed for several weeks. On August 15th a slight return of the hernia took place, but it was immediately returned and a pad applied. It did not again descend while he was in hospital, where he was detained by an attack of broncho-pneumonia, and when he left the hospital, on October 10th, there was no appearance of hernia, even when standing erect without a pad. He was ordered to wear a truss for one or two years. I saw him some months later. He was not wearing a truss or support of any kind, though the hernia had returned. It was not so large as when he presented himself at the hospital.

The failure in this case was due to the very great difficulty in keeping the wound aseptic throughout in a patient whom it was impossible to keep quiet in bed, and who was detected in getting stimulants conveyed to him surreptitiously. Unfortunately it is not easy to bandage a restless man to a St. Andrew's cross till healing is complete, as has been recom-

mended by Dr. Buchanan, of Glasgow, in the case of children.

Case III.—C. D., a gentleman, æt. 24, consulted me two or three years ago for an oblique inguinal hernia of the right side. At that time it was but alight, scarcely more than a bubonocoele. I advised him to wear a truss. This he did in an intermittent sort of way, generally leaving it off when he was dancing or taking other exercise. He showed himself to me again in April last, with the view of having a radical cure performed, for which he was most anxious, as he was leaving this country for America in the following August. The hernia was then found to have increased in size, though still not large, and it had descended into the scrotum. On the 1st of May last, with the assistance of Mr. Barton and Mr. J. H. Scott, I operated as in the former cases, putting in two silver wires. The wound was dressed according to Lister's method. The dressings were not disturbed till the seventh day, when the incision was found firmly united, and could scarcely be recognised. The drainage tube, a very small one, was then removed, and the dressings re-applied. Four days later the whole wound was found healed and the dressings were accordingly discontinued. A pad of salicylic wool was laid over the region and kept *in situ* by a light truss, and the patient was allowed to sit up. The next day, that is the twelfth day, he went out for a drive. The highest record of temperature, which was regularly taken, was 98° 4', and the pulse never exceeded 76. Shortly afterwards he went down to the West of Ireland, and was out shooting and boating nearly every day. I even learnt that he used to bathe in the sea without a truss. I saw him again on the 1st of August. There was not the slightest sign of a return of the hernia; there was no cough impulse; the wires could be distinctly felt, and he suffered no pain or uneasiness. He is now in America.

In none of these cases was there any trouble with the cord or testicle, beyond a passing pain of a neuralgic character, which was easily relieved. In two of the cases there was, during the first twenty-four hours, some retention of urine, but only one required a catheter to be passed and then only once.

The second method of operation which claims our attention, and which has a wider field of application than the first, is that in which the abdominal openings are sutured, preferably with silver wire, after excision of the sac. Dr. Guénod (a) thus describes the operation, which he divides into six stages:—

1. Incision of the skin and subcutaneous tissue down to the sac.
2. Dissection and isolation of the sac, performed with blunt instruments or with the fingers; if this dissection be impossible, isolate the neck of the sac, so as to be able to ligate it.
3. Incision of the sac, reduction of its contents, subsequent to division of the constriction, should the hernia be strangulated, or after resection of omentum, should this be adherent to the inside of the sac.
4. Ligature, single, double, treble, or quadruple, of the neck, carried as high up as possible, and excision of the sac.
5. Suture of the pillars, when necessary.
6. Closure of the external wound.

During the space of three years in the surgical clinic of the hospital at Bâle, forty-four operations of this kind had taken place, and of these, thirty-four had been found and examined by Dr. Guénod at different periods. Twelve had a return of the hernia, and 22 had been completely cured; these latter were divided into 8 cases of reducible hernia, 6 inguinal and 2 crural; and 14 incarcerated, 9 inguinal, and 5 crural. (b)

Most of the cases which present themselves for operation, and in which this method is applicable, that is, in all cases where it would be unwise to return the sac untouched into the abdomen, give but little trouble in carrying out these various steps. But there are cases in which considerable difficulty may arise, and to deal with which many suggestions have been offered.

The first of these are cases of congenital hernia, where the sac consists of the patent tube of peritoneum, carried down originally by the descent of the testicle, in which cases modifications in the preceding mode of operating must be made. Moreover, in cases of old scrotal hernia, the sac may

have contracted adhesions to the testicle, and the tissues of the spermatic cord may be found spread out and intimately adherent to the back of the sac in its whole length. This, no doubt, is most frequently seen in old cases of oblique inguinal hernia, but that it may also exist in cases of the direct variety is also true, as the case I shall now relate will sufficiently show.

Case IV.—M. B., æt. 50, employed in a forge, came into the Adelaide Hospital under my care on the 26th January, 1883, suffering from a large inguinal hernia of the left side. He looked weakly and sallow, but stated that previous to the descent of the hernia he had always enjoyed good health. The account he gave of his rupture was shortly as follows:—About six or seven months previously, whilst shoeing a horse, he got what he called a "draw," which caused him pain in the left groin at the time. Examining himself afterwards, he found a small lump, which he referred to the external abdominal ring. This lump gradually increased in size till it attained its present size. He also complained of pains under the ribs, which shot down to the groin. He had been affected lately with some pain and delay in passing water, which he attributed to the kick of a horse, received about three weeks ago.

On admission he presented a very large scrotal hernia, which could be easily reduced, but owing to the size of the abdominal openings, could not be kept in position. The finger passed through the external ring at once entered directly into the abdominal cavity. The opening in the conjoined tendon could be distinctly felt. The hernia was direct. These openings admitted the tips of three fingers.

After the hernia was reduced, the great thickened, baggy sac, which remained irreducible, was very noticeable. When the bowel was down the hernia measured 6½ inches longitudinal diameter and 3 inches in the transverse.

I proposed to him to do an operation for the radical cure, and he consented. Accordingly this was done on Feb. 1st last. When the sac was reached it was found impossible to isolate it completely from the spermatic cord, the constituent parts of which were spread out in a thin layer over the whole of its posterior part. Not having previously obtained the consent of the patient, it was decided not to employ castration, which, owing to the atrophied condition of the gland, I felt very inclined to do. I, therefore, endeavoured to detach the sac from the cord. This was effected completely in the neighbourhood of the ring, but lower down it became evident that part of the sac must be left behind. I then cut across the sac about half an inch below the ring. I had no fear of its retracting into the abdomen, as it was adherent to the margins of the deeper opening. I then passed two fingers of the left hand through the openings into the abdominal cavity, and with the right hand passed a strong Liston's needle armed with stout silver wire through the whole thickness of the abdominal parietes, from the aponeurosis of the external oblique to the peritoneum, till I felt the point of the needle on the tip of my finger inside the abdomen. Withdrawing the finger, with the point of the needle pressing upon it, the wire was brought into view, and caught, and the needle withdrawn. It was then passed unarmoured through all the tissues on the other side, including the peritoneum, threaded with the wire and withdrawn. Two more silver sutures were passed in the same way lower down, and when their corresponding ends were pulled together, it was found that the edges of the openings, and included between them the neck of the sac, could be well brought together. The wires were then twisted in the usual way, and the twisted ends flattened down. As much of the sac as could be dissected away from the cord was then removed, the wound closed with catgut, and a drainage tube inserted. The whole operation and after-treatment was performed antiseptically, according to Lister's method. That night all our precautions were in imminent peril of proving abortive. The nurse in charge of the ward left it for a few moments. The patient took advantage of her absence to get out of bed and go to the closet. On his return, finding I suppose, the dressings irksome, he began to remove them, and had just reached the deep dressings, when the nurse returned and discovered what he was doing. She at once sent for the resident, who proceeded without loss of time to replace the dressings, using all the precautions which the occasion allowed of. The next morning I discovered that the scrotum was swollen and fluctuating, and from its darkened colour it was evident that, owing to his perambulations of the previous night, he had got an hæmatocele.

(a) Thèse de Bâle, 1881.

(b) *Revue des Scien. Méd.* Hayem. 1882. Vol. xix., p. 662.

The evening before, when inspected, there was no sign of swelling or disturbances.

The wound was examined, and as it appeared to be doing well, it was redressed as before, and was not again disturbed till the eighth day, when it appeared uniting well. The drainage tube was removed. On the 10th it was dressed again, and also on the thirteenth day. A small piece of the skin wound at the seat of drainage was not quite healed, but in a few days later cicatrisation was complete.

The progress of the hæmatocele was not so rapid, as it began to suppurate on the seventh day, and free incisions were made into it on the eighth, the temperature on the night before being 101.2°, though previously it had not reached higher than 100.6°, on the second day, after which it had fallen. The patient now slowly but steadily improved, and he left the hospital on the 7th April without the smallest sign of a return of the hernia, and without cough impulse. I have not since been able to see him.

Two very similar cases were reported by Dr. Kraske, of Halle, on which Volkmann had operated. (a) The first was a man, æt. 42, the subject of an irreducible congenital scrotal hernia, which was very painful. He was very anxious to have an operation done, which was accordingly performed—the sac was opened, the hernia reduced. It was impossible to dissect away the sac from the parts adhering to it. Castration was performed as high up as possible, by raising the sac and cord at the same time, ligaturing both together at the neck, and then having divided them both below the ligature, the cord and testicle were removed with the tunica vaginalis. Carbolic dressings were applied over all. The patient recovered and left the hospital wearing a pad and bandage. There was no sign of a return of the hernia, even on coughing. The second case was very similar, only that the sac contained intestine and omentum, both of which were carefully replaced as high up as possible beyond the neck of the sac. This case was likewise followed by cure, coughing producing no effect at the ring.

Sometimes, however, in acquired inguinal hernia, when the sac is old, it not only adheres to the cord, but may be intimately connected with the tunica vaginalis below. If it be roughly pulled upon, the testicle may come bodily out of the scrotum, a point to which Mr. Mitchell Banks (b) has called attention. In such cases, as well as in cases of incomplete descent of the testicle, Nussbaum fastens this organ to the bottom of the scrotum with sutures, then dissects away the sac from the cord, sutures it and divides it in the usual way; but taking into consideration the usually undeveloped condition of the testis in these cases, Kraske prefers castration, a proceeding advocated also by Mr. Banks, two successful cases of which he published in 1881. Whatever may be the course pursued in the young, in the case of a man advanced in years with an atrophied or undeveloped testis, castration would undoubtedly remove many of the difficulties, and would probably aid, not only in the more rapid progress of the case, but in the greater efficiency of the cure.

In cases of congenital hernia in children the employment of castration is, of course, out of the question. Dr. Buchanan, of Glasgow, (c) has employed an expedient which proved successful in his hands, and has the advantage of preserving the organ intact. He dissects up the sac and divides it. The lower portion he turns down so as to form an artificial tunica vaginalis. The upper half he rolls up and uses it as a plug for the internal ring. He then stitches up the canal with silk. The edges of the internal ring are drawn together with silver wire, but this, instead of being allowed to remain in the wound, is removed on the tenth day. The child on which he operated thus was kept quiet by being secured to a St. Andrew's cross with bandages. At the end of four weeks it was liberated and was then perfectly cured.

Besides the difficulties which present themselves, owing to adhesions having formed in an old hernia between the outer wall of the sac and the spermatic cord, or to the sac being congenital and of old standing, other circumstances may exist which may complicate the operation, but which prove at this same time its superiority over other methods of dealing with hernia generally. Among the many instances which we find published in late years, I may cite one which was brought

before the Seventh Congress of German surgeons, by Dr. Pauly, of Posen, (a) it was the case of a woman, æt. 43, the subject of an enormous inguinal hernia of the left side, which could not be controlled by any truss. The hernia which had existed for 13 years, reached nearly to the middle of the thigh, and had at its base a circumference of nearly 15 inches. After the replacement of the tumour, the inguinal canal was found to be dilated into a ring which could easily admit four fingers; a pouch as long as the forearm, consisting of skin and hernial sac remained. Under antiseptic precautions the hernial sac was extirpated and shown at the Congress. It was capable of holding about two pints of water. The opening was closed by sutures in the usual way. The case did well, and when discharged from treatment showed no sign of relapse. Dr. Pauly urges particularly that before applying the ligature to the neck of the hernial sac the sac should be opened, otherwise, notwithstanding the apparently 'complete reduction of the hernia, a small loop of intestine might be penetrated by the needle.

I may here observe that this method of operating is known in Germany generally as Czerny's method, and Dr. S. D. Gross (b) thus refers to it: "An extension of this operation (simple suture of the rings) has, within the last few years, been practised by a number of surgeons, chiefly European, attention having been previously directed to it, in 1879, by Prof. Czerny, of Heidelberg."

Now, Czerny's first five cases were published in 1878, (c) seven years after Lister recorded his two cases in his address on Surgery, and after Marcy, of Boston, had performed the same operation in strangulated hernia, published in 1871. It is evident, therefore, that he has no claim to priority, nor is there any special reason why his name should be attached to it.

Another remarkable case in which this method was employed was reported by Prof. Lawrie, of Lahore. (d) The patient was a gentleman, æt. 34, who was the subject of a right inguinal hernia, complicated with a tumour of the right testicle, which after removal proved to be a soft carcinoma. The tumour was as large as the closed fist, and was of three months' growth. On Jan. 5th, 1883, the operation was performed. The hernial sac was found to be congenital, and contained a mass of omentum which was adherent to the upper surface of the tumour. The neck of the sac and its contents were transfixed *en masse* with double catgut, which was tied on each side immediately outside the ring. The sac, omentum, and tumour were amputated half an inch below this point, and the ring with the thick stump in the centre was occluded by means of the catgut ligature which held the stump. "The patient left Lahore on Jan. 20th, well and not wearing a truss." Prof. Laurie has operated in this manner twelve times, the results being in each equally good. "Under proper antiseptic management," he says, "without which the operation would be impossible, the wound heals at once, and consolidation of the ring is complete in from eight to ten days."

In a few cases the post-mortem appearances of the parts at varying periods after the operation have been put on record, and these all demonstrate the good results which follow from this method. In no case that I have found, where Listerian precautions were adopted, have the evidences of peritonitis, as a result of the operation been seen. In a case reported by Mr. M. Banks (e) the patient died about a fortnight after operation with symptoms referable to the nervous system, he being well advanced in loco-motor ataxy. The pillars of the ring were found "agglutinated together with lymph in such a way that the inguinal aperture was completely closed, and in the lymph the sutures were completely buried." In a second case, reported by Mr. Davies Colley, (f) in which the man died three years after operation, "the hernial ring was found represented by a slight depression on the inner side. The *processus vaginalis* was obliterated, and the tunica vaginalis was nearly obliterated.

I need not here detail cases to show that the radical cure by antiseptic suture is applicable to other kinds of hernia besides inguinal. The two cases related by way of illustration in the address on Surgery in August, 1871, by Sir Joseph Lister were, the first a case of large umbilical hernia,

the second a ventral hernia, both completely successful. It is now the only method employed to effect the radical cure of femoral hernia. An interesting case is reported in the *Lancet* for August 20, 1881, in which Mr. Wood, the author of the subcutaneous wire operation, employed it as a supplemental operation in a case of strangulated femoral hernia, and the same has been done frequently by others. These instances sufficiently show the wide application of which this operation is capable. The same cannot be said for any other method of treating hernia radically. Wood's great success in his wire operation has been attributed to the care he exercises in selecting his cases, avoiding those in which he had reason to believe that the wire operation would not be successful. In 1882 (a) he acknowledged that in cases of congenital hernia he now always removed the sac through a small opening, using antiseptic precautions, as his large experience of the subcutaneous wire operation showed him that these cases were less amenable to the radical cure than others. The same observations apply to Mr. Spanton's method with the corkscrew needle. In his list of cases, published in July, 1882 (b), he says: "The most suitable cases for cure are, I think, those occurring in the young," and his table of thirty-four cases shows that twenty-two were below the age of eleven, and the remainder between the ages of thirteen and twenty-seven. This shows at once the large number of cases excluded from the benefits which his operation might afford. If we further exclude all those forms of inguinal hernia where adhesions exist between the sac and its contents, or where the testicle has either not descended, or is adherent to the sac, the result cannot fail to convince us of the great superiority of the method by antiseptic suture. In the *British Medical Journal*, p. 1110, Dec. 8th, 1883, a new operation is described by Dr. Fitzgerald, of Melbourne, in which he obliterates the canal by means of a crucial suture, which is passed subcutaneously. "The sutures being of pure gold and perfectly unirritating, are left in permanently." This is an improvement on the method advocated by Dowell, of Texas (c), in which silver wires are introduced through the margins of the rings, and the free ends brought out at the same side of the opening in a line parallel to the inner pillar of the ring. They are secured over a piece of wood or cork, as in quilled suture, and are removed about the seventh day. Dr. Fitzgerald's method has the great advantage over other methods of subcutaneous suture in this, that the wire is not removed, but remains as a permanent barrier against the re-descent of the hernia. Ingenious as this method is, it can lay claim to no points of advantage over the antiseptic suture, or open method, or method of dissection, as it is variously styled.

I have no doubt that any surgeon who will give this method a trial, and who will perform it under the protective influence of full and unmodified Listerian principles, will hesitate before he surrenders it for any one of the methods based on the principle of blind surgery.

Clinical Records.

CASES IN PRIVATE PRACTICE.

Case of Albuminuria, Anasarca, Liver dyspnoea, Weak heart, Chronic Bronchial affection, Treatment; Recovery.

Under the care of JOHN W. MARTIN, M.D.,
Sheffield.

I WAS called in a hurry to see W. R., middle aged, a brewer's cooper, living in Napier Street, Sheffield, who had been seized suddenly about 12 o'clock midnight, with urgent dyspnoea, bordering upon apnoea. He was of medium height, stout, bull-necked, puffy looking, and of a pasty complexion, exceedingly partial to beer, and had been indulging largely during the Whitsuntide. When seen, the dyspnoea continued very urgent, there was general anasarca of the body, the legs being greatly swollen. Pulse 128, very weak, but regular. Heart's action very weak, the first sound very faint, and the second almost lost. Impulse imperceptible, no increase in the area of cardiac

dulness, nor were there any murmurs present. He had been troubled for some time with a cough attended by bronchial expectoration of tenacious clear frothy mucus. The lungs were fairly resonant, the respiration was roughened throughout; some coarse moist râles were heard all over. The tongue was dry, bared at the tip, furred at the base. The bowels had been moved. Temperature 100°. Urine scanty and on examination, acid in reaction and highly albuminous, $\frac{1}{2}$ in bulk.

I ordered mustard stupes to be applied to his feet, large mustard poultice over the heart, poultices of linseed over the loins, and prescribed the following mixture:

R. Amm. carb., 3j;
Sp. am. sromat., 3ij;
Tr. lavandulae, 3iss;
Tr. cardamomi, 3ij;
Syrup zingib., 3j;
Aque, ad 3viij.

M. 3j. every third hour.

Ordered him to have plenty of beef tea and milk.

May 21st.—Passed a restless night for two hours in the middle of the night, felt very faint and low. Better this morning, pulse 112, stronger. Heart's action improved. Passed water freely last evening, still highly albuminous. Tongue cleaner and moister, less furred towards the base. Desire for food returning. No motion from the bowels. I ordered a drachm of pulv. jalapae co. to be given at once; and changed his mixture for:—

R. Pulv. pot. nit., 3iss;
Sp. eth. nit., 3ij;
Tr. scilla, 3iss;
Tr. digitalis, 3j;
Aque chloroformi, 3viij.

M. 3j. every fourth hour.

I also wet cupped his loins, taking away about six ounces of blood.

22nd.—Much better generally. Pulse 84. Tongue clean. Temperature 99.2. Appetite improved. Heart's action stronger. Anasarca diminished. Bowels had been three times freely moved; motions loose and watery. The urine scanty. Through a misconception, the poultices to the loins had been omitted; ordered them to be reapplied.

23rd.—Much improved. Tongue clean. Pulse 80, firm and regular. Temperature 98.4° (normal). Passing water freely, of a good colour, and containing only about one-third albumen. The anasarca disappearing, traces alone remaining. The heart's action much stronger, both sounds strong and distinct. Has a good appetite, and in every way is more comfortable and in better spirits. Treatment continued.

24th.—Improvement continues. Urine abundant, but showed $\frac{1}{2}$ albumen to-day. No motion. Repeated the 3j. of compound powder of jalap, and altered the medicine to:—

R. Ferr. amm. cit., 3iss;
Tr. scilla, 3ij;
Tr. digitalis, 3iss;
Potass bicarb., 3iss;
Aque chloroformi, ad 3viij.

M. 3j. every fourth hour.

25th.—Up and dressed. Tongue clean, moist, and firm. Pulse 80. Temperature normal. All traces of anasarca gone. Passing an abundance of urine; had four liquid motions. Treatment continued.

28th.—Improvement in every respect. Urine abundant, and presents a mere opalescence on application of the heat and nitric acid tests. Treatment continued. The subsequent course of the case was most satisfactory; on the 31st there was a relapse as regards the amount of albumen passed, one-third being found on applying the test, but this soon passed off again. Anasarca had quite disappeared, and only the faintest trace of albumen was to be noticed shortly before he passed from under my observation, through a change of residence from Sheffield to Burton-on-Trent.

It has been decided to drain the Great Ormond Street Hospital for Children on modern scientific principles, under Mr. Rogers Field's advice and superintendence. £1,500 will be required to carry out the necessary works, which will be undertaken forthwith.

Special Articles.

THE IRISH POOR-LAW SUPERANNUATION BILL.

THE future of this measure was the subject of a private deputation to the Chief Secretary for Ireland on Thursday last, convened by the Irish Medical Association. The Irish College of Physicians was represented by its President, Dr. Moore; its Registrar, Dr. J. W. Moore; and by several of its Fellows. The College of Surgeons was represented by Drs. Barton and Hamilton, the President being absent in consequence of indisposition. Dr. Banks attended as President of the Dublin Branch of the British Medical Association, and Dr. Duffey as its Secretary. The Irish Medical Association was present in the persons of its President, Dr. Jacob; its Chairman of Council, Dr. Thomson; its Hon. Sec., Dr. Chapman; as well as Drs. Purcell, Browne, Taggart, &c. The deputation was introduced by Dr. Lyons, M.P., Mr. Brooks, M.P., and Mr. Meldon, M.P.; letters being read from Mr. Gibson, M.P., and Col. King-Harman, expressing their strong approval of the Bill.

Dr. Jacob submitted to the Chief Secretary the necessity for the Irish Government giving to the Bill its most active support in the coming session, pointing out that it had failed to pass in the two last sessions only because of the late period at which it had been brought forward; that it had the united support of almost all parties in the House of Commons, and of the Department officially interested in the question; that it has been investigated by a Select Committee of the House and approved in its present shape; and that the Government had for two successive years pledged itself to its adoption. Dr. Jacob reminded the Chief Secretary that a most forcible memorial to the same effect had been presented by the non-medical union officers, whose views were entirely in accord with those of the deputation, and he finally urged that the Irish Government should, in the coming session, take the matter seriously in hand and pass the Bill.

The Chief Secretary was afterwards addressed by the President of the Colleges of Physicians and Surgeons and of the British Medical Association branch, as well as by the Members of Parliament.

In reply to the arguments urged, the Chief Secretary said that there were already two measures which the Irish Government was pledged to bring forward before all others, and that he was not prepared to pledge himself as to the measure which should follow these. But he regarded the Superannuation Bill as one of the most important of the Irish Bills, and he would certainly give it his earnest support. He thought it should remain in the hands of Mr. Herbert Gladstone, and that, whenever the Bill came under discussion in the House, he would give all the support of the Irish Government as well as his own personal aid.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 25TH, 1884.

Sir ANDREW CLARK, Bart., M.D., F.R.C.P., President, in the chair.

Mr. WALTER RIVINGTON on

AN UNUSUAL FORM OF DISLOCATION OF THE HIP.

On August 5th, 1883, a man, *et.* 34, was standing with his legs apart and his body bent forwards when some large packing cases fell upon him, striking him on the right side of the head and right hip. The head of the right femur was

displaced from the acetabulum. The symptoms were complete immobility of the thigh, which was slightly flexed; abduction and commencing inversion of the whole limb, and shortening to the extent of 3-8ths of an inch. Under ether it was readily reduced on the first employment of manipulation, the head entering the acetabulum with a click, and with slight grating. The dislocation differed from the ordinary sciatic form in the abduction, slight inversion, and less amount of shortening; and it did not resemble some published instances of anomalous displacements. It might best be described, perhaps, as the first stage of a sciatic displacement. On September 11, the patient, being able to walk, left the hospital cured.

Mr. WALTER RIVINGTON on a case of

WOUND OF EXTERNAL CAROTID BY A STAB IN THE PAROTID REGION; RECURRENT ATTACKS OF HÆMORRHAGE; TEMPORARY LIGATURE OF THE CAROTID TRUNK, COMBINED WITH LIGATURE OF THE EXTERNAL CAROTID AT THE SEAT OF INJURY.

The patient, a carman, *et.* 31, was stabbed by his wife in the left parotid region on December 24th, 1882. Hæmorrhage had ceased before his admission into the London Hospital, and his wounds were brought together by sutures. On December 30th and 31st some hæmorrhage occurred, but it was readily arrested by pressure. Swelling of the left side of the face and erysipelas supervened, necessitating incision and the insertion of drainage tubes. He went on well till Monday the 15th of January, 1883, when severe hæmorrhage occurred, arrested by pressure with a sponge and bandage. On the following morning he was seen by Mr. Rivington. On removing the bandage and compress blood gushed out in a strong jet from a wound over the position of the external carotid behind the jaw. Pressure stopped the hæmorrhage. To avoid loss of blood during the process of securing the wounded vessel Mr. Rivington cut down upon the carotid above the ordinary seat of bifurcation of the common carotid, and passing a cat-gut ligature round one of the carotid trunks (either the common or external carotid) tied it so as to stop the current without dividing the coats of the vessel. On removing the pressure from the wounded external carotid only a languid stream issued, and the vessel was tied above and below the opening. The ligature round the main trunk was then untied, but left under the vessel and the wound was closed, the ends of the ligature passing out between its lips. No more hæmorrhage occurred, and the patient made a good recovery. The cat-gut ligature dissolved and came away from under the main trunk spontaneously on the sixth day after operation.

Dr. COUPLAND observed that a very similar case had been reported in a former volume of the Society's Transactions, and that the patient was present in the ante-room for examination.

Dr. DONALD HOOD on a case of

ANGINA PECTORIS IN WHICH THE ANGINOUS SYMPTOMS WERE RAPIDLY FOLLOWED BY PERICARDIAL EFFUSION.

The history of the case was briefly as follows:—A gentleman, *et.* 65, resting on a sofa, apparently asleep, was suddenly roused by the window curtains being on fire. He quickly jumped up to extinguish the flames, and within half an hour of this exertion he was suddenly seized with severe heart cramp. Seen shortly afterwards by Dr. Hood he was noticed as being blanched, barely able to speak, heart irregular and fluttering, pulse of peculiarly low tension, with agonising cramp-like pain over cardiac region. Hot stimulating applications, brandy, ether, and opium, were used freely, and the patient slowly lost the pain, and a general improvement of the circulation took place. Twenty-four hours after the commencement of the attack a soft pericardial shuffle was noticed, within a few hours it had deepened into a distinct rub. From this time during the succeeding ten days the case assumed all the characters of one of pericardial effusion, the amount of fluid being but moderate, and apparently completely absorbed within the ten days. A fortnight later the patient was found to have a systolic apex murmur and symptoms of incompetency of the mitral valve rapidly developed. The patient died four months later from syncope, and at the time of death was the subject of cardiac dropsy. No post-mortem could be obtained. Dr. Hood suggested as a possible explanation of the primary attack with its subsequent train of symptoms that the patient was the subject of some fibroid degeneration of the heart. Roused from sleep by the flames, his alarm and exertions caused a sudden distension of the heart cavities which possibly gave rise to some lesion of the

visceral layer of pericardium and so started the pericarditis. In support of this hypothesis Dr. Hood called attention to the series of cases of fibroid disease of the heart, collected and published by the late Dr. Fagge in the 25th volume of the *Transactions of the Pathological Society*, and stated that in more than half of these cases the patients were found to have been the subjects of pericarditis. He further suggested that fibroid degeneration of the heart should be looked upon as a possible factor in those cases of pericardial effusion in which it was difficult to explain the cause of the pericarditis.

Dr. BURNLEY YEO asked if the patient had shown any signs of renal changes, or of arterial degeneration?

Dr. DE HAVILLAND HALL narrated the history of a patient who, soon after quarrelling with his son, was seized with pain in the præcordium, and when seen by Dr. Hall the spasm was of a severe character, accompanied with frequent and feeble pulse; there was no murmur audible, and the temperature was not raised. The case clearly looked like angina, and Dr. Hall prescribed diffusible stimulants, with a subcutaneous injection of morphia. Two days later the patient was visited again, when it was asserted that, though better on the intervening day, pain was still experienced. At this time friction sounds were heard over the heart, and death occurred five days afterwards. Dr. Hall considered that this case was plainly one of angina succeeded by pericarditis forty-eight hours after the attack.

Dr. GLOVER asked if Dr. Hall had noticed any elevation of temperature in the later stages of his case; and, in reply,

Dr. HALL said the highest recorded figure was 99° or 100°.

Sir ANDREW CLARK expressed curiosity to learn why Dr. Hood had not resorted to nitro-glycerine as a remedy in the treatment of his case. He also desired to know what degree of temperature had been reached in it, and in connection with this question drew attention to the fact that many cases of pericarditis go through their course without any exaltation in this respect.

Dr. DUCKWORTH suggested that pericarditis might pass unrecognised under the description of angina pectoris. He had seen no cases in which the former succeeded on the latter, but he recognised the existence of a pseudo-angina, especially when disease of the aortic valves existed, and thought Dr. Hood's case might possibly be of such a nature. Few physicians had seen fatal cases of angina, and for each such there were many in which the pain did not terminate in death, being of the character of an acute temporary neuralgia.

Dr. ANGEL MONEY asked how Dr. Hood's case differed from one of ordinary pericarditis?

Sir ANDREW CLARK replied that Dr. Hood had not, he thought, introduced the case as having any special features as one of pericarditis, but as one of pericarditis ensuing on angina.

Dr. EWART observed that it was a question how far analogous symptoms to those of angina might be caused by dilatation of the heart and large vessels. He had met with cases in which cardiac pain was brought on by excitement, as in a case mentioned. Deposition of fibrin resulting from injury of such an organ might produce an amount of irritation equal to setting up pericarditis, and in an enlarged aorta, or a ruptured aneurism, the antecedent conditions necessary might be found.

Mr. COODE ADAMS made the suggestion that fatty degeneration of the heart might bring about the result described; extravasation through a rent in one such case had been described.

Dr. HOOD explained, in answer to Sir Andrew Clark's query that he saw the case on a Sunday night, and was unable to obtain nitro-glycerine to administer. Temperature was normal throughout. The urine was of good density, and there was no arterial degeneration.

Dr. DE HAVILLAND HALL on a case of

EMPYEMA FOLLOWED BY ABSCESS IN THE BRAIN.

S. N., æt. 19, a pupil teacher, admitted into the Westminster Hospital, August 20th, 1883. The patient had empyema following an attack of acute pleurisy three years previously. She had been tapped, and a drainage-tube left in. When first seen by Dr. Hall at Christmas, 1881, she was suffering from hæmoptoe in consequence of imperfect flow of pus; immediately, however, that perfect drainage was established, her condition improved, and for a year she was able to resume her duties. The reason of her last admission into hospital was the hope that the chest had sufficiently fallen in to allow of the withdrawal of the drainage-

tube, but when this was done the evening rise of temperature which occurred showed that pus was accumulating, and the tube had again to be introduced. Just as the patient was about to return home she began to complain of headache; this was followed by vomiting. On the 11th day from the onset of cerebral symptoms the temperature, which previously had been subnormal, began to rise. There were slight convulsions on the left side of trunk and face, the drowsiness became more profound, and she died comatose. Shortly before death there was a copious purulent discharge from the left nostril. At the post-mortem examination, which was made by Dr. Hebb, the left pleura was found extremely dense, a cavity capable of containing several ounces of fluid lay between the opposing surfaces, elsewhere the parietal and visceral pleura were united. On removing the brain, an abscess in the left posterior lobe burst; no other pathological appearance was detected. The abscess, spherical in shape, and about the size of a hen's egg, lay in the white matter, the walls were nearly an eighth of an inch thick, hard, and of a purplish brown colour; the contents were a thick greenish pus, which had an offensive odour. In commenting on this case Dr. Hall insisted on the importance of having a double opening in cases of empyema, the lower one being made, if possible, in the eleventh interspace—a drainage-tube being passed through the two openings, and the ends tied together. By this means perfect drainage is attained. He claimed the case under consideration as a success, so far as the empyema was concerned, as the treatment was so far beneficial that the patient was able to resume her duties; whereas, prior to the double opening being made, she was much exhausted by the constant suppuration, and consequent hectic. Turning to the question of cerebral abscess, Dr. Hall mentioned some cases in which this disease had followed empyema. In his case the thick abscess wall pointed to its being of many months duration; the absence of symptoms till towards the end being explained by the seat of the lesion being at a distance from the motor and sensory centres, which apparently were not compressed. The two symptoms which ushered in the terminal period, viz., headache and vomiting were those commonly observed in such cases. He was unable to give any explanation of the discharge of pus noticed from the left nostril shortly before death. At the autopsy in spite of careful search, no appearance of suppuration was detected at the base of the brain, and there was no communication between the abscess and the nose.

Dr. BURNLEY YEO expressed himself strongly in favour of Sir Joseph Lister's operation in cases of chronic empyema, whereby a free incision is made and a portion of the seventh rib excised in the axilla. In his own practice this plan produced good results, and three cases were instanced by Dr. Yeo in proof. He wished to know how Dr. Hall regarded this operation. German authorities selected the fifth interspace in front as the point of operation, because of difficulty arising in old-standing cases from the thickened deposits found in the axillary region.

Mr. PARKER pointed out that no particular spot could be named as suitable in all cases, and that empyema should be treated where found. In empyema of the whole chest, however, he preferred Dr. Yeo's plan to that indicated by Dr. Hall. Had the case narrated by the latter been under his care he would have been dissatisfied with any less result than a cure, which he thought ought to have been obtained in it. When operating in such cases he made a single opening, into which he inserted two drainage tubes to promote free discharge of pus. No portion of rib need be removed if the opening made were large enough. He found good results to follow from well scraping the cavity in old-standing cases.

Mr. PEARCE GOULD considered the unsatisfactory termination of the case should not be credited to the operation, which was, in itself, successful. It was difficult to explain the abscess of the brain in association with empyema, but it had to be admitted that it was septicæmic, as shown by the temperature chart of the case. Mr. Hulke, he observed, regarded the existence of subnormal temperature with headache as indicative of intra-cranial suppuration. Was any tubercle of the brain found in Dr. Hall's case? He agreed with Mr. Parker that all cases of empyema were not alike, and thought encouragement to operate in the 11th interspace in some cases was found in the fact that the diaphragm did not in this situation interfere, a cavity remaining there. Moreover, where the wall of the chest collapsed in an empyema, the 11th interspace was the only spot where a wide space

existed, the diaphragm not being adherent, so that good drainage might be secured there. He believed it would have been a good plan in Dr. Hall's case to have left the upper tube in place instead of removing it. Commenting on Mr. Parker's plan of employing two tubes, Mr. Gould instanced the case of a gentleman on whom he operated, making a single free opening in the post-axillary line, inserting only a single tube. The patient, though much reduced, made a good recovery.

Mr. GODLEE thought it rash to ascribe the brain abscess to the empyema unless examination had been made to discover a suppurating spot in the ear or nose. He approved the removal of portions of three ribs in some old cases of empyema, thus affording an ample opening for free drainage. Two tubes would not be called for if the single opening was made sufficiently large. In one case he had operated on, and which died from other causes than the empyema, he found a formation of new bone progressing.

Mr. BARKER advocated excision of part of the rib to prevent nipping of the drainage tube during collapse of the chest wall. There would be no difficulty in obtaining free drainage, provided the opening was sufficiently large. In one case he removed parts of three ribs, and in it complete renovation of bone occurred; and in young subjects especially such a proceeding could be recommended.

A MEMBER said he had seen two instances within the last year in which cerebral abscess followed empyema treated by removal of rib.

Sir ANDREW CLARK said the discussion had brought out the fact that, under certain conditions, inflammation might occur without a rise of temperature; and also that septicaemia and even fever might exhibit an assemblage and progression of symptoms without exaltation of body heat. In the London Hospital, recently, was a young married woman with phthisical family history, who had been five times operated on at Guy's, and then sent to the country. She returned with a dry pleuritic rub over the whole right chest. With rest in bed she improved, and one large opening was then made in the lower part of the axilla. She was discharged well; right lung natural. While wearing the tube she exhibited small storms of fever, which always subsided on the removal of small accumulations of pus, to which they were due.

Dr. HALL said consideration was given, before operating in his case, to Dr. Burney Yeo's suggestion, the lower opening having been purposely selected. It should be remembered, in judging the result, that the case was one of fistulous empyema, and had been progressing sixteen months before it came under his care; and in such a case the low operation offered the most favourable chance. The wall of the cerebral abscess was one-eighth of an inch thick, and must have, therefore, been some time in formation. There was no evidence of tubercle in the brain, nor of any diseased bone at the base of the brain, in the nose or ear.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY. FRIDAY, JANUARY 4TH.

Dr. THUDICHUM, President, in the Chair.

Mr. T. PICKERING PICK read the notes of a case of
STONE IN THE BLADDER OF A FEMALE.

Seven years ago the patient was admitted into one of the London hospitals suffering from symptoms of stone in the bladder. An operation was performed for removal of the stone, and ever since she had suffered from incontinence of urine. Several plastic operations had been performed for the cure of the incontinence, but without success. Two years ago an opening had formed between the rectum and vagina, and ever since the faeces had passed from the one tube to the other. When she came under Mr. Pick's care he found that the whole of the posterior wall of the bladder had been destroyed, as well as the under surface of the urethra. There was also an opening the size of a goose-quill between rectum and vagina. As there appeared to be no probability of closing the vesico-vaginal fistula, Mr. Pick occluded the vagina by removing a circular belt of mucous membrane from just within the orifice and bringing the raw surfaces together with quilled sutures. The operation was attended with marked success, the patient passing her water by the rectum, and being able to retain it "as long as she liked." Mr. Pick then

remarked how unadvisable it was to use gradual dilatation, or, as proposed by some, to slit up the urethra, in that these methods usually resulted in incontinence. The rule, he thought, should always be to dilate rapidly for stones not larger than a filbert, while for stones of larger size lithotomy is preferable to lithotripsy.

Mr. LUNN mentioned how difficult it was to perform lithotripsy in young children, owing to the danger of injuring the bladder.

Mr. HOWARD MARSH asked Mr. Pick as to how his patients bore the urine in the rectum. He also remarked upon the difficulty of turning the instruments sufficiently to crush the stone in the bladder of a child, and mentioned that frequently the fistulae were due to syphilitic ulceration, and therefore impossible to heal.

Dr. HART VINEN and Mr. LLOYD also spoke.

Mr. PICK, in reply, said that he found his patients bore the urine in the rectum exceedingly well, and mentioned a case of recto-vesical fistula due to gonorrhoea in a young man in which the rectum became, as it were, a secondary bladder, and lasted for many years with but slight inconvenience.

CARIES OF THE SPINE MISTAKEN FOR MORBUS COXÆ.

Dr. CLIPPINGDALE showed a case illustrating the difficulty of diagnosing between caries of the spine leading to psoas abscess and disease of the hip joint. The patient, a boy, æt. 11, had been in no fewer than four of the London hospitals, where he had been treated by plaster of Paris jackets applied to the back, and weight and pulley attached to the leg, and his friends had been informed at the various institutions that he was suffering from spine disease, from hip disease, or from both hip and spine disease. Dr. Clippingdale and his colleagues at the Kensington Dispensary had treated him for disease of the hip-joint as well as for caries of the spine. Yet, now that many of the sinuses had ceased discharging, it was perfectly clear that each hip-joint was perfectly intact, and that all that had occurred was caries of the lowest dorsal and uppermost lumbar vertebrae. This disease had apparently given rise to a psoas abscess on each side, and this in time had occasioned sinuses around each hip-joint similar in situation to those produced by morbus coxæ. There had also been some ostitis of the great trochanter upon the left side, which had evidently helped to produce the error in diagnosis.

EXCISION OF THE HIP.

Mr. POTTER showed a living specimen after excision of the hip. The patient was a boy, æt. 8, who had been the subject of hip disease for three years. He was admitted into the Kensington Infirmary four years ago, and on account of the pain induced by the disease and extensive suppuration telling upon the powers of the patient, the joint was excised. Mr. Potter, in detailing the steps of the operation, said he removed the head, neck, and the upper part of the great trochanter, and finding in the acetabulum a loose sequestrum, also took this away. The wound healed completely in nine months, and the patient had since been walking about without a crutch. The shortening was 2 3-8th in. So little inconvenience had resulted from the operation that the patient, with the aid of a high boot, ran up and down a passage before the members of the Society without pain. The normal movements of the joint were only slightly modified; that of abduction was decidedly lessened. A few days since the boy fell, and ruptured a cicatrix in the groin; with this exception no sinus existed.

Mr. J. R. LUNN then read

TWO CASES OF HIP DISEASE.

I.—Susan G., æt. 10, was admitted to the St. Marylebone Infirmary in October, 1883, with old hip disease, and small sinus over the left femur. She was quite well until four years ago, when she fell on her left hip, and has been lame ever since. She had had three or four operations performed by Mr. Beck at University College Hospital, where she was ten months. She was then a patient for three years at the Incurable Hospital, Chelsea. On admission, child looked very anæmic, had ankylosis of left hip, no apparent shortening, old scars about the hip, and one small sinus still open, some lordosis with lateral curvature towards right; viscera normal. She could stand on her left leg when supported. There was also some wasting of gluteal muscles.

II.—R. J., æt. 28, single, a laundry-woman, was admitted into the St. Marylebone Infirmary in December, 1883, with hip disease. She had always had good health until three years

ago, when she had an accident and fell through some glass and cut her right arm severely. She was taken to St. George's Hospital in an unconscious state, and was confined to bed for six months with her arm. When she got up she noticed that her right leg was painful, causing her to limp. In February, 1883, she went to St. Bartholomew's Hospital, where she was treated with an extension for four months, and was told that she had hip disease. She then went to Margate Infirmary, and on admission there appeared to be a fairly healthy woman. She had old scars on her right arm and wedge-shaped incisor teeth. There was no flattening of the buttocks, $1\frac{1}{2}$ in. shortening of the right leg, and she was able to stand on her right leg when supported. There was also incomplete ankylosis of the right leg.

Dr. THUDICHUM, speaking, laid great stress upon the use of the stethoscope in such cases, as by means of that instrument one can generally tell the nature of the disease. Thus, when the stethoscope is placed over the joint, one will hear a distinct grating of the bone when there is hip disease, but if it be due to rheumatism, one will hear a specific soft grinding noise, somewhat like the murmur of a distant engine.

Mr. HOWARD MARSH, speaking of the diagnosis of these cases, strongly advised putting the patient through all the natural movements of the spine, such as making the patient run upstairs, lie down on the back and get up again, the enarthrodial movement being of the greatest importance.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 30, 1884.

THE TERMINOLOGY OF PHTHISIS.

NOTHING so much conduces to an accurate comprehension of disease, and especially of the phenomena which characterise the varying phases of allied diseases, as the employment of a definite and easily-applied terminology. Notwithstanding that the habit of thinking of disease as an assemblage of signs and symptoms, without relation to the name denominating it, is inculcated by all good teachers, and undoubtedly is observed

by every capable clinician, it is still essentially true that as increase of knowledge enables stricter application of words to things, so does the progress of medicine advance; the two, indeed, proceed *pari passu*. It was in some such spirit of reflection as this that Professor Virchow recently indulged when addressing the members of the Berlin Medical Society on the Infectiousness of Tuberculosis, a translation of the speech delivered on this occasion having been published in our issue of Jan. 9th. For a long time, and especially since Koch's epoch-making discovery, pathologists and clinical observers have evinced an obvious dissatisfaction at the loose manner in which the terms "tubercle" and "tuberculosis" are employed; and the same disinclination to accept the use of phrases which are not etymologically exact has evidently occurred to the great master of German science, who emphatically denounces the system by which encouragement is given to misapplication of names.

To a majority of physicians the word phthisis calls up a mental picture of a certain definite kind, while to most it suggests also a division of the general disease into species each possessing distinctive features of its own. Guided, moreover, by deeper researches into the origin and progress of the affection, they now very usually assign to "tubercle" the rôle of an active producing agent in one form of phthisis; and for the most part they here close the process of analysis which has led them to the formation of a diagnosis. Strictly speaking, however, there is no ground for such a proceeding, since "tubercle" is literally nothing more than a diminutive "tuber," or a small nodule, and is equally appropriate for designating any minute mass-growth, wherever found. Previously to the creation of an interest in the existence of bacilli within the body, universal acceptance gave the term "tubercle" a particular meaning of its own, which, though founded solely on usage, was sufficiently definite to be generally serviceable; though not on that ground to be defended. Now, however, in the presence of the knowledge which shows that the growths formerly denominated "tubercle" have an invariable association with the bacteroid organism bacillus, it is both desirable and essential to throw aside the loose system of names in this connection, and to assign to the products of the disease a distinctive and descriptive epithet.

Not every "tubercle" or little nodule found in the body as a result of morbid action is "tuberculous," in the sense of its being a focus of bacilli development; and hence, if we should continue to misapply a term long misapplied harmlessly, it cannot fail to breed confusion in the minds of those who will come to regard it in the future as synonymous with bacillus infected deposits. To avoid so undesirable a result, the adoption of Virchow's proposal would be at once wise and generous, involving only a slight amount of present inconvenience, with a view to smoothing away difficulties from the path of newer generations of students. The suggestion made in this connection by Virchow is to replace the word tubercle by "bacillous," and so give a definite and restricted meaning to the term when employed to designate that which it is really intended to convey.

Thus, supposing that phthisis is the disease in question, and that particular form of phthisis hitherto called tubercular, it would henceforth, at Virchow's instigation, be known as "bacillous" phthisis; and thus the name given to it would immediately recall the main facts distinguishing it from other and non-bacillar varieties of the affection. That much simplicity of meaning would be introduced under this plan does not admit of doubt; but its principal support is found in the freedom from misapprehension as to the real points to be conveyed in the description.

On several occasions proof has been given of the importance to be attached to an accurate terminology of disease; and though it sometimes happens that too little regard is had to this by inventors of new names, yet there is tacit acceptance of the principle on all hands. It will necessarily follow, moreover, that many diseases must, when first fairly brought to notice, be dubbed with names which, when their etiology and pathology are better understood, will be found manifestly inappropriate. To admit the truth and to correct the error committed in ignorance is surely to advance in the path of improvement, and, at the same time, to make the literature of medicine more perfectly representative of diseased conditions. We fortunately hear very little now of declamation against the uselessness of words in the profession of medicine. As a matter of fact, words are of priceless value in this connection; but also it can be said that they may be made the instruments of vast evil. The best teachers are they who use their words as they would use their instruments or their drugs—each one in its exact place, and each with a view to achieve a distinct and exactly-defined purpose. Thus utilised, they convey meanings which cannot pervert the truth, as truth is contemporaneously understood; they enforce it, and assist its reception in the mind of the student and observer.

THE ACADEMY OF MEDICINE OF IRELAND.

EVERY well-wisher of the Dublin School must rejoice at the large measure of success that has attended the formation of an Academy of Medicine in Ireland, and feel a pardonable sense of pride at the encomiums that have been bestowed on the first volume of its Transactions by so many competent critics in England, Scotland, and the United States of America. The work done in the various sections of the Academy is such as will undoubtedly enhance the reputation of a School which, previous to the foundation of the Academy, was fast lapsing into a state of regrettable torpidity. However, though we must rejoice that a much healthier condition of things now exists, and that evidence is afforded at every sectional meeting of a zeal, activity, and earnestness in furthering every branch of medical science, there is a circumstance which cannot escape the notice of even the most casual observer at the meetings of the Academy, viz., that with one or two exceptions, the work done is by the junior or comparatively junior members of the profession. This is a fact which is much to be deplored, and we think the time has arrived to inquire why this state of things should be. In all other great centres—

London, Paris, Edinburgh, Berlin, Vienna, New York, &c.—the leaders of the profession—those in whom the public place the greatest confidence—are among the most active of the members in contributing papers and taking part in debates and discussions on them. Why is it that in Dublin so many of those who have obtained foremost places in the front ranks of public practice, men of intelligence, of ripe experience, and whose discretion and abilities are unquestioned, should at all the meetings of the Academy be conspicuous by their absence? This was not formerly the case in the days of the old Pathological and Surgical Societies of Ireland, where the acknowledged heads of the profession were invariably present, ever ready to sympathise, aid, and encourage by their example.

When we compare the records of the London societies with those of our Academy, we cannot but be sensible of the fact that, whereas in London the acknowledged leaders of the profession exhibit an energy and activity which is worthy of all praise and recognition, in Dublin, alas! their analogues are apparently indifferent, but certainly mute. This is a more serious matter than would appear at first sight. A persistent ignoring of and indifference to medical scientific progress on the part of those who ought to be teachers and pioneers is most discouraging to those willing and able to do original work, and who cherish the hope of accomplishing some work in the future that may maintain or perhaps enhance the fame of our School.

Recently, on State honours being given to our profession, a widespread dissatisfaction was felt and expressed at the neglectful way Ireland was treated, but when the leaders of the profession in Ireland adopt a principle of self-effacement in all efforts made here to advance medical science, one cannot be altogether surprised if the State, in distributing honours, should ignore them.

While, however, we deplore this want of scientific ardour in the majority of the leaders of our profession in Ireland, we must guard ourselves from the inference that we attribute that indifference to any feeling of ill towards the Academy or its administrators. We rather think that the energy displayed by the heads of the profession in other parts of the Kingdom and the absence of the same energy in Ireland are the natural result of the differences in our systems of medical practice. In London the consultant is fully conscious that he lives by the patronage of the general practitioner, and that if he desires to retain that patronage he must from time to time remind the rank and file of the profession of his existence and of his scientific progress by appearing at medical gatherings and in the professional periodicals. In Ireland, on the contrary, the consultant lives by the confidence reposed in him by the public at large, and he thinks, unwisely we believe, that that confidence would not be increased or extended by anything he might do to attract the admiration of his own brethren. Therefore, as a rule, the Irish consultant writes little, speaks little, and mixes little in scientific converse with his brethren, and perhaps we may say in some cases, reads little. A more short-sighted policy could not be adopted, for it must be

obvious that the physician or surgeon who elicits the respect and admiration of the general body of the profession by his devotion to the science and art which he practises stands on much safer ground as regards practice and income than he who depends upon the fancies of the public. There are men in Ireland who could double their incomes by taking their proper position at the head of the working practitioners of the country, and it is greatly to be regretted that they remain satisfied with the commonplace honour of a sufficient income when they might raise themselves and the Irish School in public estimation by the exercise of a little more zeal and a little less selfishness.

THE DEMORALISING AND PAUPERISING INFLUENCES OF HOSPITALS.

AN interesting correspondence on the above subject has been recently carried on in the columns of our able contemporary the *Scotman*, initiated by "M.D.," who, *inter alia*, apropos of the Report of the Edinburgh Royal Infirmary, states: "Apparently it never enters into the minds of any concerned to ask whether any such increase [of patients] be occasioned by a real need for gratuitous medical advice on the part of the applicants, or whether these institutions themselves may not be fairly charged with creating this increased demand by the utter want of any system of control, or any attempt to determine the means and status of the applicants. As the result of experience and inquiry, there is much reason to think that our medical institutions are really pauperising a section of the community by assisting such as are well able to pay a medical adviser; are misapplying the contributions of donors, and are also acting most unfairly towards the general practitioner."

With these sentiments we entirely agree, and in a subsequent letter on this subject it is pointed out that artisans earning from 25s. to 35s. a week should pay for medicine and medical attendance. We hold with the writer, that artisans earning any such wage have no more reason nor right to expect free medical attendance and medicine than they have to demand that they should be supplied *gratis* by their butcher or baker. The results of this excessive medical charity are only too apparent. As a rule, the working classes are shamefully pauperised in this manner, habits of dissoluteness and improvidence are begotten, and drunkenness and crime are rampant, while a large section of the medical profession are unjustly robbed of their just due. In the city of Glasgow, for instance, within the past thirty years, working class practice has all but disappeared, having been drafted to the large hospitals to further the personal ends of those whom the accident of birth or fortune may have raised above the need of such practice. The extent to which this has taken place is shameful and scandalous in the highest degree, and the only cure which we can see for it is the encouragement of the provident system of medical relief among the humbler orders. It is perfectly true that the profession itself is not blameless in the matter, and it is much to be deplored that well-meant benevolence is not directed with more judgment and wisdom.

From this stage, however, to compulsory payment in all cases is an abrupt step which has been taken by the authorities of Guy's Hospital, who have just introduced so novel a change in the mode of administering the charity under their charge, that it may well become matter of wonder to what extent they may not by and-by proceed. Henceforth all out patients are required to contribute threepence towards the hospital funds, in return for the assistance given to them; and those who obtain medicine to go over a fortnight must pay sixpence. As, however, it must sometimes happen, even at Guy's, that patients of extreme poverty will present themselves for relief, and be in a position to need it imperatively, the authorities have hit upon the happy (!) plan of co-operating with the Charity Organisation Society, and will now require the latter body to set its *imprimatur* on every letter given to patients who are unable to pay. The Charity Organisation Society is a most excellent institution in its way; but, nevertheless, we doubt somewhat whether such a partnership as that arranged between it and Guy's is either advisable or legitimate. At any rate, it is unquestionable that the new regulations formulated at the hospital meet with anything but approval from the poor who have to apply to it for medical help; and in addition to this we fail to see the advantage that will accrue to the charity from such pitiful augmentation of its funds as will result from its competition with fourpenny dispensaries. Moreover, the question still remains, Is the charge a legal one?

Notes on Current Topics.

The Medical Bill.

It is generally understood, in well-informed quarters that the prospects of the Medical Acts Amendment Bill in the coming Session of Parliament are of the most encouraging description. The Government is fully determined to introduce the measure as soon as an opportunity of doing so presents itself, and it may reasonably be presumed that a valuable lesson will have been learned from the disasters which marked its progress last year. Already, too, signs are not wanting to indicate that opposition is marshalling its forces in preparation for the fray; and probably the Bill will encounter a good deal of rough weather ere it is steered safely into port. Whatever may result, however, there seems to be no question entertained respecting the reality of the renewed attempt to pass the measure into law; but a good deal will doubtless depend on the nature of the modifications to be introduced into its provisions in consequence of the experience gained last year. It is something, and a good deal, to be assured that those in charge of it are not dispirited at the poor amount of success already gained, but are prepared to begin anew to fight the battle of reform against the Corporations. We would earnestly hope that time will have tempered the extravagance of a few of these bodies, and that their demands will be pitched in a much lower and more becoming key than on the last occasion when they were uttered. It will now be speedily known what are the

real intentions of the Government, and much justifiable curiosity is naturally felt concerning them.

Electric Railway Lighting.

RAILWAY travellers accustomed to the misery of ill trimmed, feebly-illuminating oil lamps in the carriages of trains will rejoice to learn that some prospect of relief is at last opening before them. Especially will South London travellers by the lines running out of the great city termini hail any indication of a possible era of improvement in this respect; for no one who is used to the dimly visible darkness of an ordinary London, Brighton, and South Coast train will be at a loss to understand what an era of absolute comfort will set in when electricity is adopted in place of the dirty and inefficient lamps now employed. Rumours have, indeed, for some months past been current respecting trials of various schemes on one or another of the north-running lines, but none of the plans proposed seem to have been found successful. Lately, however, on the District Railway, a direct method of lighting trains by electricity has been under experiment between Kensington and Putney, and a fortnight's trial has shown it to be completely feasible. When fully perfected the apparatus will be worked with steam from the locomotive, a special engine, small in size, but of high speed, being situate, with the dynamo, on the tender. When this mode of lighting trains once becomes general, it will in all probability lead to material diminution in the amount of injury caused to eyesight by straining attempts to read the small type of evening papers by aid of flickering oil lamps, a cause which is to blame for not a little of the disease found among middle-class patients.

The Social Science Association.

THIS body is early in the field this year in making arrangements for the next congress, to be held in Birmingham in September. The secretary of the Association has already visited the midland town, and conferred with the Mayor and others as to the public buildings to be placed at the disposal of the Association for the purpose of the congress. The Mayor will preside, and a deputation from the council, consisting of Sir Richard Temple, Bart.; Mr. Hastings, M.P.; and the Rev. S. Alfred Steinthal, will attend and deliver addresses on the objects and work of the Association.

The late Mr. Wheatley.

THE general regret experienced through the death of the Royal Medical and Chirurgical Society's resident librarian has, in the case of the Society itself, led to a practical expression of the sense entertained of the late Mr. Wheatley's services. We understand that it is in contemplation to establish some description of memorial by which the deceased officer's devotion to the interests of the Society for forty years shall be kept in mind. A movement of this kind is at once a graceful and a well-deserved tribute of respect to the memory of one who had been so long identified with the Society; and it is pleasant to find that the tribute is so heartily and spontaneously to be offered. At a special meeting of the Council of the Society, held on

the 17th inst., the following resolution was unanimously adopted:—"The Council of the Royal Medical and Chirurgical Society of London desire to express their sorrow at the sudden and unexpected death of their late excellent resident librarian, Mr. Benjamin Robert Wheatley, and their sympathy with the surviving members of his family. The Council also wish to record their deep sense of the value of his services to the Society during the last forty years, and their due appreciation of his constancy and fidelity in the discharge of his important duties."

The Cure of Hernia by Injection.

DR. JOSEPH H. WARREN, of Boston, Mass., has recently published, through Messrs. J. & A. Churchill, a small work, entitled "A Plea for the Cure of Hernia," which well deserves to be carefully studied by surgeons. The principal object of the brochure is to describe and advocate the author's mode of curing hernia by means of subcutaneous injection of an astringent fluid into the hernial canal and around the sac. Dr. Warren cautions his readers against the common error of injecting the sac itself, whereby peritonitis is necessarily set up, and the operation jeopardised. Dr. Warren employs a special form of syringe, the nozzle of which is so constructed that it turns in the hernial cavity, and, terminating in a rose, the contained fluid is well scattered throughout the surrounding structures. The solution most commonly employed consists of quercus alba, with alcohol, ether, sulphate of morphia, and tincture of veratrum viridis. It acts by creating an irritative inflammation in the fibrous tissues, and thus adhesion among them is promoted. After eight days from operation the patient wears a special truss, devised by Dr. Warren, and called by him the anatomical truss, which is discarded in about three months, and cure is complete. Dr. Warren has been most successful with this method of treatment.

The Effect of the Pro-Contagious Disease Agitation.

VENEREAL of the most virulent type (says the *Army and Navy Gazette*) is still the prevailing disease among the troops at all the military stations. At Aldershot, considerably more than one half the patients in hospital are suffering from this disease, which is steadily on the increase. On the other hand, the Lock hospitals are almost empty. Attendance at these institutions being now optional, but few unfortunates present themselves for treatment, and these, as a rule, are only very bad cases. Fostered and encouraged as it is, this loathsome disease is spreading to such an extent as to cause grave anxiety.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 29, Bombay 25, Madras 42, Paris 24, Geneva 28, Brussels 24, Amsterdam 30, Rotterdam 30, The Hague 22, Copenhagen 24, Stockholm 24, Christiania 7, St. Petersburg 35, Berlin 23, Hamburg 30, Dresden 26, Breslau 29, Munich 27, Vienna 31, Prague 35, Buda-Pesth 27, Trieste 29, Rome 30, Turin 25, Venice 34, Lisbon 41, New York 24, Brooklyn 19, Philadelphia 24, and Baltimore 25.

The Testing of Practical Study.

THE following important addition to the existing rules respecting the admission of candidates for the Licence in Medicine of the King and Queen's College of Physicians has been adopted, and the necessary amendment of the by-law made accordingly: "Every candidate for the Licence in Medicine in this College who shall commence his professional studies after September 30th, 1883, shall submit evidence of personal attendance on at least five fever cases; and shall also be required to produce evidence showing that he has discharged the duties of medical clinical clerk during six months, or of having taken notes, to the satisfaction of the physician in charge of the case, and certified under his hand, of at least six separate medical cases—including different varieties of acute and chronic disease—in the wards of a recognised hospital; and shall also produce evidence of having attended, during the whole period of his attendance on hospital practice, demonstrations in the post-mortem room of a recognised hospital."

Pro Utilitate Hominum.

WE are glad to see that the St. John's Ambulance Association has started on a new sphere of usefulness and enterprise in the organisation of a corps for the transport of sick and injured patients. Hitherto, if a person of means met with an accident in the streets of London which necessitated his removal to a hospital or to a distant home, he had to be submitted to the discomfort of a journey in a cab, a lumbering invalid carriage which was equally suggestive of a hearse and a mourning coach, or he had to be carried in any way which chance or expediency might dictate. Now all that he would have to do would be, telegraph to St. John's Gate, Clerkenwell, and he would have his journey arranged and effected for him on the most scientific and approved principles, and at a fixed and moderate cost. Or, should he find himself in a London hospital with a fractured thigh, and wish to be taken to his home, in Dublin, for instance, he could be placed on one of Mr. John Furley's litters, and not be disturbed again until he was gently and safely deposited upon his bed in the Irish metropolis.

Or, to take the case of a poor man, who, with a fractured spine, wished to be taken from a hospital ward to his bed at his own house, the Society would undertake the transport at a merely nominal cost. It seems to us that the Corps will find itself with plenty of work to do as soon as the profession and the public become aware of its establishment, and we wish it all success.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 20.7 per 1,000 of their aggregate population. The death-rates in the several towns were:—Wolverhampton 11; Blackburn, Portsmouth 15; Halifax 16; Bradford, Hull 17; Bolton, Nottingham, Bristol 18; Newcastle-on-Tyne, Derby, Leeds 19; Plymouth, Norwich, Birmingham, London, Edinburgh, Liverpool 20; Brighton 21; Huddersfield, Leicester 22; Oldham, Sunderland, Preston 23; Salford, Birkenhead 24; Sheffield, Cardiff 25; Dublin, Glasgow 26; Manchester 27.

The Royal Irish University.

DR. CHARLES F. KNIGHT, M.D., of Dublin, has issued a circular to the Senate of the University, in which he announces that, at the coming meeting of the Senate, three resolutions, proposed by him for acceptance by Convocation at the last autumn meeting, will be brought before the Senate. The first resolution is, "That the Senate be requested to consider the advisability of holding the medical examinations in the months of May and November in each year." The months of June and September are those in which the medical examinations are now held; these follow one another too quickly, and are nothing but a pass and honour examination. It is obvious that the time between the two examinations is far too short for a student to make up his business, especially his practical work, as the medical schools and hospitals are virtually closed during the interval. The examination in June interrupts the summer course of lectures, and students cannot present the certificates of lectures delivered at this time, as the session is not over until the end of June. The September examination is held when professors and students are seeking a change of scene after the nine months' prescribed course of study. At this time of year our schools and hospitals are closed, our professors are absent, and opportunities for acquiring practical knowledge and for testing candidates in clinical work are wanting. These disadvantages may be obviated, and the usefulness of the University increased, by selecting May and November as the months for holding the examinations. The second resolution is, "That the Senate be requested to admit undergraduates of the University in the Faculty of Medicine to two examinations in the year." Dr. Knight thinks that a University which only affords one opportunity of obtaining its degree in the year will not for any length of time be in favour, and that this circumstance will drive men from its doors and send them to the licensing corporations, many of whom hold monthly examinations, and nearly all four examinations in the year. He says that, in consequence of unsuccessful candidates being rejected for twelve months numbers give up the idea of obtaining a University degree in despair, and go to the licensing bodies, and he understands that the principal objection to admit students to two examinations in the year comes from the examiners in anatomy, who very properly say that under existing regulations unsuccessful candidates in June, cannot, before September, obtain instruction in practical anatomy. If May and November are the months selected for the examinations, this objection is removed. The third resolution is, "That the Senate be requested to admit Undergraduates of the late Queen's University in the Faculty of Medicine to two examinations in the year." He considers that students of the late Queen's University are seriously hampered in the pursuit of their medical curriculum. The Queen's regulations provided for two examinations in the year, and required the fees for degrees to be paid only on the first occasion. If a candidate were unsuccessful he might present himself at a subsequent examination without paying again. The Senate of the Royal has thought it right to prevent such students presenting themselves for examination a second time in the same year, and insists on their paying fees at every examination. Dr. Knight does not

consider this equitable. The Queen's students have fulfilled their part of the contract, and the Royal may very reasonably be asked to perform the other part, which would have been done by the Queen's University if it still existed.

Lectures at the Royal College of Surgeons, England.

THE following are the lecture arrangements at this College for the first half of the year :—

Professor Parker will commence a course of nine lectures on "Mammalian Descent," on Monday, the 4th of February. Professor Flower will then deliver nine lectures on the "Principal Types of the Human Species," commencing on Monday, the 25th of February. And Mr. F. S. Eve will give three demonstrations on "Some Points in Pathology," illustrated by specimens from the museum, commencing on Monday, the 17th of March. The course of lectures will be concluded in June by Professor Sir Henry Thompson, who will deliver six lectures on "Some Important Points in connection with the Surgery of the Urinary Organs," and by Mr. A. E. Schafer, who will deliver three lectures on a subject to be hereafter announced.

The lectures, which are open free to members of the profession on presentation of their card, will be delivered on Mondays, Wednesdays, and Fridays, at 4 o'clock each day.

Adulteration.

THE Legislature of Massachusetts having passed a law for the prevention of adulteration, the State Board of Health has lost no time before trying to put it into force against the wholesale druggists. One charge was for selling tincture of opium that contained only 0.81 per cent. of morphine. This case was not tried on its merits, it having been dismissed upon the curious quibble that there was no evidence that the person who sold the drug was an "authorised salesman."

Coated Tongues.

THE *Microscope* gives the following as some of the articles found by microscopical examination on coated tongues :—Fibres of wood, linen, and cotton; fibres of spiral vessels; fibres of muscle, in one case eight hours after eating; starch grains; cheese mould; portions of potato skin; scales, moths, &c.; hairs from legs of bees; hairs from legs of spiders; pollen of various flowers; stamens of various flowers; hairs of cats, quite common; hairs of mouse, once only; hairs from various leaves; wing of mosquito, once; fragments of the leaves of tobacco, chamomile flowers, &c. A list ten times as long could be made, but *jam satis*.

THE Paris correspondent of a medical contemporary states positively that there is absolutely no truth in the report circulated freely by British opponents of legislation for checking the spread of venereal diseases, that the French Contagious Diseases Acts were to be revoked on January 1st, and that the Hôpital du Midi and the Lourcine at Paris, together with similar institutions in other French towns, were to be closed forthwith.

Bequests to Dublin Hospitals.

MR. JAMES BENJAMIN BALL, D.L., late of Merriion Square, Dublin, who died in October, 1883, at Nice, bequeathed the following amongst other legacies :—£3,000 to trustees to be distributed to any of the Irish charities, schools, or institutions they may think deserving; £1,000 to the Adelaide Hospital, Dublin; £1,000 to Mercer's Hospital, Dublin; £1,000 to the City of Dublin Hospital; £1,000 to the Rotunda Lying-in Hospital, Dublin; £500 to the Whitworth Hospital, Drumcondra; £300 to the Coombe Lying-in Hospital, Dublin; £200 to the Night Asylum, Bow Street, Dublin; and £200 to the Convalescent Home of Adelaide Hospital.

The Drawbacks of Hypodermic Syringes.

EVERYONE in the habit of using the now indispensable hypodermic syringe will have been incommoded in taking up one that has not been used for some time by finding that the packing round the piston valve has become loose by over-drying, and that it requires a few moments' soaking in water before it can be used. Although but a trifling inconvenience, this may be of more importance than appears at first sight, for if an attempt be made to use the syringe before the valve has become tight, a few of the drops intended for injection, instead of finding their way into the patient, will very likely slip past the valve, and the patient will be deprived of a certain—sometimes a large—proportion of the dose intended. For the sake of accuracy in the administration of concentrated and powerful medicine, then, and for the sake of convenience and time-saving, it is of some importance that the piston-valve shall always be in good working order. Various plans have been devised and tried having for their object the avoidance of this little drawback. One German instrument-maker now fits up his syringe with an air-tight cap, intended to be screwed on to the nozzle after the needle has been removed—something after the fashion of the cap of the "stylographic" pen. This prevents evaporation, and, of course, consequent drying and shrinking of the valve. But this plan, although ingenious and efficacious, involves the purchase of a new instrument; and for those who are content to continue their old one, the plan of a German surgeon may be tried. He says he has tried it many years, and finds it to answer well. When the instrument has been properly cleaned, and after the needle has been removed, he simply pulls out the piston-rod and completely immerses the whole syringe in clean water. He then, whilst the instrument is under the water, slowly pushes the piston down, and as this is being done the barrel of the syringe behind the valve fills with water. He then takes it out, dries it on the outside, and puts it into its case with the upper part of the syringe thus filled with water. Of course, under these circumstances, the valve cannot dry nor shrink, and the instrument is always ready for an emergency.

THE Annual Metropolitan Dinner of the Irish Graduates' Association will be held at the Holborn Restaurant, on St. Patrick's Day, at 7.30 p.m., the President, Prof. G. F. Yeo, M.D., F.R.C.S., in the chair.

The Hospitals Association.

THE following will be the order of proceedings at the inaugural meeting of this Association, which is to take place in the Egyptian Hall of the Mansion House on Friday next:—The Lord Mayor will take the chair at 3 o'clock, and after a statement by Major Ross, M.P., the chairman of the Provisional Committee, in explanation of the objects and scope of the proposed Society, the following resolutions will be submitted:—

1. That in the opinion of this meeting it is desirable to establish, under the name of the Hospital' Association, and on the basis of the constitution prepared and adopted by the Provisional Committee, an organisation for the consideration and discussion of matters connected with hospital management.

2. That the preliminary arrangements connected with the establishment of the Association, including the appointment of the first council, be entrusted to the Provisional Committee.

3. That the best thanks of this meeting be given to the Right Hon. the Lord Mayor for placing at the disposal of the Provisional Committee the use of the Mansion House, and for his courtesy in presiding over the proceedings this day.

The speakers will include Earl Stanhope, Lord Frederick Fitzroy, Sir T. Fowell Buxton, Bart., Sir Rutherford Alcock, K.C.B., Mr. Timothy Holmes, and others. The Provisional Committee desire very specially to invite the attendance of hospital governors and subscribers, and of the clergy, ministers, churchwardens, and other officials connected with congregations contributing to the Metropolitan Hospital Sunday Fund. A large number of cards of admission have been issued and applied for, and the Secretary of the Association, Mr. J. L. Clifford-Smith, will gladly supply more if those desirous of being present will communicate with him. The office of the Association is at No. 1 Adam Street, Adelphi, London, where further information can also be had.

THE collection made in Dublin on Hospital Sunday, November 11, 1883, amounted to £4,212—a sum considerably in excess of that realised the previous year. Something over £4,000 will be available for distribution between the sixteen institutions which participate in the benefits of the Fund.

MR. ROLAND WILLIAMS, L.R.C.P. and L.R.C.S. Ed, who was acquitted at the Bangor Assizes on Saturday last for conspiring with two other persons to defraud an insurance company to which he was a medical referee, was re-arrested at once on three other charges of fraud, and of issuing false certificates of death.

THE present exceptional healthiness of the United Kingdom does not appear to afford any index to the mortality in other parts of Europe. For instance, we have Geneva and Lisbon giving a death-rate for the week ending January 5th of exactly double the births; whilst in Prague, Rome, Vienna, Buda-Pesth, and Turin the births and deaths are nearly equal.

Virchow on Nephritis Arthritica.

THIS subject, about which so much diversity of opinion exists, has much engrossed the attention of our distinguished German *confrère* of late, and at the last meeting of the Berlin Medical Society, in December, he delivered an important address, in which will be found his matured views and experience. This communication we propose laying before our readers in translated form next week.

The Hunterian Oration.

WE understand that Professor John Marshall, F.R.S., President of the Royal College of Surgeons of England, has been appointed to deliver the oration at the College in 1885, in honour of the illustrious Hunter. This oration, which was formerly an annual fixture, is now delivered each alternate year, and the choice of Professor Marshall is in every way a most happy one.

Professor Frerichs.

IN April next Professor Frerichs will celebrate the 25th anniversary of his appointment as Director of the first Berlin University clinic. His colleagues and the medical profession of the city generally are already making active preparations with a view of giving such an expression of their sentiment on the occasion as will to some extent at least correspond to the very high esteem in which their distinguished *confrère* is universally held.

A Living Child after Craniotomy.

AT the meeting of the Royal Society of Physicians of Berlin, of the 18th inst., Dr. Breus exhibited a living child 18 days old on whom craniotomy had been performed. The conjugate diameter of the mother was 9 ctm. (3½ in.). On extraction by the forceps the left frontal bone was fractured during its passage over the promontory. the child, born asphyxiated, quickly recovered, without any paralysis and without pyrexia. The mother also made a good recovery.

The Centenary of the Irish College of Surgeons.

ON the 11th of February next the Irish College of Surgeons will have completed its 100th year of existence from the date of the grant of its first charter, but a considerably longer period since it was charged with public functions as "The Dublin Society of Surgeons." We understand that Mr. Wheeler, the President of the College, in order to mark the occasion, has invited the Lord Lieutenant—Earl Spencer—to a banquet at the College, and the invitation has been accepted by His Excellency. A large number of the heads of Departments—Judges, members of Parliament, and Irish Nobility, as well as the Council, Examiners, and Professors of the College, have been invited to meet His Excellency. The entertainment will, we anticipate, be worthy of the occasion, and of the President's hospitality, but we should hope that the Council will also honour the occasion by holding a *conversazione*, and will not permit the occasion to pass away without making it a red-letter day in their Calendar, and giving the Fellows of the College an opportunity of wishing the College prosperity and a long career of usefulness. It is not every such institution which can congratulate itself on having outlived a hundred years of difficulties and responsibilities, and it would be greatly to be regretted if this very special occasion for glorification should pass by without public gratulations.

DIPHTHERIA is again very prevalent in Berlin, sixty-three deaths from this zymoticalone having occurred there last week, which is nearly double the number recorded in the whole of the United Kingdom.

THE forthcoming Health Exhibition should be a great success, if money can guarantee it. In addition to those guilds of the City of London whose donations have already been announced, £3,562 was voted by other Companies last week, and £5,565 guaranteed in addition.

As Emeritus Professor of Clinical Surgery to the London Hospital Medical College, Mr. Jonathan Hutchinson, F.R.S., will deliver a course of six lectures in the anatomical theatre of the College, at 2.45 p.m., on Wednesdays and Fridays in the first three weeks in February, beginning on the 6th.

A SAD case of poisoning by mistake occurred at Ramsey, Isle of Man, on Friday last, when a retired merchant of Leeds, Mr. Thomas Reynolds, took by mistake a wineglassful of a liniment composed of aconite, chloroform, and opium, which was on the dressing table, instead of his proper medicine. Medical assistance was promptly obtained, but he died in about two hours.

THE studies of female medical students in Russia are not prosecuted under the most favourable conditions. A telegram states that all those now in St. Petersburg have been compelled to take up their residence in a large boarding establishment, provided by the authorities, instead of being free, as heretofore, to live where they please. They are to be at home before nine o'clock in the evening, under penalty of exclusion from the medical course. The dread of Nihilism permeates every rank and condition of life in Russia.

THE highest annual death-rates in the large towns last week from diseases of the zymotic class were—From scarlet fever, 2.8 in Sheffield, 2.4 in Leeds, and 1.6 in Salford; from measles, 2.6 in Salford, 2.3 in Birkenhead, and 1.7 in Oldham; from whooping-cough, 3.0 in Huddersfield, 1.8 in Brighton, and 1.4 in Newcastle-upon-Tyne; and from "fever," 2.2 in Cardiff, 1.9 in Blackburn, 1.3 in Salford, and 1.1 in Preston. The 39 deaths from diphtheria included 16 in London, 8 in Glasgow, 3 in Edinburgh, and 3 in Hull. Small-pox caused 6 deaths in Sunderland, 5 in London, 4 in Birmingham, and 4 in Liverpool.

THE annual general meeting of the Dublin Branch of the British Medical Association will be held to-morrow (Thursday), the 31st, at 4 o'clock p.m., in the College of Physicians. The President-elect, Dr. Edward Hamilton, will deliver an address. Notice has been given by Mr. Wheeler, President of the Royal College of Surgeons in Ireland, and by Dr. Jacob, President of the Irish Medical Association, that they will bring the present condition of the Army Medical Department—especially as regards the great block in promotion that exists in the senior ranks of the Department, and the short period

of home service enjoyed by Surgeons-Major—under the notice of the Branch, and will submit a resolution thereon. The annual dinner will be at 7 o'clock p.m., on the same day, in the College Hall.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

PROFESSOR CLELAND ON TERMINAL FORMS OF LIFE.—On the 24th inst., in St. Andrew's Hall, Glasgow, Professor Cleland, of Glasgow University, delivered a lecture "On Terminal Forms of Life," under the auspices of the Glasgow Science Lectures Association. At the outset Professor Cleland showed, from the investigation of organs, textures, development, and date of first appearance of animals, that these all combined to display animal life as a connected and progressive whole. They did not, however, and could not, prove a common ancestry, though certainly they suggested the raising of the question, and the more that observation bridged the gaps between groups far apart, the more possible such community of ancestry would appear. He explained that terminal forms in the animal kingdom, however they might have originated, had no power to advance to a higher level. Examples of these were given in detail from vertebrate and invertebrate forms. Illustrations were taken in the former case from lamp shells, bivalves, star fish, and cuttle fish; while in the case of the latter, it was shown that, although there was an ascending series consisting of fishes, amphibians, reptiles, birds, and mammals, the three last mentioned had all proceeded from animals as low as amphibians, and that each division of reptiles and birds was terminal. Showing by anatomical evidence that the development of the vertebrate form had reached its limit in man, there was no possibility, he said, of doubting that the animals most nearly approaching man were the apes, and that the orang and the gorilla were the highest. So far as the skull was concerned, the orang was decidedly nearer to the human form than the gorilla. Man was a terminus, and not only a terminus, but the terminus of vertebrate life. In defence of this proposition, he asked what had been the whole history of the advance of life from the simplest animals up to man but the growth of structure fitted for the exhibition of consciousness? After referring to the structure of the human body and brain, the lecturer said it seemed in the last degree improbable that in the future there would be a progression in the construction of the human body that would give birth to greater intelligences than the sages and heroes of antiquity.

TERCENTENARY OF EDINBURGH UNIVERSITY.—It has now been decided that the tercentenary of the Edinburgh University will be celebrated on the 16th, 17th, and 18th of April next, and that the proceedings will include a religious service, a graduation ceremony, and a banquet to distinguished guests. Delegates have been invited from the most celebrated universities, colleges, and learned societies in the world.

SIR ANDREW CLARK, M.D., AND THE REPRESENTATION OF CAITHNESS.—A meeting of the Caithness Land Law Reform Association was held in Brim's Hall, Wick, on the 18th inst., Mr. James Waters, Faulds, President, in the chair. It was intimated that the business was to consider what action should be taken in regard to the representations of the county when the seat became vacant. After a

long consultation and discussion, it was resolved to submit the subject of the Association to Sir Andrew Clark, of London, and if he approved of the proposition therein set forth, he was to be invited to address a district meeting of the electors who were members of, or in sympathy with, the said organisation. The Committee, in the meantime, pledge themselves not to ask any other candidate till Sir Andrew had full opportunity afforded him of expressing his political opinions.

SCOTCH VITAL STATISTICS.—From the official weekly returns of the eight principal towns of Scotland for the week ending Saturday, January 13 we learn that the death-rate was 22·4 per 1,000 of estimated population. This rate is 4·9 below that for the corresponding week of last year, and 6·1 below that for the previous week of the present year. The lowest mortality was recorded in Dundee—viz., 15·4 per 1,000; and the highest in Glasgow—viz., 25·9 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3·4 per 1,000, being 6·5 above the rate for last week. Acute diseases of the chest caused 191 deaths, or 4 less than the number for the previous week.

MORTALITY IN GLASGOW.—For the week ending with Saturday, the 19th inst., the death-rate in Glasgow amounted to 25 per 1,000 per annum of the population, as compared with 24 in the previous week, and 39, 25, and 42 in the corresponding periods of 1883, 1882, and 1881.

ABERDEEN.—**TYPHOID FEVER AND DAIRY UTENSILS.**—Dr. Simpson, Aberdeen, Medical Officer of Health for the city, reporting to the Aberdeen Town Council on the epidemic of typhoid fever, now prevalent in the West End, ascribes the outbreak to the washing of dairy utensils in an offensive burn by a milk-seller, whose produce was supplied to the families affected with the disease.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 19th inst., was 89, and the death-rate 19 per 1,000. Diseases of the chest accounted for 40 cases, and zymotic causes for 18, of which 2 were due to fever, 3 to scarlatina, and 5 to measles, the intimations of these diseases for the week being 5, 39, and 165 respectively.

GLASGOW ROYAL INFIRMARY.—The following is the report of the superintendent of this institution for 1883:—During the year the admissions were 5,445; 499 died, which gave the rather high mortality of 9·1 per cent. Of these 140 died within forty-eight hours of admission, and there remained in hospital on 31st December, 1883, 502. The daily average resident was 509, average residence 33·4 days. Non-resident accident cases treated in wards, 1,326; number under fifteen years of age, 878; died 48, or 5·4 per cent. In the out-patient department there were treated at the dispensary—medical, 9,609; surgical, 11,727; treated at dispensary for special diseases—throat, 468; ear, 1,444; women, 337; skin, from 7th November, a new department under the care of Dr. Provan, 68; teeth, 976; vaccinated, 1,532; total treated, 32,682, against 32,687 in 1882; sent to Lenzie Convalescent Home, 584.

GLASGOW EYE INFIRMARY.—The sixtieth annual general meeting of the contributors to the funds of the Glasgow Eye Infirmary was held on the 25th inst., when Mr. James King, of Lovernholm, occupied the chair. From the annual report which was presented, there remained at the close of 1882, 3,608 cases on the books of the Infirmary; the new ones admitted in 1883 were 10,089, making the total number of cases under the care of the medical officers during the twelve months 13,697, being an increase of 490 as compared with the previous year.

If these cases, there were dismissed cured by ordinary treatment, 4,358; cured by operation, 1,484; relieved by ordinary treatment, 1,167; relieved by operation, 169; as incurable, 50; with advice, 2; and as irregular, 10; while there remained on the books of the institution on the 31st of December inst. 2,352. The ordinary income was £2,801 13s. 11½d., and the ordinary expenditure £2,536 0s. 9½d., so that the treasurer had in hand a balance of £15 18s. 2d.

EDINBURGH UNIVERSITY ENDOWMENT ASSOCIATION.—The annual meeting of this Association was held in the Physicist's Hall on Friday last, and was well attended. The report, which was read by the secretary, dealt principally with the funds in hand, and legacies received for the purposes of founding bursaries in the various faculties, and was of a very satisfactory nature. Since the last annual report the following new foundations in the University have been intimated:—£1,500 by Frederic John Mount, M.D., of the Local Government Board, London, and formerly Professor of Medical Jurisprudence in the University of Calcutta, for the foundation of a scholarship to be styled "The Mount Scholarship in Practice of Physics," in connection with the Class of Practice of Physics. The late Miss Dick, of Edinburgh, has bequeathed the moiety of the moiety of her property, estimated to amount to about £10,000, to trustees, under certain conditions, for the purpose of founding a Professorship either of Comparative Anatomy or Surgical Anatomy (whichever the trustees shall consider most desirable in the interests of medical science) in the University of Edinburgh. Sir A. Christie, in moving the resolution relative to the formation of the Stark Scholarship in Clinical Medicine, the amount of which now exceeds £1,463, expressed his entire approval with the conditions imposed by the Senatus:—That the scholarship is to be open to students who are or have been in attendance on the class of Clinical Medicine, and to Bachelors of Medicine of not more than eighteen months' standing who have attended that class; and that the scholar, during his tenure, is to carry on original investigations or other work in the medical wards of the Infirmary, with the approval and under the superintendence of the professors of clinical medicine. Professor T. R. Fraser, in seconding the motion, expressed on behalf of the Medical Faculty, gratification at this generous benefaction. The Marchison Fellowship, which already existed, was competed for every second year, and there was, therefore, an unfortunate gap in the encouragement of the study of clinical medicine produced by the absence of an annual competition. That gap would now be filled. He had no hesitation in saying that research scholarships were the great want of the Faculty of Medicine; and they felt that all the more strongly because of the splendid equipment which the new buildings of the University afforded for original research. This motion was agreed to, and the appointment of office-bearers for the ensuing year terminated the proceedings.

THE DIFFICULTY OF HEALTH REFORMERS.—This formed the subject of the first of two lectures, under the auspices of the Edinburgh Health Society, delivered last week by Mr. H. H. Almond, and, like the preceding lectures, it attracted a numerous auditory. Speaking to his subject, the lecturer remarked that, whenever Hygeia attempted to carry theory into practice, she displayed a combination of qualities which men in general loathed and ridiculed. She was stigmatised as meddlesome, prying, lecturing, and new-fangled, especially in those matters which men regarded as the sphere of custom and common sense, and in which they most prided themselves as being their own masters. The difficulties of hygiene were mainly those of research and discovery. It was not too much to say that if what was already discovered could be realised

in practice, though that day must be far distant, the face of society must be transformed. Why did practice not follow recognised truth in hygiene? The first reason was indifference, bred partly of ignorance, partly of selfishness, and partly of indolence; and the second was the gigantic force of custom or fashion. Sanitary science was advancing by leaps and bounds, so far as it dealt with the surroundings of man; but the wet blanket of indifference was thrown over its most clearly-proved truths when they related to his institutions and habits. Good ventilation was repugnant to those who did not lead wholesome lives. Most of those present were probably too accustomed to rooms habitually over-heated; they were too indifferent about taking exercise; and the custom of having the head covered out of doors and uncovered within doors was too deeply engrained to be within the range of practical reform. He could, however, from his own experience, assert that boys who were usually bareheaded when out of doors could stand a greater amount of ventilation in school-rooms and sleeping-rooms than those who wore head-coverings. He referred to the want of sufficient ventilation in theatres, churches, and schools, and condemned the apathy with which this question was regarded. The knocking down of "rookeries," the opening of new streets, and the widening of old ones had been of great benefit, and for much noble work of that nature Edinburgh could never forget the debt she owed to the memory of her great citizen, Dr. William Chambers.

Literature.

PRACTICAL PATHOLOGY. (a)

THE subdivision of labour advances so rapidly at the present time that students and practitioners become accustomed to the advent of new "manuals."

While for years past the practical aspects of Pathology have been ably demonstrated in the dead-houses attached to our hospitals, as regards the best manner and method of making post-mortem examinations, it is only within recent years, comparatively, that the continuous advances in physiology and pathology have necessitated a like advance in the use, as well as the demonstration, of the methods by means of which the more exact scientific knowledge of the present day enables us to ascertain with precision the pathological importance of morbid anatomy.

Dr. Woodhead has recently published a work on "Practical Pathology" destined to become a classic work of primary value to the pathological student of the future, and replete in pathological precept and practice of value and interest to the scientific practitioner.

The author does not desire to compete in any way with the many already existing and excellent works on pathology; but he has prepared his manual as a "guide to the practical work involved in the study, preparation, and examination of morbid tissues: as an introduction to the study of systematic pathology."

The general features of the work are eminently practical, and the reproduction of the microscopic sections by means of carefully-coloured illustrations amply testify how much time and care must have been expended, both by the author and the publishers, in their execution. A full list of these valuable illustrations follows the preface, including several supplied by the author from original drawings taken in the course of work with the Edinburgh University Practical Pathology Class; while a large number are copied from the best authentic sources, and duly acknowledged. The two first chapters deal respectively with the details of autopsy, based upon Virchow's method of performing post-mortem examinations, and with the subject of practical histology. This latter chapter includes valuable hints on the selection of a microscope, a short résumé of the best methods of using it, and also

a list of apparatus required, as well as of the re-agents in general use by the practical pathologist.

These introductory chapters will commend themselves especially, as worthy of attention, to the student, for upon a thorough mastery of these will depend his fitness to enter upon the study of practical pathology with satisfaction and profit.

The methods of injecting and hardening tissues for microscopic examinations, including the use of "stains," and the practical formulae for their preparation, are all given in detail. The coloured illustrations, already referred to, faithfully express the value which must accrue to the scientific histologist who is first able to demonstrate by the microscope, and then permanently depict by this means the minute structure of morbid tissues. For the student, however, it is possible that the "staining" of tissues rendered pictorially may not be free from error, as he may be led to attach an improper value to the signification of a given "stain," and so become confused. For instance, the "carmine" staining fluid has already been superseded by "logwood" and picro-carmin; "aniline blue black," "osmic acid," "fuchsin," are all employed for investigating the pathology of the nerve centres; while for the differentiation of altered structures "picro-carmin" and "methyl aniline" violet are both valuable. "Chrysoidin" is chiefly used as a contrast colour, but it is gradually being superseded by methylene blue." No doubt these difficulties will be overcome when practical pathologists can concur in attaching a definite differential value to a given "stain," a period which will be as grateful to students and practitioners as to many pathologists themselves.

In discussing the practical pathology of individual organs, the author prefaces each chapter with the normal histology of the organ considered, before he proceeds with the details necessary to determine the various morbid conditions to which each organ is respectively liable.

For the student Dr. Woodhead's work will prove a faithful guide in the study of practical pathology; and as a work of reference, to the practitioner who has time for scientific study, we doubt not this manual will be to him as a walking expert by his side, to which he may apply with confidence, assured that if he follows the instructions given he will be able to produce a reliable section for the microscope. Whoever can conscientiously master the work in all its fulness will prove himself no mean student in pathology, a valuable teacher, and a worthy follower of the author himself.

The conscientious manner in which Dr. Woodhead has placed his knowledge at the disposal of the profession cannot in time fail of grateful recognition; in the meanwhile we can but express a hope that all students of pathology will devote time to study his practical work before proceeding to learn systematic pathology.

THE DISPENSATORY OF THE UNITED STATES OF AMERICA (a).

It is just fifty years since Dr. George B. Wood brought out his Dispensatory which has remained throughout that time the chief book of reference in the United States; passing through fourteen editions and in its jubilee year the fifteenth appeared (1883) adapted to the new American Pharmacopoeia. The book now extends to 1,928 large pages, many of them of quite small type, and includes almost all the drugs used by English speaking people. It has also a number of illustrations, some of these being of microscopic sections of plants. These cannot fail to be welcome. To show the large amount of new matter in this edition, it is only necessary to state that the present index extends to more than 1,600 titles being 5,000 more than its immediate predecessor. Another welcome feature is the indication of the pronunciation of official names. The marks adopted for this purpose are those employed in Worcester's Dictionary. These marks will no doubt tend towards uniformity of pronunciation, and we could wish that they may become generally accept-

(a) "Practical Pathology: a Manual for Students and Practitioners." By G. Sims Woodhead, M.D., F.R.C.P.E. Edinburgh: J. Pentland. 1883.

(a) "The Dispensatory of the United States of America." By Dr. George B. Wood and Dr. Franklin Baehle. Fifteenth edition. Rearranged, thoroughly revised, and largely re-written. By H. C. Wood, M.D., Professor of Materia Medica and Therapeutics in the University of Pennsylvania; Joseph P. Remington, Ph.D., Professor of Theory and Practice of Pharmacy in the Philadelphia College of Pharmacy; and Samuel P. Settlér, Ph.D., F.O.S., Professor of Chemistry in the Philadelphia College of Pharmacy and of General and Organic Chemistry in the University of Pennsylvania, Philadelphia: J. B. Lippincott & Co., 1883.

able and so help to displace some of the absurd differences which have prevailed in pharmaceutical circles.

Those who are accustomed to the use of the Dispensary will find that the present edition is almost if not quite a new book. Nevertheless it is so far founded on its predecessors that they will find no difficulty in referring to any part. The change in the U.S. P. necessitated bringing Parts I and II of former issues into Part I of the present, so that Part III becomes Part II. The enormous advances in Therapeutics are well reflected as we might expect now that Professor H. C. Wood becomes the senior editor. He has also revised the Botany and Materia Medica. The progress of science has rendered it necessary to re-write the whole of the theoretical chemistry contained in this enormous volume, and this part of the work has been conscientiously discharged by Professor Sadtler, who has also revised the toxicology. The labour involved in this department will be appreciated by anyone who compares the fourteenth and fifteenth editions. The Pharmaceutical Department is also largely if not entirely new, and must have entailed great labour on Professor Remington, by whose calculations the official formulae have been adapted to the use of those who prefer to measure liquids. It is stated that the alternative formulae have been carefully tested in practice, and we believe they will be found very useful. At any rate during what may be called the transition stage caused by the plan of ordering parts by weight adopted by the new U.S. P.

The editors tell us that the work has occupied most of their spare time during the last three years, and we can well believe this for the more we examine it, the more we admire its extent and accuracy. We do not pretend to have read it straight through, indeed such a proceeding would not be expected from any critic; we have, however, employed it as a book of reference since it has come into our possession, and being actively engaged in some departments upon which it treats and specially interested in others, we were gratified with the result on every occasion on which we have turned to it. Sometimes we have tested it on points which we thought likely to be overlooked or insufficiently treated, but found it in every instance quite up to date, and with scarcely any deficiencies worth recording. We have, therefore, no hesitation in recommending this valuable but bulky volume as a most complete and reliable encyclopedia.

Novelties.

ALLEN AND HANBURY'S MALT JELLY.

Messrs. ALLEN & HANBURY have supplied us with samples of a new malt preparation in the form of jelly. This constitutes a most palatable and refreshing article of food, which invalids will certainly appreciate at the highest. The jelly is bright, clear, and firm, and is variously flavoured with malaga, vanilla, &c. As an invigorating and strengthening adjuvant, malt jelly possesses admirable qualities; and to nursing women it offers especial advantages. We have found it highly serviceable to such patients, and even infants have been given the jelly dissolved in water with no result other than the appearance of rapid growth. Messrs. Allen and Hanbury may be congratulated on producing so successful a preparation, the value of which, both therapeutically and dietetically, is beyond question.

SCOTT'S COD-LIVER OIL EMULSION.

THE difficulty of so disguising the taste of cod-liver oil as to make it palatable to invalids and children has long stimulated the ingenuity of pharmacists to devise a mode of preparing it so that the distinctive taste should be lost. Some of these are more successful than others, but the preparation before us which we have tested in actual practice possesses all the advantages claimed for it, and we are glad to note that it is gaining ground in this country as a safe and efficient remedy. This emulsion, which is of American origin, is made by Messrs. Scott and Bowne, New York, the English agents being Messrs. Newbery and Sons. Pure cod-liver oil exists in it to the amount of 50 per cent., while each fluid ounce of the emulsion contains six grains of hypophosphite of lime and three grains of the same salt of soda, the tissue-stimulating properties of the mixture being thus incalculably increased. Moreover, it is almost pleasant to take, and possesses none of the objectionable qualities of oil by itself.

HINTONS PLASTER OF PARIS BANDAGE MACHINE.

THIS invention of Mr. Hinton's is for the purpose of impregnating bandages with dry plaster of Paris, and rolling them at the same time, and is a very much cleaner method than at present employed, namely, rolling them by hand: beside the plaster of Paris is more evenly spread in the meshes of the bandage. This machine consists of a suitable

framework, on which is mounted a box, or hopper, for containing the plaster of Paris. At the bottom of the hopper there is an elongated slit, within this is placed a fluted roller. On the end of the spindle on which the roller is placed there is a pulley mounted, driven by means of a belt or strap from another pulley mounted on the end of a horizontal shaft of small diameter, supported by the framework, and provided with a crank arm, or handle, on which the bandage is wound. The bandage to be impregnated with the dry plaster of Paris is passed under the machine, and brought round the roller at the back of the hopper, then passes under the hopper, and a stretcher which is placed there for the purpose of spreading the plaster evenly in the meshes of the bandage. The bandage is rolled up whilst the plaster is being incorporated with it, just in the same manner as it is wound up by an ordinary bandage machine. The bandage after being rolled is removed, and only requires soaking in water a few minutes when it is ready for use, or a number can be made at once, and placed in a dry tin, and kept for use when required. By this machine the plaster is more equally distributed in the bandage, and the bandages are more easily made. It has been used largely at the Royal Albert Edward Infirmary, Wigan, and it is found to answer the purpose for which it is intended. Mr. Hilton will be glad to supply the machine, or furnish testimonials and particulars respecting it, if communications are addressed to him at the above Infirmary at Wigan.

CHRISTY'S PINE EXTRACT.

THE healthful properties of pine preparations are so well known that every addition to the number of articles containing pine products is sure of receiving welcome. Mr. Christy, F.C.S., of Fenchurch Street, has, however, made a pine extract for adding to baths, and for general antiseptic use, which deserves especial recommendation on account of its pleasant and agreeable characters, and its efficiency. It is put up in bottles, and can very easily be added to the water used for bathing or cleaning, imparting to it a refreshing odour, and giving it decided antiseptic qualities.

CAFE VIERGE.

THE wholesome stimulation of coffee is so well appreciated by lovers of the beverage that any method of preparation which simplifies its production for drinking purposes, and at the same time preserves its essential properties will be eagerly welcomed by them. Messrs. Allen and Hanbury, in conjunction with Messrs. Ridgway, the well-known coffee growers, have succeeded in producing an essence of coffee which is absolutely perfect, which possesses every attribute of the berry, and which is so put up as to be at once available with the addition of water or milk, to form a most palatable and delicious cup of coffee. When made with boiling milk, moreover, it is an efficient and nutritious food, and will be readily taken by the most fastidious stomach. The preparation is sold as "Café Vierge," and is the only extract of coffee we have examined, which is absolutely free from adulteration.

WHEELER'S PIXENE.

ANTISEPTIC toilet preparations require to be pleasant alike in appearance and to use, in order to be acceptable, and it is probably because many of those advertised do not answer these conditions that they fail to find favour. The "Pixene" prepared by Mr. Wheeler, of Ilfracombe, is a non-poisonous product of pitch tar, made by a special process, and possessing valuable properties as an antiseptic. There is also a pixene soap, possessing the qualities of the liquid; it is a very pleasant toilet requisite.

Correspondence.

THE CONJOINT EXAMINATION SCHEME.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the *Medical Press and Circular* of January 16th, 1884, page 59, the following inaccurate statement appears:—

"These candidates, if they accepted the Irish conjoint diploma, would be expressly forbidden by the by-laws of the College of Physicians to engage directly or indirectly in the sale of medicines, and would be required to make declaration that they would surrender their diploma if they violated this regulation. As a fact, a Licentiate of the College was recently struck off its list and deprived of his diploma for having sold medicines; and, as a further fact, Irish students entering general practice in England might be required to surrender their diplomas the moment it was discovered that they made a profit by supplying medicines to their patients."

I enclose a copy of the Regulations relating to the licences of this College, containing (on page 12) the declaration taken by Licentiates in Medicine. In that declaration the passage relating to the sale of medicines is as follows:—"And I consent to surrender the diploma received from the College if I shall, after having obtained the licence of said College, keep open shop for the sale of medicines."

As a matter of fact, the Licentiates of this College are not debarred from dispensing medicines to their patients, and the Licentiate referred to in your editorial remarks surrendered his diploma because he violated the terms of the declaration—not by having sold medicines, but by keeping open shop for the sale of medicines.

You will much oblige me by inserting this correction in the next issue of the *Medical Press and Circular*.

I am, yours, &c.,

J. W. MOORE, M.D. Dub.,

Fellow and Registrar.

King and Queen's College of Physicians
in Ireland,

Dublin, Jan. 26th, 1884.

[Our statement was made with special reference to the fact that, if the College of Surgeons bound itself to a compulsory double diploma scheme in conjunction with the College of Physicians it must necessarily lose the patronage of the Irish apothecary. This is quite true in every case in which the L.A.H. or the general practitioner wishes to have liberty to make up prescriptions for others than his own patients, as he would thereby come within the category of those who keep "open shop."—ED.]

Royal College of Surgeons of England.—The following candidates, having passed the necessary examination for the diploma, were admitted Members of the College on Monday, January 21st:—

Anderson, F. Uniacke, L.R.C.P. Edin., Halifax, Nova Scotia.
Bell, John, L.R.C.P. Lond., Albert Street, London.
Bradshaw, Thomas Robert, M.B. Dub., Amphil Square.
Edwards, William Lloyd, L.R.C.P. Lond., Carmarthen.
Harris, C. J. Joseph, L.S.A., Wandsworth Common.
Harris, John William, L.S.A., Ivybridge, Devon.
Hoffmeister, George Bernard, Furnival's Inn.
Kirby, Ernest Doraer, M.B. Edin., Leamington.
Kite, E. W. Dawson, L.S.A., West Bromwich.
Ley, Henry James, M.B. Edin., Teignmouth.
Mackay, Norman Eben, M.D., Halifax, Nova Scotia.
Minter, Ernest Denman, L.R.C.P. Edin., Plympton, Devon.
Myles, George Thomas, L.R.C.P. Edin., Bristol.
Fraser, J. Joseph, L.R.C.P. Edin., Melbourne, Australia.

Ridley, George Walter, M.B. Durham, Newcastle-on-Tyne.
Sheppard, Henry Anderson, L.S.A., Southampton.
Scott, Arthur William, L.S.A., Stourbridge.
Webster, Trevor, L.S.A., Bewdley.
Williams, George Herbert, L.R.C.P. Edin., Warrington.
Young, Charles Stewart, L.S.A., Dundee.

The following were admitted on Tuesday, January 22nd:—

Aitken, William Blair, M.B. Glas., Daley, N.B.
Bean, William Henry, L.S.A., West Mersa, Essex.
Buxton, William Maberly, M.B. Durh., Alderney Road.
Francis, William Henry, M.B. Edin., Coquimbó, Chili.
Jackson, Allan Heslop, L.R.C.P. Edin., Holtham Road.
Jefferson, Robert Pickering, Leeds.
Kendall, Arthur Samuel, M.D. New York, Sydney, Nova Scotia.
Lawrence, Lauric Asher, L.S.A., Belsize Avenue.
Parsons, John Inlis, M.B. Durh., Blackheath.
Scott, John, Barnard's Inn.
Spicer, Frederick, M.B. Durh., Carleton Road.
Tyler, Herbert Paget, Barnard's Inn.

The following were admitted on Wednesday, Jan. 23rd:—

Bradbrook, William, L.S.A., Green Street, London.
Hunt, Bertram, Oxford.
Kebbell, Charles, Brighton.
Koettlitz, Reginald, Dover.
Lanckester, Alfred Owen, Belsize Park.
Saunders, James Frederick, L.S.A., Gravesend.
Sheldrake, Edward Nodin, L.R.C.P. Edin., Albion Street.
Tilley, William James, L.R.C.P. Lond., Shepherd's Bush.
Wenyon, Edwin James, M.B. Lond., Coniscliffe, Darlington.
Weller, Charles Joseph, L.R.C.P. Lond., Colehill Street.

The following were admitted on Thursday, January 24th:—

Adams, Charles Edmund, Carno, South Wales.
Carter, Arthur Joseph, Harleyford Road.
Crowle, T. H. R., Campden Hill Road.
Davis, W. P., Kbury Street, S.W.
Fuller, G. H. H., New Shoreham.
Gooding, M. R., L.R.C.P. Lond., Oakley Square.
Harvey, James, Leicester.
Hughes, E. A., Bentinck Street.
Johnson, G. H., Wath-on-Dearne.
McDonnell, W. C., L.R.C.P. Lond., Stoke Newington.
Power, E. T., Denmark Hill.
Robt, C. E., Powys Square.
Spicer, W. T. B., Saffron Walden.
Styan, T. G., Eastbourne Terrace, W.

The following were admitted on Friday, the 25th:—

Barrett, J. W., M.B. Melbourne, Melbourne, Australia.
Carroll, E. R. W. C., Workingham.
Dill, J. F. G., M.B. Cantab, Lower Belgrave Street.
Edin, Herbert E., Manchester.
Edwards, David G., Denbigh.
Eleyatamby Mudaltamby, L.R.C.P. Edin., Colombo, Ceylon.
Hawkins, G. C., Teignmouth.
Rogers, W. F. C., Falmouth.
Ross, Elsie F., L.R.C.P. Lond., Sydney, New South Wales.
Taylor, Robert, Mendlesham, Suffolk.
Thomas, A. W., L.S.A., Clapham Common.
Wale, George, Carshalton.
Webb, Hugh, Buckingham Palace Road.

The following were admitted on Monday, the 28th:—

Bird, Henry, L.S.A., Bampton.
Carnelley, Matthew, Fallowfield.
Evans, C. E., Bristol.
Goetling, I. H., Halesworth, Suffolk.
Grower, William, Brentwood.
Habgood, William, L.S.A., Wimborne.
Hudson, C. L., L.S.A., Bungay.
Lewis, J. L., L.S.A., Llandoverly.
Lilley, J. H., M.B. Cantab, Atherton.
Marriner, W. H. L., L.S.A., Gunterstone Road.
Pilgrim, H. W., L.S.A., St. Augustine's Road.
Samut, R. P., L.S.A., Malta.
Townsend, E. B., L.R.C.P. Edin., Colchester Street, S.W.
Vince, J. F., L.S.A., Birmingham.
Warner, F. A., Kensington.
Wholey, Thomas, L.R.C.P. Lond., Gainsborough.
Woolby, J. B., L.R.C.P. Lond., Halesworth, Suffolk.

Odontological Society of Great Britain.—At the annual general meeting of this Society, which took place on the 14th inst., the following Members were elected as Officers and Councillors for the year 1884:—President: James Smith Turner. Vice-Presidents: George Gregson, Henry Moon, T. Charters White, Wm. Doherty (Dublin), J. T. Browne-Mason (Exeter), and Richard White (Norwich). Treasurer: James Parkinson. Librarian: Felix Weiss. Curator: S. J. Hutchinson. Editor of the Transactions: Henry Sewill. Honorary Secretaries: J. H. Mummery (Council), David Hepburn (Society), Robert Woodhouse (for foreign correspondence). Councillors (Resident): Geo. A. Ibbetson, Ashley Gibbings, Thos. A. Rogers, Chas. S. Tomes, Wm. St. George Elliott, Augustus Winterbottom, F. Canton, Alex. Cartwright, Storer Bennett; Provincial Members: R. Rogers (Cheltenham), W. Hele (Carlisle), J. F. Cole (Ipswich), G. C. McAdam (Hereford), W. E. Harding (Shrewsbury), A. Wilson (Edinburgh).

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 stories for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

MR. KILNER.—The gentleman referred to has retired from the active practice of his profession, though his name is used by his successor as "an attraction."

W. P. O. L. (Charleville).—The best and most reliable treatise in the French language on medical jurisprudence is that by Briand et Chaudet, entitled "Manuel Complet de Médecine Légale." Legal chemistry is also included in this work, which is published in two vols. by MM. Ballière et Cie, price 24 francs.

MR. SALMON.—Charpentier's "Traité pratique des Accouchements" is the latest and certainly the most exhaustive work on the subject with which we are acquainted. It was published about the middle of 1883.

MR. GREENWOOD.—Nitro-glycerine in solution is reputed to be almost specific in relieving the agonising pain of angina pectoris. It is administered in one-hundredth of a drop doses, and acts on the vaso-motor system.

THE ORIGIN OF THE WORD "CHARLATAN."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—The ingenious story in your last issue respecting the origin of the word charlatan is so "well found" that it is a pity it should not be "true." But Brachet, in his Etymological Dictionary, gives the word as having been introduced (with a host of others) from Italian into French in the 16th century. From the verb *charlatre*, to prate, to chatter, come both *charlatore*, a chatter-box, and *charlatano*, a quack, as well as *charlataner*, which signifies both loquacity and quackery. The connection of ideas is evident, as it is also that charlatan meant originally, not "a driving doctor," but "a talking doctor."

Yours, &c.,

BEN TROVATO.

January 21st, 1884.

DR. DRUMLEY.—There is not, as far as we can ascertain, any ground for the suspicions you have entertained. The regulations of the Board are precise, and do not admit of being contravened with impunity. Your informant is probably in error.

F. L. E.—Such a proceeding on the part of a hospital supported by public contributions would be regarded as an infringement of the rights of the poor, which are protected by the assistance of the donors to the charity.

THE SWINEY PRIZE.

THIS prize, which consists of a silver goblet, value £100, containing gold coin to the same amount, and which is presented every fifth anniversary of Dr. Swiney's death to the author of the best published work on Medical Jurisprudence, has been awarded by the College of Physicians and the Society of Arts, the adjudicators under the will, to Professor Sheldon Amos, M.A. for his work entitled "A Systematic View of the Science of Jurisprudence." The cup has been executed by Messrs. Garrard, from a design made expressly for the Society by the late Mr. MacIise, R.A.

DR. GOYDER (Bradford) is thanked for his note.

G. S. C. (Liverpool).—Our correspondent is referred to our "Reports and Analyses on the Mineral Waters of Europe" for an answer to his queries. These Reports are now reprinted in book form, and constitute the most reliable data on the composition and therapeutic value of every known bottled water issued in modern times.

MR. F. O. R. (Knutstorf).—Communication received; shall have early attention.

MR. S. (Edinburgh).—We have searched the Medical Register and the Directory, but fail to find the name of the gentleman referred to. You may, therefore, consider your suspicions confirmed.

A. H. F.—An amputation performed less than thirty hours after the accident necessitating it occurred would be a primary operation, and the chances of recovery less favourable. We cannot undertake to make the suggestions until assured that the circumstances warrant such a proceeding.

DR. FRARSON.—Please accept our best thanks for the enclosures, none of which had previously come under notice. The number of cases mentioned in the report is exceedingly large, but it has been ascertained that even this extensive list does not include all the instances it might.

THOMAS ON FRACTURES OF THE NECK OF THE FEMUR.

In the excellent paper which appeared in our last issue, from the pen of Mr. Hugh Owen Thomas, of Liverpool, there is a slight clerical error, which materially alters the meaning the author intended to convey. At page 66, paragraph 4 reads: "The evils which our past and present practice up to this time has failed to avoid are these: The patient might after treatment be enabled to extend his leg properly, or, when standing, to maintain his thigh rigidly in a line with the leg,

&c." The word *enabled* should here run *unable*. Our author wishes also to make the following correction at page 66, line 7:—"Shortening" should read "apparent shortening."

MR. FRENCH.—It would be well, before finally deciding which school to select, to make yourself personally acquainted with the arrangements at more than one. All are not equally well adapted for the prosecution of such special work as you propose to engage in, and some are specially likely to suit your wishes in this respect. The editor of the *Students' Journal* will be able to give you the information necessary to guide you in this.

M. J. R.—There was but one objection raised so far as we know, but it was all-sufficient, being none less than that death had solved the problem, and thus settled the difficulty.

ARTHRITIS.—Not always of old age, but in the great majority of cases. The sensation conveyed to the fingers on feeling the artery is unmistakable, and once experienced, no difficulty will afterwards be found in diagnosing a similar case. Treatment must be of a careful description, and the state of the vessels be constantly borne well in mind.

DR. REYNOLDS.—It shall be done.

Meetings of the Societies.

THURSDAY, JANUARY 31ST.

THE PARKS MUSEUM OF HYGIENE.—At 5 p.m., Mr. H. A. Darbishire, On Artisans and Labourers' Dwellings.

FRIDAY, FEBRUARY 1ST.

CHARING CROSS HOSPITAL MEDICAL SOCIETY.—At 8 p.m., Mr. F. A. Saw, On Homoeopathy.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At 8 p.m., Mr. Keetley will show cases of (1) Hey's Amputation; (2) Piragoff's Amputation (two cases); (3) Syme's Amputation; (4) Amputation through Knee-joint, Patella being left.—Dr. J. Allden Owles, On the Progress and End of a Case of Aphasia.

SATURDAY, FEBRUARY 2ND.

ROYAL INSTITUTION.—At 3 p.m., Professor Morley, On Life and Literature under Charles I.

MONDAY, FEBRUARY 4TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At 8 p.m., the President, Mr. J. S. Turner, will deliver his Introductory Address; after which Casual Communications by Mr. G. W. Parkinson, Mr. F. Canton, and Dr. W. St. George Elliott.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Parker will commence a course of lectures on Mammalian Descent.

ROYAL INSTITUTION.—At 5 p.m., General Monthly Meeting.

WEDNESDAY, FEBRUARY 6TH

LONDON HOSPITAL.—At 2.45 p.m., Emeritus Professor Jonathan Hutchinson will commence a course of Six Lectures, the first being On Natural Groups of Skin Diseases.

Vacancies.

Ardee Union, Dunleer Dispensary District.—Medical Officer. Salary, £120, and £25 as Medical Officer of Health. Election, Feb. 4.
Sussex County Hospital.—Physician and Assistant Physician (Honorary). Applications to the Secretary by February 6.
West Herts Infirmary, Hemel Hempstead.—House Surgeon and Dispenser. Salary, £100, with board, &c. Applications to the Secretary by February 6.
Wolverhampton and Staffordshire General Hospital, Wolverhampton. House Physician. Salary, £100, with board, &c. Applications to the Chairman of the Medical Committee, on or before Feb. 8th.

Appointments.

CARTER, R. C., L.R.C.S.I., Apothecary to Nass Union Workhouse.
CLARKE, J. P., M.D., Medical Officer to Castleblayney Almshouse.
FISHER, S. W., M.D., Physician to the Brighton and Hove Dispensary.
LIMONT, J., M.A., B.Sc., M.B., House-Physician to the Infirmary, Newcastle-on-Tyne.
REYNOLDS, J. J., L.R.C.P.L., M.R.C.S., Medical Officer for the Boxford District of the Conford Union.
ROE, A. D., B.A., M.B. Cantab., M.R.C.S., Clinical Assistant to the Brompton Hospital for Consumption.
SMYTH, F. S., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the Brockley District of the Royal Kent Dispensary.

Births.

MILLER.—January 24, at Horwoods, Basingstoke, the wife of F. D. Miller, L.R.C.P. Lond., of a daughter.

Deaths.

BARKER.—January 21, at 82 New Cross Road, Hatcham Park, S.E., Robert Barker, M.R.C.S., L.R.C.P., aged 44.
FOOTE.—January 24, at his residence, Kingston, Herefordshire, Gustavus Foote, M.R.C.S. Eng., aged 59.
FORTESQUE.—Jan. 15th, at Albert Road, South Norwood, W. Fortesque, F.R.C.S., late of Charterhouse Square, aged 70.
WEDDELL.—January 25, at Hornsey Rise, London, Jane, wife of W. H. Weddell, M.R.C.S. Eng.
WILSON.—January 24, at Llancoonant, after a short illness, George Wilson, L.R.C.P.E., formerly of Lowick, aged 52.

NEPHRITIS ARTHRITICA. (a)

By RUDOLPH VIRCHOW, M.D.,
Professor of Pathological Anatomy in the University of Berlin.

If one seeks in literature for the history of the changes that take place in the kidneys and urinary organs in gout one will find very little satisfaction, for the reason that the relations are somewhat mixed up. It is especially confusing that the question of uric acid concretions, which are met with in the form of gravel, renal or vesical calculi, has been introduced into the subject, and concerning which the opinion for a long time has been constantly cropping up that they have some close relationship to gout. My experiences, which on this subject have been principally of an anatomical nature, have not led me to recognise this relationship. So far as uric acid vesical calculi are concerned the number of cases in which they are met with in undoubted association with gout is very insignificant. In the majority of the calculi no gouty connection can be verified. In regard to concretions in the pelvis of the kidney and in the calices it is not proved that any considerable deposits have any connection with gouty conditions, and inversely it cannot be said that a gouty patient is in any danger of acquiring such deposits. Should, however, such a connection exist, one should not exclude the fact that only a small number of concretionary formations coincide with ostensible cases of gout. In regard to the manifestations of gout, I would remark upon one circumstance that has not received sufficient attention in literature, namely, upon the relative frequency of forms of gout in which the usual paroxysmal attacks have not occurred. I was first led to notice such cases by the circumstance that not unfrequently, on the dissecting table the most varied changes were present in persons concerning whom no

suspensions of gout had existed in the minds of the medical attendants. During the years in which I had a department of the Charité I saw a not inconsiderable number of cases of gout during life, in whom evidences of the disease came to light as very striking, more or less anatomical phenomena, without paroxysms even having been observed in them. I caused some cases of this kind to be made the subject of a dissertation in 1868 by Hartmann. In these cases the various parts of the body affected were painful, it is true, but the condition showed no kind of paroxysmal onset, and did not correspond in any way to what is generally designated joint-affection, podagra, &c. Examination of the various conditions everywhere showed that the mass of these tophi was composed of a pultaceous mortar-like substance, which, examined under the microscope, was found to consist of urate of soda. In regard to terminology I would remark here that the old name tophus arthriticus is perfectly justified. In this mortar-like mass lies the difference that separates this form from all the other forms of nodes and exostoses that consist of actual bone substance and are organised formations. These characteristic deposits, which consist of urate of soda, have never yet with absolute certainty been met with in the human body without at least a suspicion arising that we are dealing with a case of gout, and generally the suspicion can be proved correct. In the meantime, we must necessarily discriminate between the paroxysmal course of gout and the chronic, latent course in which no paroxysms appear, but changes gradually take place which are frequently greater than those we meet with in paroxysmal gout.

Up to a certain point it may be possible that this division corresponds to that of rich man's gout and poor man's gout (*arthritis divitum* and *arthritis pauperum*) a division that people have attempted so to define in another way, that *arthritis pauperum* has been made synonymous with *arthritis deformans*, which gives rise to spontaneous bony out-growths. In my opinion, however, we must distinguish in the chronic form between

(a) An address delivered before the Berlin Medical Society, Dec. 19, 1883.

the ordinary *arthritis deformans* and the specific uric acid arthritis, and sharply separate the one from the other, for after the most careful observation I have only been able to verify in a joint the simultaneous appearance of both kinds, i.e., growth of bony structure and deposit of uric acid salts in a single instance. If it is wished to bring these processes into a kind of theory, one can, without doing violence to facts, so represent them that the forms that are ushered in by violent attacks occur in persons in whom a large material of nitrogenous substances is awaiting the disintegrating processes within the body, and as the opinion is a ruling one that gout stands in some relationship to excessive indulgence in the pleasures of the table, and immoderate consumption of nitrogenous foods, it may be thought that the violent course and the stormy manifestations are dependant on increased supply of albuminates, whilst in the case of poor people it stops short of violent eruptive appearances and takes on a more chronic course. From my earlier observations on the living I have reached the conviction that the theory that makes gout principally dependant on a luxurious consumption of albuminates is erroneous, for I have met with it in prisoners who had lived for years in the most miserable circumstances. The peculiar disposition of the body then that is the cause of this increased production of albuminates is in no way dependant on the richness of the supply, but there must be some other condition at work concerning which I am not in a position to speak. If, in the mean time, it is assumed that a certain disposition is present, it must, at the same time, be confessed that it can be operative also under conditions of want and poverty, in which the quantity of albuminates never takes on the character of luxury or of excess.

Now, as regards the kidney in connection with these conditions, we have this special peculiarity—that the salts are deposited in the substance of the kidney, and, in fact, in the urinary tubules. When Ebstein defended the opinion that such deposits were present in the interstitial tissues of the kidney, I remarked in opposition to him that I had never seen this. The deposits in the urinary canals are really found in the pyramidal substance.

On section you will often see, even with the naked eye, in the centre of a pyramid some strikingly white streaks, which sometimes seem to be so thick that to some extent you are able to recognise the granular matters, and so large that you can raise them up with the point of the scalpel. Under the microscope it is seen that they do not form fine acicular deposits, but tolerably large rhombic columns. They are quite colourless, and considerable numbers are generally united together to form such a small plug. By careful section through the substance you can easily convince yourself that these bodies lie in dilated parts of the tubules. When this condition is met with the joints are always examined, and with surprising frequency a great number of places are found in which the joints also exhibit these deposits.

In regard to these conditions, the question arises whether such proof of the presence of crystalline plugs is sufficient to prove that the individual has suffered from arthritis. In this respect I agree that my data are to a certain extent defective, owing to a limited employment of the anatomical material at my disposal, but I have ascertained that some cases occur in which I have not succeeded in discovering in their usual sites—in the knee-joint, for example—any such deposits, in which the plugs in the kidneys alone had given rise to the suspicion of gout. These cases, however, are so scattered that I cannot resign the thought that there may still have been parts of the body in which such deposits were present. Perhaps, also, there may be arthritis without the joints being affected. This view has nothing self-contradictory in it; for if we are compelled to look upon gout as a process in which large quantities of urate of

soda are formed which are first found in the blood, it cannot be a question for dispute that under certain circumstances the greater part of it may be excreted, and only occasionally one or another deposit in the kidneys testifies that such a series of processes has taken place. I freely acknowledge the deficiency of these proofs, but there is at present no other condition known capable of accounting for these constitutional changes.

If we examine more thoroughly the kidneys in which such deposits have taken place, we perceive that further structural changes have taken place, most of them referable to chronic interstitial nephritis. They are not by any means found in the same localities as the deposits, but far more on the surface of the kidney, and they dip down into the cortical substance. You see depressions with small cicatrix-like processes originating, whilst in the interspaces the kidney parenchyma may be quite intact. In itself the knowledge of such a kidney is of no small interest, for the reason that, as is known, such a cicatrix-forming nephritis is not unfrequent, but we only know with certainty of two other affections in which it takes place—(1) the endocarditic, and (2) the syphilitic form. In the cicatrices themselves there is nothing that affords proof that they have any connection with arthritis, and the association of the cicatrices with the deposits is the first thing that affords a justification of the view that the process is arthritic. As the processes are multiplied, diminution in the size of the kidney at last takes place—an atrophy that only differs from the granular form by exhibiting a coarser limitation. The cortex is now no longer the part affected, the processes strike deeper, the whole substance atrophies, and microscopically you find a large number of glomeruli in process of destruction, and having capsular processes; the final result is a tolerably high degree of renal atrophy. I will not deny that under such circumstances a parenchymatous nephritis may come on that is analogous to the infectious form. I have seen a quite acute form of this kind which was in direct connection with arthritis, but I am aware from reading and from my own observations on the living that albuminuria occasionally occurs along with arthritis. I would make the statement provisionally that there is an arthritic nephritis without arthritis, and without the other manifestations of it.

In discussing the question what the element may be that gives rise to the inflammation; although the one process is mainly met with in the cortex, and the other in the canals of the pyramidal substance, we should not conclude that the uric acid crystals are the irritative element that sets up the inflammatory processes. We can assume that the *materies* causes the separation of the uric acid salts, and that these excite the inflammation. But it is to be pointed out that the localities in which the processes play this part are varied. In every arthritic joint the deposits of uric acid salts are principally formed on the cartilage and on the ligamentous apparatus around the joint, i.e., in the extravascular parts, they moreover penetrate within these, and do not form a simply external deposit. But these are not the parts in which the inflammation originates, it is the synovial membrane in which it commences. If we examine a joint in an early stage of an attack, we find great redness of the synovial membrane with some degree of purulency, but no urate of soda. I believe it is not the completely separated solid crystallised urate of soda, but rather the still dissolved fluid, that is, the *materies* that gives rise to the inflammation. Then one can only conceive the process as taking place in the kidneys. Not those localities that contain crystals are the seat of the nephritis, but it develops outside of them. That the irritant resides in the peculiar property of the excretions, however, I am fully convinced, and I am strengthened in my conviction by my own illness of last year. I have never in my life had an attack of gout, but have occasionally had a slight painful puffiness, but never diminished power of move-

ment of the joint. During the course of last year an irritation of the bladder first came on, with a good deal of urgent desire to micturate, and occasionally burning pain along the ureters. The urethral orifice became red, but I did not consider this of much importance. When, a year ago, I had a severe attack, the result of external causes, after the pyrexia had passed away, a very violent irritation of the urinary organs came on, which was associated with a great deal of purulent discharge, but without sediment, so that what was passed looked like pure pus. I had at the same time urgent desire to micturate, and great pain during the act. The medical attendants exhausted themselves in conjectures as to the cause. One day after I had passed a small purulent mass, I began to examine it microscopically, and found nothing but round cells with great power of movement. I accidentally added a little vinegar, and was surprised to find the whole field of vision suddenly covered with crystals of uric acid. My first thought was that an energetic alkali was required, and I at once took a strong dose of borate of soda, and from the next morning I passed no more pus nor produced cylinders. From this, I think, I must draw the conclusion, that the great over-loading of the system with uric acid salts in solution, had produced a strong irritation, and finally a purulent catarrh of a most violent form.

In regard to diagnosis there are conditions in the kidneys in which, in like manner, bodies like those described are met with. There is the condition in which lime is deposited in the kidney. In the calcareous kidneys the lime is indeed always found in the excretory passages, but there is a certain difference between them. The most frequent form is that in which thick white points are met with at the apices of the papillæ, which often pass on into a grumous mass. This condition is found in calcification of the *tunica propria*. Such a tubule has its lumen patent, but it has no epithelium. The cause of the calcification lies in denudation—the epithelium is dissolved in the catarrhal process, and expelled with the urine. In the second form the lime lies within the tubules. This condition is frequently met with in the cortical substance, very frequently in the capsules of the glomeruli, so that these under backward pressure of the glomerulus become more and more filled with calcareous salts, in such a way that one can see these white patches on the surface of the kidney. This form not unfrequently exists in connection with chronic nephritis, like that with arthritis which is only distinguished by the greater disposition to form small cysts. The urinary tubules form varicose bodies which shut themselves off from the rest of the tubule and thus form cysts.

A Course of Lectures

ON

THE EYE: ITS DISEASES, AND THEIR REMEDIES.

Being an Abstract of a Course of Lectures delivered in the
Royal College of Surgeons in Ireland,

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
Professor of Ophthalmic and Aural Surgery in the College;
Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 87.)

Tumours of the Conjunctiva.

THE conjunctiva is liable to the inroad of a variety of tumours—viz, epithelial, melanotic, and medullary growths, warts, fatty and dermoid tumours, polypi, and cysts. It is also subject occasionally to syphilitic ulceration. I do not propose to deal at length with these growths, the diagnosis and treatment of which is to be decided, not by rule, but by the exigencies of each particular case. The

benign growths and those which have not extended beneath the conjunctiva are easily excised. The cancerous and other extensive growths will probably involve the removal of the entire eyeball or even of the contents of the orbit.

Pterygium. So called from its resemblance in shape to a fly's wing (*πτερον*)—is a hypertrophy of the conjunctiva and subconjunctival tissue, occurring usually as a sequela of long-continued conjunctival irritation and granulation. It is classified by authors into *Pterygium tenue*—*P. crassum* and *P. pingue*, according to the thickness of the growth and the development of fat in its structure. It usually presents itself as a thin (*tenue*) triangular web of thickened conjunctiva, with one or two veins on its surface, the base of the triangle being spread out at either canthus, and the apex at the corneal margin. Sometimes

Fig. 11. Pterygium Tenue (MACKENZIE).

it encroaches upon the cornea even as far as the apex, and causes dimness of sight. It is usually not adherent to the sclerotic, but when it is of the denser variety (*crassum*), it sometimes becomes attached, and may form an impediment to the motion of the eye. Occasionally the fat cells are largely developed within and under the growth (*pingue*), and it presents a very visibly opaque tumour on the conjunctival surface. In any case it is extremely slow of growth, and takes years to become fully developed, but if left to itself it often encroaches on the cornea and interferes with sight.

The treatment of Pterygium usually consists in its removal by operation. In the earlier stages, while it is still quite thin, it may, if confined to the conjunctiva, be got rid of by burning it superficially with nitrate of silver or perchloride of iron, and by astringent applications; but these means are not applicable where it extends over the cornea, and they are insufficient when the growth becomes strong and dense. The methods of removal are—1. Excision; 2. Ligature. To excise it, the patient must be anaesthetised, and the lids divaricated with the spring speculum. The growth, being seized in its entire width by the forceps, should be raised as far as possible from the eyeball and dissected off, beginning at the apex. It

Fig. 12. Excision of the Pterygium (STELLWAG).

is not quite easy to remove the whole of it from the cornea without injuring the subjacent surface, and in any case a slight opacity will be left, because of the close connection between the growth and the cornea. The dissec-

C

tion may be made with sharp-pointed scissors or cataract-knife. I prefer the latter, and it should include the entire growth, as far as a quarter of an inch from the cornea, where the base of the incision should be finished off, not by a straight cut across the base of the triangle, but by converging the edges of the incision to a point. The object of this is that the base of the triangle may not be puckered when the conjunctival edges are brought together with sutures, which procedure is necessary to complete the operation. If the conjunctival edges are neatly sutured, no risk of the recurrence of the pterygium will arise.

The ligature of the pterygium is to be preferred to excision whenever it seems that the growth is closely adherent to the cornea, and that injury may arise from the dissection. The annexed illustration shows the

Fig. 13. Ligature of the Pterygium (STELLWAG).

method. Two needles being armed with the two ends of one ligature, having been introduced under the pterygium at its two extremities, the needles are cut off, the ends of the outer portion tied, then those of the inner portion, and, lastly, the two ends of the central ligature which appear below the pterygium; the ends are nipped off and the lids closed, and the pterygium, thus strangulated, sloughs away, and never recurs.

It has also been proposed to transplant the pterygium by dissecting it up to its base, as in the excision operation, and passing it into a pocket made in the conjunctiva, where it is to be sutured, the idea being that, by so treating it, the pterygium will not recur. This method of operation is seldom practised, and, I believe, has no advantage over excision or ligature.

Symblepharon is the deformity arising from the adhesion of ulcerated surfaces of the conjunctiva of the lids to similar abrasions on the surface of the eyeball.

These conditions arise—as a sequence of burns and scalds of the conjunctiva, or in any ulcerative condition in which both ocular and palpebral surfaces are involved—from keeping the ulcerated surfaces in approximation for a long period by poultices, compresses, and bandages, and the consequent attachments are permanent deformities, which can only be dealt with by operation. I append an illustration from a photograph of one of my own cases, in which both symblepharon and anchyloblepharon existed to a limited extent.

Fig. 14.

The operation essentially is a plastic one, the nature of which is determined by the extent and position of the

adhesion. The chances of success in freeing the lids and eyeball depend largely upon the extent of the adhesions. If they are limited to a small patch of the ocular conjunctiva, a cure can generally be effected by dissecting up the adhesions, suturing, if possible, the neighbouring conjunctiva across the denuded spot, and keeping the lid from contact while the cicatrization is in progress. But if the retrotarsal fold is included in the adhesion, it is extremely difficult to avoid a return of the contraction. A variety of mechanical adaptations have been, from time to time suggested, to keep the surfaces apart, but they have all been abandoned, it having been found that the contracting wound always pushed them out in spite of all precaution.

Two methods of dealing with this condition have been tried with success. The first of these—viz., to dissect up the entire extent of the adhesion, and to suture into the place a flap of conjunctiva taken from the eyeball—was first introduced by Mr. Teale, of Leeds, and is very efficacious when a sufficient extent of sound conjunctiva can be obtained. The appended illustration will better explain the position of these flaps than any verbal expla-

Fig. 15.

A. Tip of Symblepharon.
B. C. Flaps of Conjunctiva.

D. E. Sutured Conjunctiva.

TEALE'S Operation for Symblepharon.

nation. The point of the symblepharon A being left *in situ*, and the remainder of it dissected from the eyeball, the flaps B and C are to be dissected off the ocular surface and sutured into the position shown in Fig. 15, the flap B being applied to the lid surface, and C to the ocular surface. The edges of the conjunctiva whence the flaps have been taken are then brought together to complete the operation.

If the symblepharon be incomplete, or if there be any difficulty in getting the conjunctival flaps necessary for Teale's operation, a simpler procedure suggested by Arlt may be employed. A fine suture is first passed through the point of the symblepharon, and the ends left long and free, and the adhesion is then dissected up to its full extent, leaving its surface untouched. When the bleeding has ceased, the free ends of the suture are passed through two needles; the symblepharon is turned in on itself so as to place its conjunctival surface in contact with the denuded surface, and, the two needles being passed through the lid close to the orbital border, it is fixed in this position by tying the ends of the suture outside.

In any case these operations are troublesome, and frequently unsuccessful, but, if all fails, an attempt to transplant a portion of healthy conjunctiva, either from an enucleated human eye or from the rabbit, may succeed.

Anchyloblepharon is where the margins of the lids are adherent—wholly or partly—to each other, so as to close the palpebral opening. It arises not only from the cause above noted, but also from long-continued ulceration of the edges of the lids (blepharitis) injudiciously treated by bandaging. The adhesion together of the lid margins may very probably be accompanied with adhesion to the ocular globe, the position and extent of which should be ascertained before an operation is undertaken. If there be any lid opening (and there is almost always a small one near the tear ducts) a probe should be introduced through it, and, by

its means, the presence of attachments ascertained, and if it be found that there is any considerable attachment to the cornea the operation may be abandoned, for there will always remain a dense opacity fatal to vision. If the lid is drawn away from the eye and the patient directed to move the eye in different directions a judgment may be formed of the amount of symblepharon, when the adhesion of lids is not accompanied by adhesion to the eyeball. There is generally no difficulty in relieving this condition, the adhesions being simply divided and the lids kept separated until the new surfaces are cicatrised.

Lithiasis. This name is applied to the formation of minute calcareous concretions which form on the surface of the lid conjunctiva in gouty subjects, giving rise to great irritation of the conjunctiva generally. These are from calcification of the excretion from the glands on the inside of the lids, especially from the meibomian glands, and it will be liable to recurrence, causing at each return a fresh attack of conjunctivitis. The lids should be everted and carefully examined, and each concretion picked off with a cataract needle or the point of a Walton's spud. Sometimes the gland secretion is not actually calcareous, but cheesy, and it can then be pressed out of the gland duct. This removal of the concretion should be accompanied by internal treatment suitable to the gouty diathesis, if such exist, the purpose being to prevent a recurrence of the annoyance.

Oedema of Conjunctiva. Occasionally in elderly subjects, especially those whose kidneys are not working satisfactorily, a non-inflammatory oedema of the conjunctiva is developed, which is difficult to relieve. Incisions produce temporary benefit, but the ultimate remedy is in the restoration of the efficiency of the kidney and in stimulation of circulatory system. I have seen such cases associated with exophthalmic goitre and with weak heart.

Emphysema. When by any injury the cellular tissue of the orbit is brought into direct communication with the nasal passages or the ethmoid cells, the conjunctiva is liable to be distended with air whenever the patient blows his nose. The most usual cause of this condition is direct fracture of the nasal bones or a severe blow on the temple causing fracture by *contre coup* of the nasal or ethmoidal walls, and therefore, the occurrence of emphysema may be of importance as being diagnostic of dangerous injury. Sometimes the cellular tissue of the lid is similarly inflated, and we have a condition which at a glance might be mistaken for erysipelas. The true nature of the case is easily recognised by the crackling of the swelling when pressed with the finger.

Emphysema is, of itself, of no consequence, and it rapidly disappears on application of a compress bandage.

(To be continued.)

TWO CASES OF CEREBRAL TUMOUR.

Under the care of M. MARTIN DE BARTOLOME, M.D.,
Physician to the Sheffield General Infirmary; Lecturer on
Clinical Medicine at the Sheffield Medical School.

(For the report of these cases we are indebted to Dr. PORTER,
Physician to the Sheffield Public Hospital and Dispensary;
late House-Surgeon, Sheffield General Infirmary.)

M. G., *æt.* 14, who was said to have been always ailing and delicate child, was one of twins, her brother having died in infancy. She had two sisters living and in good health; both her parents were strong and healthy; and her family history good. She had had no accident or serious illness previous to that for which she was admitted into the Sheffield General Infirmary. About six months before she came under observation she was suddenly seized with violent pain in the head and vomiting. This attack lasted a few days, and was attributed by the medical man in attendance to some gastro-intestinal derangement. About a month before admission the patient began to lose the sight of both eyes simultane-

ously, and became quite blind in the course of about ten days. About three weeks later she was again seized suddenly with severe pain in the head and screamed violently, and after the attack lay for some hours apparently quite unable to move her head or limbs. The night previous to her admission she had another seizure, attended by slight convulsions and unconsciousness.

Four days after admission, her condition was as follows:—She complained at short intervals of pain across the vertex and right parietal region, also of pain extending along the spine and sometimes down the right arm, so severe at times that it caused her to scream loudly; some of the paroxysms were accompanied by vomiting. She slept only in short dozes, and more during the day, when the pain was generally less severe, than during the night. Her manner was dull, and she was very slow at understanding and answering questions. The pupils were widely dilated and insensible to light, a strong light making no impression on the retinae, which, when examined by the ophthalmoscope, showed well-marked optic neuritis. Smell and hearing were not affected. There was no facial paralysis or impairment of speech. In bed she seemed afraid to move without assistance, and called for the nurse when she wished to change her position; but when once on her feet she could walk tolerably easily if guided by the arm. There was some rigidity about the muscles of the left side of the neck, and she held her head very stiffly and somewhat inclined towards the left shoulder as she walked. There was no dragging of either foot, and no inequality of the movements of the two sides. Cutaneous and muscular sensibility were not impaired. There was no disease of either ear or history of pain or discharge there. The tongue was clean and moist; appetite very poor; bowels constipated. Temperature was normal, and there was no cough or sweating. The heart, lungs, and urine were normal.

A few days later her general condition appeared to have improved slightly, and the pain was less severe. It was remarked, however, that the tongue inclined slightly to the left on protrusion, and that the patient closed the left eye less perfectly than the right.

After only ten days stay in the infirmary her parents insisted on taking her home again into the country, where she died about a month afterwards, no post-mortem being obtained.

In the second case, the notes of which are appended, the patient was under observation for a much longer period and the diagnosis confirmed by post-mortem examination.

J. T. P., *æt.* 15, was one of a family of eight, having two sisters and four brothers living and in good health, but having lost one sister from "consumption." His father and mother were both living, the former being paralysed from the effects of a stroke. The patient himself had enjoyed good health up to four or five months before admission into the Sheffield General Infirmary, when he began to complain of occasional headache and attacks of giddiness. Shortly afterwards he was knocked down by accident and bruised his head, but this did not appear to cause any aggravation of his symptoms at the time. About a month later he had an epileptiform seizure in which he was convulsed and unconscious for about a quarter of an hour. After this attack headache and giddiness became almost constant, the pain being referred to the frontal region and the eyes. A fortnight before admission into the infirmary he complained of indistinctness of vision, his mother noticing that he squinted slightly at times, and within a week of his first complaining of his sight he became quite blind in both eyes.

On admission, the patient suffered from paroxysmal attacks of headache, accompanied, when severe, by vomiting, with a hot head and a flushed face. The pupils were equal, widely dilated, and insensible to

light, no impression whatever being produced on the retina by even a bright light; double optic neuritis, as in the former case. Hearing, taste, and smell unaffected. No facial paralysis, but well-marked inclination of the tongue to the right side on protrusion. There were no muscular twitchings, rigidity or paralysis of the limbs; no loss of sensation, hyperæsthesia, neuralgia, or abnormal sensations complained of; no disease of either ear; no impairment of speech. The tongue furred; bowels constipated; appetite fair. Urine normal in character, but rather watery and copious. Heart normal; no physical signs detected about the lungs. Patient rather thin and wasted; very weak, and walking with an unsteady gait.

About two months later patient complained of severe pain in the region of the heart and of a constant dry cough; his skin was hot and dry; temperature 101; pulse 112, small and feeble. The paroxysms of pain in the frontal region had become less frequent, and he complained of a dull constant pain in the occipital region. On making another examination of the chest a loud rasping double murmur was heard all over the cardiac area, but loudest behind the junction of the ensiform cartilage and sternum, apparently a pericardial friction murmur. The percussion note over the right lung was somewhat dull, and fine râles were audible over the whole of the right side of the chest with increased vocal resonance.

A fortnight later the friction sounds over the heart were no longer heard, but there was increased area of cardiac dullness. The cough still continued very troublesome, but there was no expectoration. At the right apex, beneath the clavicle, there was increased dullness with increased vocal fremitus, harsh tubular breathing, râles, and increased vocal resonance; at the right base, behind, dullness and abundant râles; at the left apex, beneath the left clavicle, slight dullness and a few moist sounds with jerky inspiration. The patient was in a hectic condition, with profuse sweating, the temperature ranging between 98 deg. and 102 deg., Fahr., presenting evening exacerbations and morning remissions.

Four months from the date of the patient's admission his condition had become very much worse. He was then very emaciated and feeble, the attacks of headache and vomiting were more frequent and the pain more severe, and were sometimes accompanied by convulsions and insensibility continuing for an hour or more. His intelligence had suffered considerably, and he became delirious towards night. His tongue was dry, brown, and fissured, and his gums and lips coated with sordes; the bowels, which throughout had been obstinately constipated, could only be made to act at all by large doses of purgatives and enemata. After lingering for about a fortnight in this condition the patient died rather suddenly, directly after an attack of convulsions.

The following was the result of the post-mortem examination, made twenty-seven hours after death:—

The body was very thin and emaciated. On removing the skull cap the vessels of the pia mater covering the hemispheres appeared very congested, and the membrane was studded here and there with small patches of lymph. On removing the brain no tubercle could be detected in the pia mater at the base, or elsewhere; on section both lateral ventricles were found distended with fluid; the substance of the cerebrum appeared healthy. The cerebellum weighed 7 ounces (5 ounces 4 drachms being the average weight in the adult); on its upper surface was a large non-vascular growth of dry, yellow, cheesy appearance and consistence, presenting the characters of a mass of yellow tubercle. It was about the size of a hen's egg, more or less oval in shape, flattened on the surface, and occupying almost the whole of the right lobe, the small middle lobe, and part of the left lobe. It was well defined though not encapsuled, and the surrounding tissue appeared quite

healthy. On opening the thorax both lungs were firmly adherent in several places, the right lung over nearly the whole extent of its surface. On removal from the chest the right lung weighed 14½ ounces; and on section was seen to be studded with miliary tubercle, the apex being quite solid with deposit; there were no cavities. The left lung weighed 12 ounces and was also studded, more sparingly, however, with tubercle in its upper lobe. The pericardium was found to be adherent to the surface of the heart all over, and on detaching the two layers of membrane some patches of miliary tubercle were seen on the anterior surface of the reflexion covering the heart. The valves of the heart were quite healthy, and there were no signs of endocarditis. The mesenteric glands were many of them enlarged and caseous; other organs were healthy.

The cerebellum and growth are at present in the museum of the Sheffield General Infirmary.

It is much to be regretted that no opportunity was afforded of confirming the diagnosis and ascertaining the nature of the growth in the first case. In both cases the age of the patient was the same and was that most favourable to the development of tubercle, which in one case it proved to be post-mortem; and although in the other the evidence of tubercle elsewhere, of family predisposition, and even of high temperature, was wanting, it seems doubtful if that would justify an opposite conclusion. The early history of both was that characteristic of cerebral tumour and nothing more, and under observation an adequate examination could only be made in the last case as the first patient left the infirmary after a stay of only a week or so. Headache, cerebral vomiting, and more or less suddenly developed amaurosis appear to be the principal symptoms in a very large proportion of cases of cerebral tumour; and it appears to be quite the exception to be able to localise the exact situation of the growth by phenomena due to local nerve irritation or paralysis. The situation of the pain in the head is generally no indication whatever of the seat of lesion; but the constant pain in the occipital region complained of towards the close of the second case may have been caused by the stretching of the tentorium or pressure on its nerves. Here the situation of the tumour, away from the large ganglia and nerve tracts, would fully explain the absence of local nerve irritation or paralysis. The character of the symptoms would also depend to some extent on the rapidity of growth and vascularity of the tumour; slowly-growing and non-vascular tumours causing less interference with the circulation, and consequently with the function of the surrounding brain tissue, than those whose size is subject to variations corresponding to the state of tension or otherwise of their vessels, and the condition of the circulation.

It seems difficult to account for the early and complete amaurosis in cases of cerebellar tumour except by compression of the venæ Galeni at their entrance into the straight sinus, producing effusion into the ventricles, which in turn would produce compression of the cavernous sinus and so venous congestion and structural changes in the retina and optic nerve. When amaurosis is the result of direct pressure upon the nerves and centres of sight, one or more of the motor nerves of the eye is paralysed also, from proximity to these structures at the base of the brain.

LAST week suspicion was aroused by the finding on the premises of the County Lunatic Asylum at Mickleover, Derbyshire, the head of a child near a water tank. The drains were at once flushed, and the rest of the body of the child, cut up into small portions, was discovered. The matter is at present under investigation.

Clinical Records.

ST. MARY'S HOSPITAL.

Minute Epidemic of Influenza in a Hospital Ward.

Reported by DR. C. HANDFIELD JONES, F.R.S.,
Physician to the Hospital.

On the night of Sunday, January 13th, 1884, the occupants of three beds at the northern end of Cambridge ward, St. Mary's Hospital, were taken ill. They had all appeared fairly well during the evening, and continued so till they went to bed. Bed 7 is next to a door opening into a room used for examination of urine, laryngoscopic and ophthalmoscopic work. Bed 9 is close to another door which communicates by a short passage traversing a bath-room with the large Albert ward. This bed may be somewhat exposed to draughts, but not the other two.

S. T., who occupied No. 7, is a man, *æt.* 46, who was admitted with hemiplegia affecting sensation as well as motion of the right limbs, probably resulting from intracranial syphilis. He was taking potassæ iodide, *gr.* xv., *ter die*, under which he had improved a good deal. He was taken ill on the night of the 13th with flushed face, severe headache, slight sore throat, and very copious vomiting. His temperature was normal before his illness, but rose to a maximum of 102° on the evening of the 14th, then declined to 99·6 at p.m. of 15th, and remained at the same on 18th p.m. Unfortunately it was not taken on the 13th when he felt weak and trembling. He had besides marked flushing of the face, severe headache, and very copious vomiting, with slight sore throat. He is subject to attacks of a similar kind, but only trifling, nothing like this.

F. L., *æt.* 42, convalescent from rheumatism, was taken ill on night of 13th with flushed face and very severe sore throat, but had no recurrence of rheumatism. On 14th he had shivering and felt nervous, and the first sound of his heart again became very weak, as it had been some days before. His temperature on 12th was 98·8 a.m., and 99 p.m.; on 13th was not taken; on 14th was 100·3 a.m., and 104 p.m.; on 15th was 101·2 a.m., and 101·9 p.m.; on 16th was 99 a.m., and 99·6 p.m.; on 17th and 18th was 98 a.m., and 99·4 p.m. His bed was No. 8. He had kept his bed all the evening.

L., *æt.* 21, was convalescent for 17 days from doubtful typhoid, attended with a good deal of bronchitis. He was taken ill in night of 13th like the others. He had headache followed by sore throat, felt very hot during the attack, but not weak. Before the catarrh he had been taking bark and ammonia, *ter die*, and on 14th this was changed for salicylate mixture and chlorate of potash gargle. He is now (19th) quite convalescent. His bed was No. 9.

This minimal outbreak of catarrhal disorder affecting only three persons occupying adjoining beds, the only ones at this end of the ward, and no others, may be deemed worth recording by reason of its very littleness. Had half the population (12) of the ward been affected it would have been no marvel; but that so few should have suffered, and those men lying side by side, implies surely a strange limitation of the morbid agency. It reminds us of the instances we have heard of cholera attacking one side of a street. It is true that L., No. 9, had a temperature of 101·4 in the evening, a few hours before the overt symptoms set in, but as he was up and about, mingling with the other inmates, it is hard to think that he could have infected his two neighbours and no others. Nothing similar that I know of has occurred in any other medical ward of the hospital. One patient in Cambridge ward had a slight sore throat a few days before the 13th.

A RETIRED army surgeon, Mr. T. M. McCully, of Manchester, was non-suited in an action against a patient for fees for professional attendance. The judge considered the conduct of Mr. McCully very singular for a medical man, and as the jury disapproved of the language used towards the wife of the said patient, they brought in a verdict in favour of defendant.

Special Articles.

HOME HOSPITALS.

HER MAJESTY THE QUEEN has consented to become the Patron of the Home Hospitals Association for paying patients, and has given a contribution which will constitute her a governor of the association. Three years' experience of the working of the pay hospital system, as tested by the Association at their home hospitals, 16 and 17 Fitzroy Square, has shown that the demand for admission is much greater than the amount of accommodation at present provided.

It was a portion of the original scheme, as submitted to the public at a meeting at the Mansion House in 1877, that if success attended the establishment of home hospitals for acute disease, home hospitals for convalescent patients should be opened at the sea-side and elsewhere. The home hospitals for acute disease having proved in practice so complete a success, the committee have determined to establish a convalescent hotel, or home hospital, where anyone recovering from sickness will be received, and isolated, so as not to be a danger to others, whilst being freed from any influence which is likely to militate against his rapid and permanent recovery. It is proposed that each convalescent home hospital shall be provided with a resident medical officer, with skilled and competent nurses, and with a *cuisine* of a special character. Each inmate will find there, neither the noise, the absence of privacy, or the general bustle of a hotel, on the one hand; nor the damp sheets, slipshod attendance, and great discomforts of ordinary lodgings, on the other. At the present time, when a patient becomes convalescent, and when he is ordered by his doctor to seek change of air, where to send him becomes a question of difficulty and worry, in proportion to the serious nature of the attack from which he is recovering. A rapid recovery largely depends upon the wisdom of the choice, and the absence of the proper accommodation has not unfrequently produced a relapse. Indeed, the need of a convalescent home hospital for paying patients for the treatment of patients recovering from infectious diseases, has become so urgently necessary, that most families have, at some time or other, felt the want of such an establishment very sadly indeed. It is proposed, further, to undertake to remove the patients from their residences to the home hospital and to provide the necessary precautions *en route*, which are urgently demanded by the public health and the patients' welfare.

It will be necessary to raise £10,000 to enable the Home Hospitals Association to establish and open the convalescent branch. The Association not being a commercial undertaking, but being registered at the Board of Trade as a philanthropic institution, has obtained the necessary capital previously on the same system as that which embodies the financial principle upon which the colleges at the universities and many of the public schools were originally founded. Contributors of fifty and twenty guineas each become eligible for election as governors and members of the Association, with the privileges of obtaining, (1) priority of admission for themselves and their families when ill, and of two nominations each year, if governors; and (2) of priority of admission for themselves only, if members. Owing to the demand for admission, a governorship at the present time confers substantial advantages, and the addition of a home hospital for convalescents will increase that demand, and enhance the value of governorships and memberships of the Association. The £10,000 additional capital which the committee now require to establish the Home Hospital for Convalescents, will enable them to elect about three hundred

new governors and members, and it is anticipated that the substantial advantages offered to heads of families, to bachelors, and other members of the community, in return for their subscriptions, will be so much appreciated, that the applications for election, which should be addressed to the Treasurer, care of Messrs. Cox & Co., Craig's Court, S.W., are likely to far exceed the number at the disposal of the committee.

ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

The Pathological Section met at the Royal College of Surgeons, Friday, January 4, Dr. HENRY KENNEDY in the chair.

Dr. BENNETT, Sectional Secretary, read the minutes of the previous meeting, which were signed.

ARTHRITIS DEFORMANS FROM THE HORSE.

Dr. ABRAHAM made a communication on this subject, a specimen of arthritic disease involving the manus of a horse. He said: Chronic rheumatic arthritis appears to be by no means uncommon in the horse. The specimen in question (which he exhibited) seemed to me, however, to be such an extreme example of the affection that I thought it would be a sufficiently interesting object to bring under the notice of the Pathological Section. The bones are those of the right manus of an under-bred and aged mare. The carpo-metacarpal articulation is quite healthy; but there are two or three small rough osseous outgrowths near the upper ends of the metacarpals—that is to say, there is a tendency to osteophytic outgrowths from the bones themselves, quite independently of the articular surfaces. The lower end of the cannon bone (middle metacarpal) is, on the other hand, all around the seat of osteophytic deposit. Several of the dendritic masses are loose, and the larger ones measure upwards of two inches in length and one inch in breadth and in thickness. The articular surface for the first phalanx, or greater pastern, is on the left side for more than half of its extent, rough, and quite denuded of cartilage. The greater part of the surface is, however, not much altered, although on the borders of the denuded part are situated three narrow bands of eburnation. From the way the articulation looks in the specimen, there could have been but little movement in the joint, and it is evident that the manus from this point must have been permanently fixed, without ankylosis at an angle so as to point backwards and somewhat inwards. The greater pastern is nearly everywhere enveloped in an enormous more or less continuous irregular bony mass, which above greatly enlarges and deepens the socket of the metacarpophalangeal joint in a manner typical of the so-called "rudimentary bones." A considerable portion of the upper articular surface on the inner side is denuded and rough, and there are one or two porcelainous lines and points corresponding to those on the bone above. The irregular bony outgrowth has included, as it were, the posterior sesamoid bones, which have thereby become firmly ankylosed. The lower articular surface of this phalanx has for the most part disappeared, an irregularly cavernous space occupying its inner two-thirds. The small piece of surface which remains on the outer half shows a large characteristically eburnated patch. Corresponding to the cavernous part of this surface, a similar irregular excavation is seen to occupy the adjacent portion of the "lesser pastern" (second phalanx); so that when the bones are in position these parts can be closely approached. It is probable that here the loss of substance or atrophy had been caused chiefly by pressure. At the same time, the surfaces have some appearance of erosion by pus. That part of the articular surface of the lesser pastern which ought to be opposite to the eburnated patch on the greater pastern is for the most part eroded, and is only polished along a line on the outer rim. The articulation of the lesser pastern with the "coffin bone" (ungual phalanx) is healthy, although the latter bone has thrown out some irregular growths outside the articular surface. The term "arthritis deformans" is in one sense eminently applicable to this case, for before the specimen was macerated and the bones separated, the general distortion was so great that it was hard to resist the idea of dislocation and

fracture. From the awkward position of the bones, the flat of the hoof became useless for support, and not meeting with attrition, the horny matter continued to grow. The hoof became thus curiously curved laterally, and it now weighs when separate $4\frac{1}{2}$ lbs. This is a good example of the overgrowth of an epidermic structure when relieved of its legitimate wear and tear, and it reminds one of the big toenails of bed-ridden paupers, which are so common in museums. For the sake of a more thorough examination the greater portion was longitudinally sectioned, and fragments from the centre of the bone, as well as pieces of the osteophytia, were ground down for microscopic observation. On the cut surface the original contour of the bone can with difficulty be made out, and to the naked eye there is but little difference distinguishable between the textures of the osteophytic bone and of the bone proper. The saw has escaped a cavity situated in the midst of the bone just below its centre. No communication with the outside has been traced. It is occupied in parts by a powdery mass, the remnant of an abscess. The thin sections taken from the centre of the bone are very similar in microscopic character to the sections taken from the outgrowth. In both cases the bone deposition is irregular, especially with regard to the lacuna, which vary much in size and shape, have indistinct or few canaliculi, and are singularly absent in some places and closely massed in others. In the specimen, indeed, there seems to be on the whole more inflammatory bone disease than joint disease.

The CHAIRMAN asked, Was there any suppuration?

Dr. ABRAHAM: I did not find any. I did not examine the specimen until it was quite macerated.

Dr. BENNETT said that, although they seldom saw specimens of this sort, he believed the disease was common enough in horses. While there were differences from the disease as presented in human subjects, the essential features were the same in both. There was also in the specimens an exact repetition of the diseased conditions seen in the fossil specimens, *Cervus mejiaceros*, or Irish elk, which were preserved in the Museum of Trinity College, and also in the College of Surgeons, the disease being in all these cases true rheumatic arthritis. In the last number of the "Pathological Transactions," of London, reference was made to the occurrence of rheumatic arthritis in human skeletons lately dug up in London from a Roman tomb of the fifth century, and in those found at Pompeii, as the earliest known examples of the diseases; but a still earlier date might safely be assigned to the *mejiaceros*.

CHAIRMAN: Were both the horse's legs affected?

Dr. ABRAHAM: I think not. The animal while living could not walk on the diseased hoof, but dragged it under it.

Dr. DOYLE mentioned that he had a horse suffering, he believed, from this disease, and the animal was a good galloper and a capital jumper in the field, but when leaving the stable in the morning he used to be quite stiff in the parts of the legs connected with the hock joint. After he had moved about for awhile, however, the stiffness would disappear, and he would get quite well. In the Richmond Hospital the late Surgeon Adams used to draw attention to the fact that patients suffering from rheumatic arthritis had a difficulty arising from stiffness, which disappeared after they had moved about for awhile. In the majority of the cases of arthritis at that hospital, as he remembered, the disease was not confined to one joint, but the joints of both sides used to be affected.

Dr. ABRAHAM, in reply, said he forgot to mention, in the case he had brought before them, the navicular bone was quite free. There was a cavity in the centre of the greater pastern, which contained a powdery mass, like what would remain after an abscess, although the occurrence of abscesses was not common in chronic rheumatism. There was also an appearance as if the joint had been eroded with pus. The joint seemed to be more affected than the articulations, so that one would be inclined to suppose that the disease was one more of the bone on the periosteum than of the cartilages. The ordinarily received opinion was that this disease commenced in the synovial membrane and the cartilages, and the human specimens in the Museum of the College showed that beyond a doubt. It was possible that there were other diseases nearly allied to the ordinary chronic rheumatism, but differing from it in some points, and it was also possible that the disease of the horse illustrated by the specimen was a variety of it. The bones of the *mejiaceros* upstairs showed a small amount of affection.

TUMOUR OF THE INFERIOR MAXILLA.

Dr. ABRAHAM made, on behalf of the President, who was

unavoidably absent, a communication on the subject of sarcoma of the lower jaw. The patient first noticed the tumour in March last, and on the 15th September she was admitted into the Richmond Hospital. In May she had been advised to have it removed. It commenced at the lower and outer part of the jaw, in front of the masseter, and involved the whole substance of the bone as far as the symphysis. The cheek was reddened, but not thickened or adherent, and from the way the cicatrix puckered up during the healing, he suspected that infiltration had commenced in the soft parts. The last report received of the case confirmed that view. He (Dr. Abraham) had examined the tumour, and the first portion of it that he inspected appeared to have the nature of a young fibroma, but on looking at two or three other sections, it turned out to be a sarcoma. One of the specimens under the microscope showed the fibromatous texture, and from another it was apparent that the tumour was a rapid-growing one, with ossification going on. All that part was undoubtedly sarcomatous, and cells of round, spindle, and in fact of all sorts of forms, could be seen.

Dr. BENNETT said that an important point was that, while the skin and surrounding parts and glands were free, the tumour yielded a crepitus to the touch, which made it probable that the tumour was of benign character, but that the symptoms often taken as evidence of benignity were not to be absolutely relied on, for he believed the tumour was rapidly returning.

FRACTURE OF THE NAVICULAR BONE OF THE FOOT.

Dr. BENNETT submitted two examples of a fracture of the navicular bone which he believed had not been heretofore described. The first and older of the two specimens came into his possession some years ago from the dissecting-room, so that of course he had no life-history of it, and it had since remained in the Museum of Trinity College. This year a second and more characteristic specimen of the injury came into his hands similarly, and without history. He at once observed its identity with the former example, in both the articular surface of the bone which receives the head of the astragalus, presenting distinct evidence of united fractures which traversed in a regular line the upper and outer part of the surface. On turning to the opposite articular surface which supports the cuneiform bones, one is surprised to find only the most trivial traces of fracture marking the upper margin of the upper and outer part of the fracture. In so thin a bone as the navicula, one would expect to find a close correspondence in the lines of fracture, no matter how arising, on its opposite faces; but it was evident that the planes of fracture originating in hollow depression on the proximal surface had passed with extreme obliquity to the free margin, almost avoiding the distal surface. He concluded that the force which caused the injury in both cases was a degree of crushing which, if more strongly applied, would have produced dislocation of the head of the astragalus upwards and outwards. With the specimen last obtained he had the other tarsal bones and exhibited them, as proof that the injury in this case was limited to the navicular bones, the others being normal, except only the head of the astragalus, which showed slight trace of change in form, such as its articulation with a bone whose surface was altered by fracture would readily induce.

DISLOCATION OF THE TWELFTH DORSAL VERTEBRA WITH FRACTURES OF THE RIBS AND THEIR CARTILAGES.

Dr. BENNETT exhibited these specimens, and detailed the history and symptoms observed during the life of the patient. On Nov. 2, 1883, a middle-aged man was admitted to Sir Patrick Dun's Hospital in a condition of profound collapse. He had, while half-drunk, fallen from the shaft of a float between the horse and the body of the vehicle, so that he was dragged along for some distance between the low axle and the ground. His lower limbs and the trunk from the ensiform cartilage downwards were absolutely paralysed. All power of motion, sensation, and all reflex motions, were absent. The bladder and rectum were powerless. In two days sensation was restored to the level of the hypogastrium and inside of the thighs, and there remained stationary. The urine was acid, and free of blood, and was drawn off with a catheter until the eighth day. Pain and vomiting were the prominent symptoms after reaction was established. Two days after admission the patient broke out in delirium tremens. He had had the horrors before, and remained delirious till the 8th. On the 13th he again became delirious, and next day he passed for the first time bloody urine, the urine having become alkaline on the 9th. He had no bedsores, being placed from the first

on a water bed. Only a minute eschar formed on one toe where the bedclothes lay heavily. He had a vesicle above the right ankle on the day after his accident, remote from any seat of pressure or of any part exposed to the heel of the foot. This vesicle grew for a couple of days, and then remained stationary, ultimately drying up after the first week. The convex spines of the mid-dorsal vertebrae were covered on his admission by a large, ill-defined, bloody tumour, which precluded close examination in the early days, and the superintention of delirium rendered detailed examination during the first week impossible. From the advent of the hæmaturia on the 14th, when already catheterism was only performed occasionally, precluded the idea of this being its cause. But little benefit from treatment was obtained in the control of this symptom, and in fact the patient appeared to die from its severity and uncontrolled continuance. He died on Nov. 25, of asthenia. The fractures of the lower left ribs and their cartilages gave rise to much pain at first, but otherwise did little to hasten death. When emaciation became marked, after the delirium subsided, the projection of the first lumbar vertebra was indistinctly defined. At the autopsy, on reflecting the muscles of the spinal grooves, the superior oblique process of the first lumbar vertebra presented its articular surface free and unbroken in the groove on the left side. With difficulty, on complete dissection, it was found the corresponding process of the 12th dorsal was cracked at its base without any displacement or rupture of its fibrous investments. The opposite articular processes were normal. On section of the spine in the mesial plane, the body of the 12th dorsal was found displaced forwards and downwards. The anterior common ligament being stripped for a short distance from the 1st lumbar, the angle so limited was filled by debris of the intervertebral disc of the vertebrae engaged, and a few grains of bone torn off with its fibres; but nothing capable of being called a fracture of either body existed. The specimen, then, was one of unilateral dislocation of the 12th dorsal vertebra, with only the merest trace of fracture of one (the superior) of the articular processes engaged. The cord was found completely severed, the lumbar swelling almost completely involved in the crushing. With above and below compression of the cord was blood effusion for enough space to explain the abolition of all reflex movements. The chief interest seemed to be in the hæmaturia; no lesion of the bladder or kidneys existed in the way of rupture; but the kidneys were alike intensely congested and swollen, while their pelvis were filled with blood altered by its mixture with alkaline urine. Hence the cause of the bleeding was renal, and from both kidneys alike. The bladder was inflamed, but quite muddy compared with the kidneys. The specimens are preserved in the Museum of Trinity College.

The Section then adjourned.

SUB-SECTION OF ANATOMY AND PHYSIOLOGY.

At the opening meeting of the Sub-Section of Anatomy and Physiology, held in the Royal College of Surgeons, Professor J. M. PURSER, M.D., President of the Section, occupied the Chair.

Mr. J. F. KNOTT, Hon. Sec., read the minutes, which were confirmed.

DEMONSTRATION IN MICRO-PHOTOGRAPHY.

Dr. NEWTON DICKENSON gave a demonstration in the art of micro-photography, with an apparatus which he believed to be the simplest and most efficient as yet produced. Photographs by his method could be taken either by day or night without any of the complex and expensive arrangements at present considered necessary for their production. The apparatus he described at full length, demonstrating its use by preparing some specimen photographs.

THE HOMOLOGIES OF THE MUSCULUS STERNALIS AND THE SO-CALLED PECTORALIS QUARTUS.

Dr. CUNNINGHAM made a communication on the homologies of the musculus sternalis and the so-called pectoralis quartus, which he illustrated with diagrams. He supported the view advanced last session by Mr. Abraham that the musculus sternalis is an aberrant part of the great pectoral muscle. He had succeeded in tracing its nerve supply from the internal anterior thoracic nerve. The pectoralis quartus he regarded as a piece of the panniculus carnosus. Its nerve supply, which he traced in the sloth bear, proved this.

Mr. ABRAHAM was pleased that Prof. Cunningham had so

ably proved the idea which he had himself put forward last year. Although in certain text-books of anatomy the muscle in question occupied a small paragraph after the description of the great pectoral, the authors made no allusion to any connection between the two. In only one foetus out of three or four examined since his former communication did he find the muscle, and in that it was developed to a very small degree.

EXPERIMENTS ON THE PNEUMOGASTRIC NERVE.

Dr. SCOTT read a preliminary communication concerning experiments on the central end of the pneumogastric nerve. He pointed out that in some experiments performed by Dr. Purser and himself on the central end of the vagi, certain facts were observed differing from those hitherto described. Firstly, on section of one vagus the heart beat was not slowed, but there was a slight fall of blood pressure; secondly, on section of both vagi, a considerable rise of pressure ensued, associated with a slowing of the heart beat, these being independent of the stoppage of respiration. The foregoing facts would show that the heart is inhibited by other means than the vagi. The respiration, also, was differently effected when one or both vagi were divided. In the former case the stoppage was always followed by expiration; in the latter, by inspiration.

The PRESIDENT testified that the tracings exhibited were accurate copies of the original tracings. They were very curious in a great many respects, and the phenomena were extremely complicated, indicating not only the action on the nerves, but the influence produced by the asphyxia.

Dr. SCOTT, in replying, observed that it was only after the section of both vagi that the beats made their appearance.

The Sub-Section then adjourned.

LIVERPOOL MEDICAL INSTITUTION.

THE eighth ordinary meeting of the session was held on Thursday, January 31st, Dr. GEE, President, in the chair.

The pathological specimens exhibited were—

A STOMACH FROM A CASE OF POISONING BY CARBOLIC ACID, shown by Dr. Chisholm. The patient drank, as usual, by mistake, a quantity of crude carbohc acid from a bottle. The quantity swallowed was at least five ounces. No vomiting followed, and death took place 18½ hours after the misadventure. The lips and mouth showed but slight traces of the caustic effects of the poison, and none could be traced beyond the stomach, showing that none, or but the smallest possible quantity, had been allowed to pass the pyloric orifice;

VESSELS FROM A CASE OF SPONTANEOUS GANGRENE, shown by Dr. Creswell Rich, in which a large thrombus blocked up the right iliac artery completely, thus producing gangrene of the corresponding leg, and almost, but not quite as completely, the left common iliac; and a

LARYNX AFFECTED WITH MEMBRANOUS GROUP, by Dr. Greves. In this case the disease was stated to be of exceedingly long duration. The child, always weakly, was attacked 14 days before admission into the Children's Infirmary. At this time there was cough at night, but no dyspnoea. On admission there was dyspnoea and lividity of the lips; the tonsils were red, but no false membrane could be seen. The patient gradually got worse, and tracheotomy was performed. After the operation a membranous cast of the trachea was coughed up, and the breathing was much relieved, but the patient sank and died. Thirty-six hours afterwards, on post-mortem examination, the trachea was found to be tolerably free from false membrane, the bronchial glands were enormously enlarged, and the apices of the lungs were affected with pneumonia.

Professor PARKER then gave a detailed history of a

CASE OF COMPOUND DISLOCATION OF THE ELBOW, with division of artery and vein, which healed with full restoration of movement. The case on admission into the Royal Infirmary did not look very hopeful, but Professor Parker decided to make an attempt to save the limb. The wound was dressed antiseptically, without sutures or splint, the arm being kept at rest by a sling. The process of heal-

ing was aseptic throughout its course, although the patient was a hard drinker. He thought sutures should be avoided in such cases, as free discharge should be allowed. He then related the particulars of a

CASE OF IMMEDIATE GANGRENE OF THE UPPER LIMB,

successfully amputated at the shoulder-joint six days after injury. The patient, a man, *set.* 53, met with a severe crushing injury from a locomotive engine, and was admitted into the Royal Infirmary the day following. At this time he was cold and haggard. The upper limb was gangrenous. A large blood tumour occupied the upper arm and chest. The limb was pulseless, and there was neither movement nor sensation; there was no aperture through the skin, however. The man's condition was so bad that he would not amputate at the time. The limb was dressed antiseptically, and the patient then had three good days and nights, and improved in colour, &c. On the 4th day he was fit for amputation. The gangrene was white; no decomposition had taken place; the lower part of the limb was warm, but only from lying in contact with the trunk. The line of demarcation was marked, but not clearly. Operation was again postponed. On the 7th day the livid hue had deepened, but there was still no blackness. Amputation at the shoulder joint was now performed. Nothing but skin and three nerves required division. The patient made a good recovery, and was exhibited at the meeting.

Dr. BARR showed cases of

EMPHYEMA AND MITRAL AND TRICUSPID STENOSIS.

The first case was that of a boy admitted into the Stanley Hospital in an extremely emaciated condition, suffering from emphyema. The chest was drained in the ordinary way by an upper and a lower opening from August to December of last year, but the openings did not close. On December 12th Dr. Whitford removed 1½ inches of the tenth left rib, and laid the cavity open. The wound was then washed out with a solution of hyd. bichlorid., *gr. j. ad 5j.*; and afterwards with a solution half this length. Recovery then took place.

Dr. ALEXANDER said that he had removed portions of three or four ribs in one case. In a second he had removed two inches of five ribs in the most prominent part, and six months afterwards two ribs completely as far as the epiphysis. The chest wall then fell in, but union did not take place, and the patient ultimately died.

Dr. BURTON was glad to learn that others in Liverpool besides himself were using a solution of corrosive sublimate as a surgical dressing. He was in the habit of using it in the strength recommended by German surgeons—1 in 1,000 for washing the wound, and 1 in 2,000 for subsequent dressings. Even at this strength he had seen blistering of the skin in the vicinity of the wound follow its employment.

Dr. DAVIDSON thought resection of ribs must be only exceptionally required—that time should be given. He did not think the lung expanded much. In Dr. Barr's case the patient was a boy in whom there was a good deal of vitality.

Dr. ALCHER did not see the need for two openings, one above and one below. He did not think it necessary to remove part of a rib, and that in time the case would have ended favourably without any such operation.

Mr. PARKER, Drs. ROBERTSON, BLIGH, and the PRESIDENT then spoke, after which Dr. BARR replied.

THE highest annual death-rates in the large towns last week from diseases of the zymotic class were—From scarlet fever, 3·7 in Leeds, 2·1 in Preston, and 1·7 in Birkenhead; from measles, 1·8 in Derby, and 1·3 both in Salford and Oldham; from whooping-cough, 1·8 in Brighton, and 1·6 in Sheffield; and from "fever," 1·4 in Blackburn. The 35 deaths from diphtheria included 16 in London, 5 in Glasgow, 3 in Dublin, 3 in Birmingham, and 2 in Liverpool. Small-pox caused 2 deaths in London and 2 in Birmingham.

WEDNESDAY, FEBRUARY 6, 1884.

THE COMING MEDICAL REFORM BILL.

THE interest in the Medical Bill, which we earnestly hope, and confidently expect to see introduced to Parliament within the next few days, is reaching a culmination so rapidly that it is necessary for us to sketch briefly the provisions of last year's Bill, upon which it is to be assumed the coming measure will be constructed.

The objects of the reform are fourfold:—

- To establish a standard of the *competency* of the practitioner, without which no one should be registered as qualified.
- To reconstitute the General Medical Council so that it may be more independent of the interests of licensing bodies than heretofore.
- To strengthen the law against unlicensed practice.
- To provide for the admission of Colonial and foreign diploma-holders to home practice under due restrictions.

The first of these objects (a) is to be attained by the holding of a central examination uniform in scope and in severity, through which every person seeking admission to practice *must* pass, no matter what diplomas or degrees he may possess, or may afterwards take. This “competency” examination is to be the final one of a series of tests, the primary examinations, one, two, or three in number, being left to the “recognised examining authorities,” but subject to inspection and approval by the central examining board.

As it would be inconvenient, if not impossible, to

have the final “competency” examination held by a single central court of examiners, it will be held by a separate court for each division of the kingdom, care being taken that the three examinations will be, as nearly as possible, identical in scope and severity. For admission to the primary sessional examinations the “recognised examining authorities” may charge what fees they please, and exact what curriculum they please, and they may accept what standard of answering they please, subject to the supervision already stated; while for the final “competency examination” the local supervising board will fix an admission fee, and will set forth a course of study which will be as nearly as possible uniform throughout the kingdom. When the candidate has passed this “competency” examination he will be placed on the Register and be authorised to practise. If he wishes for degrees or diplomas he can take them, and no limitation whatever is put upon the colleges or universities as to when, how, or for how much, they will grant these distinctions. They may give them to the examinees without further examination or without additional fee, or they may put him through any additional study and any additional payment they think necessary to maintain the *prestige* of their degrees, but these degrees or diplomas will no longer confer any right to practise, though they will be inserted in the Medical Register opposite the name of the examinee as evidences of his culture. So much for the scheme of examination. It will be seen that its intention is:—

1. To reduce the number of licensing centres from 19 (as at present) to 3, thus bringing them within supervision and control, which the 19 bodies never have been.

2. To secure that the practitioner of the future shall, at least, be *competent*, while leaving it to his own free will whether or not he will also be *cultured*, and leaving it perfectly free to the colleges and universities to fix their own limit of the culture necessary for their degrees.

Now it must be at once admitted that the licensing bodies are here deprived of the right to license practitioners. But while admitting this, we insist that such deprivation is inseparable from any effectual scheme of reform, and that it is effected by the Bill in such a way as not to prejudice the interests of any licensing body which deserves to be protected. Thirty years of experience of the working of the Medical Act has established beyond dispute that a certain number of licensing bodies have thriven, and if permitted, will continue to thrive, by admitting incompetent practitioners on cheap and easy terms, and the same experience has shown conclusively that there is no possible means of controlling 19 licensing bodies by any system of supervision. There was, clearly, nothing for it but to bring the system within control by reducing the 19 examining centres to one tripartite body, whose standard of education and examination it would be possible to fix at the level of that “competency” which the State is bound to insist upon in the public interest.

But in thus taking away the qualifying rights of licensing bodies, the Bill has been most careful to interfere in no way with their management of their

own affairs. It leaves the colleges to hold all their examinations exactly as they do at present, and it accepts the primary examinations if they come up to a reasonable level as sufficient title for admission to the final "competency" examination. It allows these institutions to charge exactly what suits them for these examinations, and it provides that the surplus of the final examination fee shall go back to these institutions for their support. Furthermore, it does not in any way interfere with those bodies who wish to keep up the rank of their degrees.

But it is predicted by those who desire to resist reform that the examinee, being entitled to practise without one, will take no degree or diploma, and that the colleges will thus be starved out of existence; to which we reply, *first*, that even if the examinee were content to go into practice without such a distinction, still the colleges would not be materially worse off than at present, because they would have all the emoluments derived from the primary examinations, and also the surplus of the fee for the final examination. The first of these emoluments they would fix for themselves as at present, the second would be fixed by the supervising board formed by themselves, and would, we firmly believe, be not a shilling less than they now receive from their diploma fees. Besides these two sources of income, these institutions would also retain their right to charge what they pleased for their diplomas and for their Fellowships or other higher degrees; and, on the whole, we declare our belief that, speaking generally, they would not be a penny the poorer or less influential by the passing of the Bill, even if the examinee were content to enter practice without a diploma. But, as a second reply, we contend that not one examinee in 100 will do this, for we can point with confidence to the fact that a mere licence to practise never has been the chief object of the practitioner. He well knows that his chances of success in money-making depend on the estimate the public has of his attainments, and he has, therefore, always seen the necessity of obtaining one or more decorative qualifications in addition to the mere licence to practise. Let anyone who doubts this turn to the pages of the "Medical Directory" and satisfy himself of its truth.

But, under this Bill, there is an additional and very special reason why he should voluntarily seek a diploma, and that reason is that, if he does not do so, he has no title whatever by which he may designate his qualification. The Bill gives him none; the Medical Register simply enters him in a list and gives him none; and, if he lacks a diploma or degree, a blank stands opposite his name, indicating that he is one of the undiplomates.

Does anyone suppose that a student who has served four years in his school and college, passed three examinations therein, and paid his consecutive fees therefor, will go away into the world without asking for its diploma? We certainly have no such belief, and we regard this point as nothing better than a bogey lighted up for the purpose of frightening unthinking people into an unreasoning opposition to the Bill.

We shall next week discuss other points of the Bill.

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

We are at length within a measurable distance of the realisation of some practical reforms in the Council of the Royal College of Surgeons of England. For many years demands have been made for the readjustment of the relations existing between the Council and the Fellows and Members, and the Council has always met these demands in a peculiar and characteristic way. For a time it affected to be ignorant of them, but when this becomes obviously impossible it pretends to offer spontaneously that which otherwise it must yield by force.

The grievance of the provincial Fellows respecting compulsory personal voting at the election of members of the Council had to become almost insufferable; the opinions of the leading Fellows in the provinces had to be expressed in forcible and unequivocal terms; the tension of antagonism had to become extreme—before the Council would listen to any proposal to increase the facilities of voting by voting-paper at the elections. When it could no longer be withheld this alternative was announced with considerable obtrusiveness as the free-will and act of the Council.

It is indisputable that the formation of the Association of Fellows helped to quicken the political sense of the Fellows generally and to reveal the existence of rocks ahead. The motion brought forward by Mr. Cadge, to allow of non-personal voting, completed the despair and confusion of the obstructive members of the Council, while some of the more enlightened members of the Council gave the proposal cordial support; it is notorious that to others it was eminently distasteful. Every legitimate obstacle was imposed to its consideration, and had it not been for the very emphatic expression of opinion at the last election, it is possible that the attempts to defeat it would have been successful. It is characteristic of the official spirit now dominating the College, that when the Fellows had made it unmistakably evident that they would no longer be denied the privilege of voting by voting-paper, it should then be represented that the proposed alteration was autogenetic and altogether independent of external influence or suggestion. Be this as it may, the next election will, in all probability, be the last in which Fellows who wish to record their votes will be compelled to attend in person at the College.

Before even this proximate period comes round, the Fellows and Members may have an opportunity of considering more closely their relations to the Corporation. It is not so widely known as it should be that when the new Charter is prepared to enable Fellows to vote either in person or by voting-paper, other alterations are also to be included. The Committee of Council appointed to consider and report on Mr. Cadge's motion was, on the suggestion of Mr. Erichsen, asked to consider and report on the Charter and Bye-laws generally. The report of the Committee was presented at the meeting of the Council held on the 10th ult. The alterations proposed by the Committee are of a slight and fragmentary character, and so far from attempting to conciliate the Fellows and Members, they are designed rather to complete the autocracy and independence of the Council. Moreover, endeavours have been made to

keep the knowledge of these alterations from the Fellows and Members till it should be too late to modify or revoke them. It was even attempted, at the last meeting of the Council to hurry on the adoption of the alterations without waiting for the customary confirmation of the Members at the ensuing meeting. This has, however, been defeated by a notice of motion given by Mr. Erichsen, to the effect that the proposed alterations shall be submitted to a general meeting of the Fellows and Members.

This notice will be considered at the meeting of the Council to be held on the 13th inst. That it will now be carried there cannot be a doubt. Disagreeable and odious as it may be to some of the Members of the Council to have Fellows and Members taking an intelligible interest in the affairs of the College, the most redoubtable of opponents may be excused for lacking the courage to challenge a proposal so reasonable and right as that which seeks to submit proposed alterations in the Charters of a Corporation to the *Members of the Corporation*.

THE HOSPITALS ASSOCIATION.

It will be remembered that we commented last summer on several meetings which were held at the Society of Arts for the discussion of a proposal to found an association of persons interested in the administration of hospitals, and having for its object to promote the efficiency and prosperity of our medical charities. As the practical outcome of the movement thus initiated, an influential gathering, presided over by the Lord Mayor, Mr. Alderman Fowler, took place at the Mansion House, in London, on Friday last, when Sir T. Fowell Buxton proposed, and Sir R. Alcock seconded, and it was unanimously agreed—"That, in the opinion of this meeting, it is desirable to establish, under the name of the Hospitals Association, and on the basis of the constitution prepared and adopted by the Provisional Committee, an organisation for the consideration and discussion of matters connected with hospital management."

The objects of the Association are of a very admirable kind, and, as soon as they are more fully appreciated by the Committee than they appear to be at present, it is quite possible they may be fulfilled in a manner to bring about beneficial changes. At the outset, it is properly, and very clearly, intimated that the Association does not intend to pose as a reforming body; and thus the principal objection that might be urged against its existence is rendered negatory by its own explicit declaration, a very foolish suggestion to entitle it "The Hospital Reform Association" having been promptly negatived by the meeting. That there is abundant legitimate work ready to be performed by such an association is very apparent; as also is the fact that co-operation among hospital authorities would largely assist the introduction of improvements, and the equally desirable dissemination of knowledge as to bases of administration among many beneficent, but, it must be admitted, ill-informed supporters of the new movement. At once a variety of questions will arise for consideration as part of the duties to be discharged by the Association, such as those relating to payments by

patients, relative cost of maintenance, comparative values of dietaries, and equable distribution of relief. Any of these would profitably occupy the attention of a body of men willing to discuss them, for some time; and as it is clearly proposed to adopt into council representatives from all hospitals willing to nominate them, an enlightened diffusion of information may with justice be anticipated from such deliberations.

An instance of the mode in which the Association could render efficient aid to hospitals generally, was given by Major Ross, chairman of the Provisional Committee, in his introductory statement. This had reference to a Bill introduced into the House of Lords three years ago, a clause of which provided that the board of management of a hospital should be made personally liable for any expenditure of funds. Opposition to this measure was commenced by Christ's Hospital, and other charities joined it in fighting the Bill in the Commons, sharing, also, the expense thereby incurred. It will be a function of the Association, as a combination of hospital managers and supporters, to take note of any such threatened injustice in the future, and generally to keep a look out for new Bills likely to react injuriously on the special interests entrusted to its care.

Financial matters are, of necessity, likely to engage a large share of attention at the hands of the Association, for the desperate straits to which not a few important charities have of late been reduced must, ere long, necessitate immediate and urgently-needed changes. How the difficulty can be met will require to be carefully thought out and delicately handled; and the question cannot surely be approached with more encouraging prospects of successful solution than when debated by, and in presence of, officials representing the institutions directly concerned in the matter. Such an assembly will possess powers of invisible coercion, to which recalcitrant bodies must needs succumb; whereas they can safely repudiate suggestions emanating from quarters which are individually not concerned in the decisions arrived at. In this way it is possible that the advantages of an inquiry conducted by a Royal Commission, so long expected, so long delayed, will result from the formation of the new Association, and a redistribution of hospitals become one of the principal aims achieved through it. Only thus can the anomalies existing at present in London be remedied, and the wants of scattered millions now far removed from any general medical charity be sufficiently cared for.

The Association numbers a large proportion of influential members, well-known philanthropists, and others who have frequently proved themselves interested at heart in the great subjects that enter into its programme. It deserves to succeed in its efforts; and, wisely guided during its early stages, it doubtless will do so.

At a meeting of the Council of the Institute of Chemistry, on Friday last, Professor Odling, F.R.S., President, in the chair, the following were elected as Fellows of the Institute:—Dr. P. F. Frankland, Mr. W. Lapraik, Mr. A. Smetham, and Dr. L. T. Thorne.

Notes on Current Topics.

Dangerous Performances.

ANOTHER of those distressing accidents which so frequently attend the performance of sensational acts for the exhibition of which a certain class of people seem to possess an unnatural and morbid appetite, took place at Leicester on Thursday last. The victim in this case was the wife of a person who, under the title of Captain Austin, poses as a crack rifle shot at entertainments, and one of whose feats is the shooting of a potato from off the head of Mrs. Austin. On the night in question he succeeded in hitting the potato when firing in the usual position, and then while lying on his back, proceeded to repeat the operation. This time, however, his aim failed, and the bullet struck the unfortunate woman in the forehead, when she immediately fell bleeding to the ground. Medical assistance was at once obtained, and it was found that a wound had been inflicted three inches in length, but which it was anticipated would not be of a very dangerous character; so that Captain Austin has by rare good chance very narrowly escaped the crime of homicide. The comparative frequency of accidents resulting from rash and sensational performances has often been commented on in these pages; and we can but repeat that, so long as the laws which regulate such exhibitions maintain their present laxity, so long will the dangers that exist continue to lend an unhealthy surrounding to popular amusements. There is an undeniable attraction to music-hall audiences in performances that are attended with imminent risk to life and limb of the performers; and it is the duty of the State to interfere for the protection of those who are induced to pander for gain to the unnatural taste for excitement among frequenters of such entertainments as the one referred to.

River Pollution at Cambridge.

MAJOR TULLOCH, Local Government inspector, opened an inquiry at Cambridge on Thursday last respecting certain alleged defaults of the sanitary authority of that town in permitting pollution of the river by sewage matter. It has long been the custom to discharge the town sewage into the river, almost in the immediate vicinity of the boat-houses; and the existence of such a nuisance is not unnaturally complained of by undergraduates and others who are constantly in the habit of using the river for boating and health purposes. In a place like Cambridge there is especial reason why every precaution should be taken to preserve the purity of a running stream, and particularly of such parts of it as are largely resorted to by residents in the University and town. Visitors there are only too familiar with the unpleasant sights and odours experienced while boating, and although the backs of the colleges are not so bad in this respect as they were a few years ago, still it must be admitted that considerable room for improvement even now exists. If the result of the inquiry that has been called for shall be to remedy a state of things that constitutes a serious drawback to an important town, those who have demanded that it should be held may congratulate themselves on achieving a salutary result.

Dwellings for the Poor.

AN association entitled the Mansion House Council on Dwellings of the Poor, with the Lord Mayor as President and Treasurer, has been organised with a view to giving practical effect to the demands recently made for improved house accommodation on behalf of the poor of large towns. Two Committees have been formed from the Council—the first, the General Purposes Committee, to deal with re-housing and rebuilding schemes, and to watch legislative action and promote amendments where required. The second—the Central Sanitary Aid Committee—is promoting the formation and application of Local Committees in East, West, and North Marylebone, North and South St. Pancras, Holloway, Highgate, Hampstead, Islington, Paddington, Westminster, Brompton, Putney, the Potteries, Lambeth, Southwark, Bermondsey, Shadwell, Whitechapel, St. George's-in-the-East, Clerkenwell, and St. Luke's. It is proposed to extend these Committees until the whole Metropolitan area is covered. To ensure uniformity of action and avoid unnecessary clashing, each Committee is limited to the working of its own clearly-defined area; and rules for the guidance of members, together with a brief synopsis of the Acts as they apply to the various nuisances and defects of insanitary dwellings, have been prepared and will be supplied gratis. Such a union of actively-interested workers as this promises to be can do an immense amount of service by collecting information from all quarters, and submitting it for combined consideration and discussion. A great deal will have to be done, however, in preliminary inquiries before any definite advance can be made in the direction of building and alteration; but that some tangible benefit will result can be safely anticipated. Almost the same conclusion as to modes of proceeding for relief of the distressed poor was arrived at on Thursday evening at the Parkes Museum of Hygiene, when Mr. H. A. Darbishire delivered an address on the present and future condition of the London poor and their dwellings. After some discussion had taken place on the subject of the paper, it was resolved to form a committee of members of the society to inquire as to the sanitary condition of the poor of the metropolis; so that unless amalgamation of this committee with the Mansion House Council is effected two independent bodies will be at work in the same connection. Possibly co-operation between the two may be arranged; and should this be so, greater good will accrue than from ununited endeavours.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 20.3 per 1,000 of their aggregate population. The death-rates in the several towns were:—Norwich, Bradford 15; Portsmouth, Leicester 16; Preston, Derby, Wolverhampton, Bristol, Hull 17; Edinburgh, Blackburn, Bolton, Birkenhead 18; Sunderland, Oldham, Nottingham, Cardiff, Birmingham, Halifax, London 19; Plymouth 20; Huddersfield, Salford 21; Glasgow, Liverpool 22; Brighton 23; Dublin, Sheffield, Newcastle-on-Tyne 24; Leeds 25; Manchester 26.

The International Health Exhibition.

EXHIBITORS in the section of the coming International Health Exhibition devoted to Dwelling-house Construction and Fitting, are informed by a memorandum from the sub-committee, that it is desired to show actual buildings erected ready for use, and to have them fitted with furniture and appointments of the designs to be exhibited in new and improved forms. Arrangements will be facilitated between various classes of exhibitors in this connection, with a view to bring about conjoint action, and thus ensure successful fulfilment of the committee's intentions, and it is further suggested that special interest would attach to exhibition side by side of harmless and harmful materials, as, e.g., arsenical and other paper hangings, badly-drained and scientifically-drained houses, &c. In every way that seems likely to enhance the prospective success of the Exhibition the executive is doing its best to promote a result equal to the sanguine expectations indulged. So far a vast amount of work has been accomplished, and the undertaking, in spite of its enormous magnitude, is already fully conceived in all details, and in many respects definite arrangements have been entered into. Both interest and energy have combined to make the Exhibition pre-eminent in its characters, and there can be little doubt that it will be an important event in the history of personal and domestic hygiene.

Men of the Times.

THE Biography of the Great, published yearly, under the title of "Men of the Time," would seem to be compiled by some one whose purview of men of science and medicine is rather strabismic. The Editor, as is pointed out by a medical contemporary, does not consider Lister, Savory, W. B. Carpenter, Michael Foster, Quain, Bristowe, Barnes, or Playfair, worthy of being named as Britishers, and to show impartiality, he omits all mention of Charcot, Donders, Billroth and Ziemssen, and many other continentals of the same calibre. From the entire profession in Ireland, medical, surgical, and scientific, he culls just two representatives, Drs. Mapother and George Johnston.

The Asclepiad.

UNDER the title of *The Asclepiad*, Dr. B. W. Richardson, F.R.S., has just published the first number of a quarterly serial devoted to presenting the results of his own independent researches before the profession. So laborious a work must needs task even an enthusiastic avowed like Dr. Richardson; but none the less we feel assured that each instalment of the publication will be found to well maintain the lofty reputation he has achieved by his invaluable contributions to the science of medicine. Among other interesting communications, No. 1 of *The Asclepiad* contains the full text of Dr. Richardson's Glasgow address on "Felicity as a Sanitary Research," and a carefully-written and important paper on "Morphia Habitues and their Treatment," being an essay recently read to the Medical Society of London. A brief description of a practical clinical note-book will be of great practical assistance to many readers, and is especially deserving of attention. This number is, indeed, full of most instructive and interesting matter, and the profession

may be much congratulated on Dr. Richardson's determination to continue the series.

A Proposed Sanatorium for Ventnor.

ANY proposal to establish sanatoria in suitable spots at home should receive encouragement and support from the medical profession for several reasons, but principally because patients are not called upon to undertake exhausting, and sometimes perilous journeys to foreign health resorts, and because, also, the same treatment whereby they may have become convalescent can be continued, if necessary, under the personal supervision of the medical attendant. Recently the "Mont Dore" was started at Bournemouth, and although the building is not quite ready for occupation on account of its gigantic proportions, we understand that about three-fourths of the capital was readily subscribed, and that its promoters are confident of success so soon as it is out of the builders' hands. That Bournemouth is most favourably situated for such an establishment is admitted on all sides, and we wish its "Mont Dore" the prosperity anticipated. Another favourite spot on the South Coast is about to put forward a claim for a similar undertaking, and the residence of the late Dr. Pusey, near Ventnor, Isle of Wight, has been selected as a commencement. The house is charmingly situated in delightful grounds, from which issues a chalybeate spring of known value. It is proposed to alter and enlarge the existing building from time to time as necessity arises. Like Bournemouth, Ventnor undeniably possesses the essential characteristics of a health resort in its highest sense, and with the strong medical council of some thirty members, which we find on the prospectus of the company, there ought to be no doubt of its ultimate success.

What Determines Sex in Offspring?

OWING to the observations which have been made by cattle breeders and others, upon this question, of late, an increased and increasing interest is shown in the subject. From the earliest times, it has exercised a certain fascination over the minds of the leading men, who have devoted themselves to the study and solution of physiological problems. Amongst these names may be noted those of Plato, Hippocrates, Anaxagoras, Parmenides, Erasmus Darwin, Galen, Dr. Harvey, V. de Graefe, Zieuenhooch, Malpighi, Swammerdam, Haller, Blumenbach, Koelreuter, Buffon, Dumas, Costi, Bischoff, Barry, Flint, Charles Darwin, and many others of more recent date.

For a full inquisition into their various views, we would refer those amongst our readers who may take a special interest in this problem, to a very interesting and readable paper, that appeared in the November (1883) number of the *Detroit Lancet*, p. 200, from the pen of P. H. Clarke, M.D., Ashland, Ohio, who seems to have made it a special study.

At the close of this paper, he records, as the result of his review of a large number of theories, facts, and observations, the following conclusions: "1st. That the conjoint union of the sperm and germ cells is impregnation, conception, fecundation, under whatever term used. 2nd. That this union is a complete coalescence, particle by particle, not simply a joining of cells, but a complete union of mole-

cule with molecule forming an embryo *de novo*, which in the conjunction, the two primary cells are so effectually lost in the combination that not a single original characteristic of either is left. 3rd. That there is no known law of sexuality that can convey the distinction of sex, and that all theories endorsing this hypothesis, are based on mere conjecture. 4th. That the experiments in sex determination fully prove that sex is produced at will, and therefore is a condition of extrinsic force engrafted subsequent to the union of the sperm and germ cells. 5th. That this determining force depends upon nutrition and other conditions independent of sexual potency. 6th. That experiments in comparative physiology demonstrate these and such are entirely reliable. 7th. That although parthogenesis is a modification of the laws of generation in the higher orders of animals, yet the universality of its expression in the lower orders shows conclusively its determining force. 8th. That an important source of sexual determination is nutritive as far as ovum development is concerned, that is, when the force becomes partially exhausted, the result is the production of males; when the ovum is in the maximum of sexual potency, then the product is invariably females. Lastly, that the profession should drop all the exploded theories of sexuality, else stock growers by their experimentations, will develop the true theory of sex determination at the expense of the medical capacity of the world." The subject is one that affords an ample field for further observation and study. A careful and methodical accumulation of well observed, and well authenticated, facts, can be the only true foundation on which reliable conclusions can be based. Some of the points noted, find corroboration in one's own experience, and gives one a new interest in facts connected with pregnancy, lifting that portion of a medical practitioner's work out of the rut of an uninteresting routine. For instance, it will be a point worth noting, whether there is truth in this observation of Dr. Joseph A. Mudd, (*Medical Record*), that, if a labour is postponed beyond the time calculated, as the full term of gestation, the child will be a male; if it takes place some time before it is expected, then it will be a female. Care of course must be exercised in calculating the exact time.

The Copenhagen Meeting of the International Congress.

THE International Medical Congress will be held in Copenhagen on August 10th. Many valuable communications have been promised, and nearly four hundred non-Scandinavian colleagues have already announced their intention to attend. From France, amongst others, come Pasteur, Paul Bert, Ranvier, Charcot, Verneuil, Cornil, Hayem, Malassez, Chauveau, Ollier, Tripier, Lepin. From Italy—Bizzozero, Mozza, Galgi, Peromonte, Novaro, Raymond, Giacomo, Baccelli, Tomasi-Crudeli. From Holland—Donders, Guye, Engelmann, Heinsius. From Germany—Virchow, Ludwig, Esmarch, Volkmann, His, Braune, Kronecker, Munk, Kühne, Heidenhain, Vogt, Bernstein, Grohe. The most eminent medical men of Sweden and Norway have become members of the various committees of organisation.

The Sources of Animal Heat and Muscular Power.

PROFESSOR BUNGE, of Dorpat, has lately published in the *Zeitschr. f. Physiol. Chemie* (Bd. 8, S. 48-59) the results of experiments carried out by him with a view of throwing light upon the question—What are the immediate sources of heat and of muscular activity within the organism?—recent views inclining to the belief that muscular power is principally due to the splitting up of food material previous to oxydation, and that body heat is mainly due to the oxydising process itself.

It occurred to him that if this view were the correct one, it should lead to the expectation that those animals that require absolutely no body heat of their own would have the least need for oxygen. Such animals are the entozoa of warm-blooded animals, which pass their lives in an unvarying and moderately high temperature, within the bodies of other animals. He selected the *ascaris mystax* of the cat, an entozoon that is distinguished by very active movements, as one suitable for experiment. He first ascertained that these ascarides could be kept alive and in an active condition in a solution of common salt (1 per cent.) and carbonate of soda (1 per cent.), maintained at a temperature of 38 C. (100-2 F.) for a period of from eight to ten days. The next step was to extract the oxygen from the water as completely as possible. This was done, with the result that the entozoa continued to live and move actively in the solution thus freed from oxygen for from three to five days, the animals not dying till the fifth or sixth day. He does not contend that the ascarides can live without oxygen; the experiments rather prove the contrary, as in solution not deprived of it they lived generally eight to ten days, and sometimes as long as fifteen; but he does claim that the need of oxygen of these entozoa is much less than that of other animals.

The experiments thus throw some light on the sources of muscular power in animals, as in these animals experimented on they cannot exclusively reside in the process of oxydation, for the movements were just as lively and continued for days in a medium deprived as completely as possible of its oxygen. They must rather be sought in the splitting up process that takes place in the food.

Elimination of Mercury During and After its Cutaneous Employment.

SINCE the year 1881, Dr. Schuster, of Aix-la-Chapelle (*Journal of Venereal Diseases*), has made more than 100 examinations regarding the elimination of mercury in syphilitics, who were either still under treatment by mercurial inunction, or had been so treated from one to twelve years. Most of the patients had used mercurial ointment for the inunctions; in a few, where examination did not reveal traces of mercury in the urine, the drug was employed subcutaneously. In the urine, the writer states that he found mercury in small, rarely in large quantities, and not only during, but also some weeks after the mercurial treatment. Often, however, the mercury was not found in the urine, either during or after the treatment. He concludes:—1. Mercury is irregularly eliminated by the urine—a result already pointed out by Vajda and Paschke. 2.

The mercury introduced by inunction either—(a) Remains stored up in the organism; or else—(b) It is excreted by some other channel. Schuster proceeded to the examination of the fæces, and found that mercury was *always present in large quantities*. The result of the forty faecal examinations was as follows:—Mercury was found—1. In relatively large quantities during the course of inunctions (earliest test ten days after beginning of treatment). 2. Mercury was found in the fæces for 5½ months after the end of the course. Examinations made every ten to fourteen days. Mercury was found in the fæces in all the cases in which it was found in the urine; *per contra*, it was often absent from the urine when present in the fæces. After prolonged courses of inunction, mercury was found in the fæces in such large amounts that it could have been determined quantitatively. This second series of experiments shows clearly:—1. The elimination of mercury by the fæces is regular, continuous. 2. The elimination of mercury after more extensive courses of inunction, say from thirty to forty-five days, is completed in six months. 3. Accordingly, persistence of mercury in the system does not occur.

The Berlin Polyclinic.

THE Berlin Polyclinic, which celebrated its first anniversary in November of last year, was attended by more than two hundred medical men between this date and that of its foundation. The School possesses two laboratories, chemical and histological, where original investigations may be carried out, and a special laboratory for the study of bacterial pathology will be opened soon. Classes are held in several special subjects, and the instruction is practical throughout. Dr. Loewe is surgeon-general of the School.

The Medical Curriculum in Germany.

A RECENT decree of the German Federal Council relating to the education of medical students has given rise to a good deal of discussion amongst those concerned. A clause that may well be the cause of feelings of not a little discontent is to the effect that only *under exceptional circumstances* will medical students be permitted to reckon as part of the recognised course any studies carried on at any other than a university of the German Empire. As there are at present a great number of German students at Vienna and Prague, this decree is felt as a great and needless curtailment of their privileges. The German students of the latter city have petitioned their Government in favour of a return to the old regulations, which gave the same privileges to Austrian and Swiss universities as to those of the Empire.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 29, Bombay 28, Madras 41, Paris 25, Geneva 23, Brussels 23, Amsterdam 32, Rotterdam 27, The Hague 28, Copenhagen 19, Stockholm 21, Christiania 23, St. Petersburg 39, Berlin 23, Hamburg 29, Dresden 34, Breslau 31, Munich 28, Vienna 24, Prague 39, Buda-Pesth 31, Trieste 40, Turin 33, Venice 29, Lisbon 36, New York 22, Brooklyn 20, Philadelphia 24, and Baltimore 19.

Legacies to Medical Charities.

By the death of Mrs. Tait, of York Terrace, Regent's Park, the following Liverpool hospitals become entitled, under the Carlyle bequest, to the sums specified:—Royal Infirmary, Lunatic Asylum, and Lock Hospital, £2,000 each; Royal Southern Hospital, £2,000; Northern Hospital, £2,000; North, South, and East Dispensaries, £2,000 each; Infirmary for Children, £2,000; Bootle Borough Hospital, £1,000; Consumption Hospital, £1,000; Eye and Ear Infirmary, £1,000. The following London hospitals are entitled to £2,000 each under the same bequest, viz.: St. George's Hospital, the Brompton Hospital for Consumption, and St. Mary's Hospital. Under the will of Miss Harriet Helena Mercy Barber, late of Kingston-upon-Thames, the Cancer Hospital, Brompton, and the Hospital for Consumption and Diseases of the Chest, Brompton, each receive a bequest of £300.

WESTON, whose start on a continuous walk of 5,000 miles, 50 miles per day, we chronicled about two months since, has now completed 3,300 miles of the projected journey on temperance principles. The last medical examination found him in superb health, and capable of prolonged strain, accident alone excepted.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

MORE THAN A CENTENARIAN.—We have frequently to record the deaths of centenarians in Scotland. Quite recently a fisherman named John Macdonald, in Lews, died at the advanced age of 105. He was blind for several years, but enjoyed excellent health, and his memory remained unimpaired to the last. His eldest son, who is also blind, resided with him, and he is above 70 years of age. There appears to have been no doubt as to the age of the deceased.

PRECEPT VERSUS PRACTICE.—At the fortnightly meeting of the Glasgow Town Council, in submitting his report, Dr. James B. Russell, the medical officer of health, stated that 8 cases of small-pox had been registered during the past fortnight. Dr. Russell went on to say that—"I report the occurrence of a case of small-pox in the Fever Hospital staff. It shows that, while criticising others as to vaccination, I have not succeeded in getting those under my direct control to enforce it systematically."

GLASGOW ROYAL INFIRMARY.—We understand that at a recent meeting of the directors of this institution some important alterations have been made in the rules under which physicians and surgeons to the hospital hold office. Henceforth no physician or surgeon will be eligible for reappointment for a longer period than ten successive years; and the appointments shall be made annually. This was the period during which these officials originally held office, being then compelled to work up into the superior position through the out-door department, and when the period was extended to fifteen years much disappointment was felt in the profession, as thus the chances of benefiting by the wide field of observation became extremely circumscribed. The directors have now acted justly to the profession; they are to be congratulated on having done so, and it is our firm conviction that they will have no cause to regret the adoption of so wise a step.

ROYAL DISPENSARY, EDINBURGH.—Dr. Littlejohn was last week elected Consulting Surgeon to this institution. The compliment is well deserved, for Dr. Littlejohn has always shown a deep interest in the welfare of this, the oldest dispensary in Edinburgh.

MORTALITY IN GLASGOW.—The death-rate in Glasgow for the week ending with Saturday, the 26th ult., was 23 per 1,000 per annum of the population, as compared with 26 in the previous week, and 30, 22, and 46 in the corresponding periods of 1883, 1882, and 1881 respectively.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 26th ult., was 83, and the death-rate 18 per 1,000. There were eighteen deaths under 1 year, and fourteen above 60, of which two were above 80 years. Diseases of the chest accounted for 40 deaths, and zymotic causes for 11, of which 1 was due to fever and 6 to measles, the intimations of these diseases for the week being 9 and 186 respectively.

GLASGOW LOCK HOSPITAL.—The annual general meeting of contributors and subscribers to the Glasgow Lock Hospital was held in the Religious Institution Rooms on the 28th ult. The report stated that during the last twelve months the admissions into the hospital numbered 347, with 30 in the wards at the close of the year.

ST. JOHN AMBULANCE ASSOCIATION IN SCOTLAND.—The influence and work of this excellent institution are gradually permeating through every part of the United Kingdom. A centre has just been formed at Dundee, of which the Earl of Strathmore has accepted the presidency. Here two important meetings were held on Friday and Saturday, attended by Mr. John Furley, Deputy Chairman of the London Committee. One meeting was for the general public, and the other for *employés* at manufactories and railways, police, firemen, &c. Sir Edward Perrott presented certificates to the Erith female and police classes on Saturday afternoon.

EDINBURGH UNIVERSITY.—The University Court met on Wednesday last to take into consideration the proposed alterations of Ordinance No. 5, in so far as regards attendance on the practical classes of Physiology, Pathology, and *Materia Medica*, &c., the result being that the said ordinance was finally amended and adopted as follows:—Sub-section 1.—The paragraph relative to practical midwifery to be deleted, and to be inserted in the form given below as a new sub-section, to be numbered 5. Sub-section 3, as altered by order of Her Majesty in Council, of date 29th June, 1878. The part of the sub-section following the words "at the laboratory of an hospital or dispensary" to be deleted, and the following to be substituted therefor:—"Under the instruction of a teacher recognised by the University Court under said sub-section 4 of section vi. of Ordinance No. 8, Edinburgh No. 3; or that he has been engaged by apprenticeship, for not less than two years, with a registered medical practitioner, or a member of the Pharmaceutical Society of Great Britain, or a member of the Chemists and Druggists' Association of Great Britain, in the *bona-fide* compounding and dispensing of drugs, and the preparation of their officinal, and other preparations for administration under his superintendence." The following sub-sections to be added:—5. That he has attended for at least three months the practice of a midwifery hospital, or that he has attended at least six cases of labour under the superintendence of a registered medical practitioner. 6. That he has attended, during courses of not less than fifty hours' instruction, classes of Practical Pathology and Practical Physiology in the University of Edinburgh, or in a University or school of medicine recognised by sub-sections

2 and 4 of section vi. of Ordinance No. 8, Edinburgh No. 3; or upon classes thereof conducted by a teacher recognised by the University Court under the said sub-section 4. At the same Court, Dr. Henry D. Littlejohn was appointed to be the additional Examiner in Medical Jurisprudence for five years from the 1st inst., but subject to annual re-appointment. On consideration of a minute of *Senatus*, it was resolved to recognise Mr. H. E. Clark, F.F.P.S., Glasgow, as a teacher of medicine in Glasgow, whose lectures and course of practical instruction in anatomy should qualify for graduation in Medicine in the University under Ordinance No. 8, section vi.

THE ROYAL EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—Last week the annual dinner of this Society was held at the Waterloo Hotel, where the *élite* of the profession of Edinburgh assembled to meet the Right Hon. the Lord Provost of Edinburgh, the Right Hon. Sir Lyon Playfair, the Presidents of the Colleges of Physicians and Surgeons, and other distinguished visitors. After dinner, the usual loyal and patriotic toasts having been honoured, the Chairman gave the toast of "The Royal Medical Society," thus asking his hearers to go back in imagination to a period of 150 years ago, when a small number of people met together in Edinburgh to discuss amongst themselves questions respecting suffering humanity of their day. That Society was short-lived, but before it passed away from the face of history, it had become the germ which, at a shortly subsequent period, was to produce this Society, under whose auspices they were now assembled. The toast, however, in which was concentrated the greatest amount of interest was that of "The Universities," to which Sir Lyon Playfair was to respond. That gentleman expressed his opinion that the Universities were safe enough in impending legislation, with the exception of St. Andrews, the oldest University in Scotland, which, he feared, might die rather from lack of material support than Parliamentary interference. Speaking of the Corporations, he deplored the differences and contending interests which existed between them and the Universities, which last year nearly paralysed the action of the Government, and if the Bill had then been proceeded with it would have slipped through according to English ideas, untempered by Scotch experience and need. Let them make their interests identical, and come to a compromise as to the differences that existed, and he would promise them that the Scotch representatives as a body would unite, and obtain the modifications in the Bill. He considered this common agreement most essential, and could readily be attained by a common union of interests. If (said Sir Lyon Playfair) Professor Crum Brown would throw his arms round the neck of the President of the College of Surgeons—(laughter)—and both acted in common, that would have great power in moulding the Bill next session. A few moderate men representing the Universities and the Corporations could soon settle a compromise of claims in a manner that would secure the best interests of medical education.

ARBROATH.—GIFT TO INFIRMARIES.—Mr. John Duncan, of Parkhill, near Arbroath, has intimated that it is his intention to devote a sum of about £300 to the Arbroath and Montrose Infirmarys—£150 to each—for the purpose of making some provision for patients on leaving the infirmary. The object would be to help poor patients after their discharge from the infirmary, in providing them with clothing or otherwise until they got work, as Mr. Duncan states he observed that in such cases, and without assistance of the kind, the benefits of the infirmary are often in a great measure thrown away. The directors of the Arbroath

Infirmiry, at whose quarterly meeting the intimation was made, expressed their thanks to Mr. Duncan for his considerate kindness.

IMPORTANT MEDICO-LEGAL CASE.

IS LOBELIA A POISON?

IMPORTANT TRIAL OF A "MEDICAL BOTANIST."

On Thursday, before Mr. Justice Watkin Williams, at the Old Bailey, James Wallis, of the "City Road Dispensary," 34 Bath Street, City Road, was tried for manslaughter of a woman named Sainsbury, by administering to her lobelia.

Mr. Poland and Mr. Mead represented the Public Prosecutor. The prisoner was defended by Mr. Montagu Williams and Mr. Lyons.

The formal evidence established the following short statement of facts:—On the 10th December, a man named John Bull went to prisoner's shop and stated that Mrs. Sainsbury (aged 44), who was his landlady, was exceedingly ill; that she had had medical attendance at several dispensaries for three months without finding relief; that she was weak and not able to get out; and that she was choked with phlegm; and that she thought that if prisoner gave her some stuff to get rid of the phlegm, she would be all right. The prisoner then gave Bull some powders and a plaster, and a bottle of medicine and some pills, saying that the medicine was an emetic. He wrote on the bottle, "A teaspoonful to two tablespoonfuls," but he told Bull that if she took the whole bottleful it would do her no harm. Bull took home the medicine, and Mrs. Sainsbury took about a tablespoonful of the contents of the bottle: in ten minutes she had diarrhoea, and subsequently fainted, and was dead upon the arrival of a doctor, half an hour afterwards. The remainder of the contents of the bottle was sent to Dr. Stevenson, of Guy's Hospital, and was found to consist of an acetic solution of lobelia. A coroner's inquest was held, and the prisoner was now charged with manslaughter on the coroner's inquisition.

Mr. John Lloyd Whitmarsh, Licentiate of the Royal College of Physicians, and in practice at Fulham Road, South Kensington, said that the deceased woman had been dead about half an hour when he was called to see her. She was cold and clammy, and covered with cold sweat. The pupils were dilated. He subsequently made a post-mortem examination, and found the right lung adhering to the walls of the chest. She had been suffering from chronic bronchitis; the left lung was very much contracted and diseased, in fact, almost gone; and there were also adhesions on that side; the liver was much congested; the brain was congested at the posterior portion; the inner coats of the stomach and the bowels were inflamed. Witness put in a jar a portion of the contents of the stomach for subsequent examination by Dr. Stevenson. Witness at first thought that the bottle contained hellebore, from its appearance and taste. The effect of hellebore would be almost the same as that of lobelia. He came to the conclusion that she died from an irritant poison acting as a depressant on the heart's action, causing fatal syncope. He knew the nature of lobelia; it was used as an emetic; he did not himself use it as an emetic; he used it frequently as an expectorant and an anti-spasmodic; he used the tincture, never the powder or seeds. Lobelia was an Indian tobacco, or herb. He used the tincture made from the seeds; a dose of the tincture would be from 10 to 30 drops; half a drachm, which would be 30 drops, would contain about 4 grains of the seeds. He should consider 28 grains a dangerous dose. If such a dose failed to act as an emetic, it would act as a depressant on the heart's action, bringing on faintness. The appearances of the corpse were consistent with the death.

Cross-examined by Mr. Montagu Williams: He had made a mistake in at first supposing that this medicine was hellebore. Hellebore was one of the forbidden poisons. There had been a good deal of discussion in medical works as to the properties of lobelia. He agreed with the following extract from Dr. Skelton's book:—"In some cases where there is necessity for a speedy action, as in cases of angina pectoris or neuralgia of the heart, give one or two doses of twenty drops." That would not be dangerous if it were watched. He would give thirty drops to a grown-up person. He should say that in cases of diarrhoea a drachm of the powdered herb and seed of lobelia would not be a proper dose. He would not take Dr. Skelton's book as an autho-

rity, although the author was a Licentiate in Medicine and Surgery of London, Edinburgh, and Glasgow.

Do you agree with this: "What is the form of the disease which we are called upon to treat must be the first consideration. If it is simple diarrhoea, prescribe lobelia (powdered herb and seed), one drachm; capsicum (powdered cayenne), ten grains; podophyllum peltatum (powdered mandrake), twenty grains." For diarrhoea would it be a dangerous prescription?—It would.

Listen to this extract from Dr. Elliotson: "Lobelia, in fact, is one of the most important articles in the materia medica. With many it acts as a charm. In ten or twenty minutes they will be perfectly relieved, so that all the other remedies used in asthma and other diseases of the respiratory organs are nothing to be compared to it." Do you agree with it?—Yes, in proper doses.

Re-examined: Several things not in the list were poisons. Lobelia was a poison. The fact of a drug not being in the prohibited list was not conclusive as to its not being a poison. Dr. Alfred Swayne Taylor was a great authority on poisons. The following was an extract from his work on the subject:—"Within the last few years there have been several inquests and trials for manslaughter in this country as the result of the improper administration of the leaves of the lobelia inflata by ignorant quacks calling themselves medical botanists and dealers in vegetable medicines. The medical evidence given on those trials showed that in large doses lobelia is a most noxious drug. From inquiries recently made, I have reason to believe that deaths from lobelia still frequently occur in the northern counties. The noxious medicine is taken in secrecy under the direction of quacks, and any death arising from it is either concealed or referred to other causes." The following was an extract from Woodman and Tidy on Forensic Medicine and Toxicology:—"Lobelia is imported from North America in the form of compressed oblong cakes, which are sent over by the Shaking Quakers of New Lebanon, and are principally used by the quack botanical doctors who revel in the ominous name of Coffinites. Coffinism is no innocent harmless system. Its absurd theory is that heat is life, and the want of heat disease; so cayenne pepper and lobelia are the two principal medicines of its professors, which they administer with no cautious or measured hand. Over and over again they assert what has over and over again been disproved—that lobelia cannot kill." He considered lobelia was a poison, and could kill.

Dr. Thos. Stevenson, Professor of Medical Jurisprudence at Guy's Hospital, deposed to having analysed the remainder of the contents of the bottle. It was an acetic solution of lobelia; it was very turbid, with a considerable deposit of the herb itself. He should judge that the deceased had taken about 1½ fluid ounces. The mixture was about 28 grains of the seed and leaves, mostly seeds, to the fluid ounce. The appearance of the body after death would be consistent with poisoning by lobelia. The stomach was reddened, congested; probably, if deceased had lived longer, it might have gone on to inflammation. It appeared as if some irritant had been given. Lobelia was an irritant. The acetic acid in which the lobelia was dissolved would also act as an irritant. From the account given of the mode of death and the post-mortem examination, it did not seem to him that death was caused by suffocation. Two tablespoonfuls of lobelia was not a proper dose. There would not be any particular harm in a teaspoonful. In his experience of the use of this drug it had been very dangerous. He had seen people suffering very great depression when they had not vomited. It was stated on very high authority some years ago that thousands of deaths had occurred from it up to that time in America. American works of authority spoke of it as a very potent medicine and a poison. The pills and powders also given to the deceased were harmless; the former were of capsicum—the powders contained cinnamon. The object of lobelia was to cause vomiting when given in large quantities, but it was never now so used by reputable medical practitioners; they had given it up on account of the danger attending its use in large doses.

The Police Inspector who arrested the prisoner said that at the time he made the following statement:—"I sent her lobelia, but it is a lie to say it killed her or that it is poison. My wife has taken double the quantity. That fool of a doctor who gave evidence yesterday knows nothing about it. The medical science of this country is a fraud. She died of

her ailments. God made the world, and supplied it with herbs for every complaint, but those fools of doctors do not know how to use them. I do. They are enemies of mine."

Mr. Montagu Williams, having addressed the jury, called the following witnesses for the defence:—

Mr. Thomas Stowell, M.R.C.S., of 8 Church Street, Brighton, said he had been in practice for over thirty years. During the whole of that time he had been in the daily habit of using and prescribing lobelia inflata. He had taken it himself in drachm doses. Emphatically it was not a poison. It was an invaluable medicine; there was nothing like it in the whole of the *materia medica*. To a very delicate child and in a dangerous condition he would give a teaspoonful of it in the syrup every three hours. Lobelia was a tonic, an expectorant, a sudorific, and a most valuable emetic. Mr. Bravo would have been alive now if he had used it instead of antimony. When the Poisons Bill was before the House of Commons, guinea-pigs were obtained from Covent Garden Market, and experiments were made with this so-called poison; but the guinea-pigs would not die from it; they grew fat instead. If lobelia did not act as an emetic, it would be perfectly harmless; it would pass through the body as a gentle aperient; it would not have a depressant effect on the heart. However large the dose, lobelia could not be deleterious.

Mr. Justice Williams: Do you mean to say that half a pound of it would not be?—Well, it did not kill the guinea-pigs when we fed them on it; they only got fat on it.

Examination continued: The following extract from Woodman and Tidy was put to the witness:—"In poisonous doses the symptoms closely resemble those of tobacco; there is severe vomiting, with intense depression and prostration, headache, giddiness, tremor, and often insensibility, the patient becomes bathed in cold sweats, the pupil is contracted, diarrhoea and dysuria are not uncommon, the pulse is generally intermittent, and convulsions usher in death. But, on the contrary, the patient often gets well, and the reason is quite obvious; so long as vomiting is produced all will be right." He denied that under any circumstances lobelia could have the effect stated, or could cause death; that was copied from other works written in malice.

Is it as harmless as castor oil; for instance, would you allow the head of a family to have it in the house for ordinary consumption?—If there be a number of children suffering from the croup, I should say always keep it in the house, it is one of the best remedies for croup to be found in all creation.

Mr. Charles Lakin, of Leicester, Licentiate of the Royal College of Physicians Edinburgh, and of Glasgow Faculty: I have been in practice for eleven years, and during that time have been in the habit of using and prescribing lobelia; lobelia was a tonic, a sudorific, an expectorant, and one of the most valuable emetics known to the British Pharmacopoeia. I have given as much as 60 grains; 28 grains is not a dangerous dose as an emetic; it was not dangerous to be administered to the deceased; having regard to her condition, I do not believe it accelerated her death.

Cross-examined: The cause of death was failure of the heart's action; lobelia had nothing to do with it. Dr. Taylor is an eminent authority on poisons.

Is there any such thing as an excessive dose, so as to be dangerous?—I should say yes, on the same principle that you may take such a large quantity of common salt that you may inflame the stomach and cause death. I have known a patient take 240 grains at a dose.

Several herbalists next gave evidence in defendant's support, and which it is unnecessary to repeat. Finally the judge intimated his belief in the strength of these statements, and the case went to the jury, who returned a verdict of "Not guilty," adding the following rider:—

"We recommend that the prisoner should be more cautious in the use of disputed drugs."

Correspondence.

COWELL ON THE TREATMENT OF CATARACT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your review of Mr. Cowell's "Lectures on Cataract" you quote that he does not believe "that cataractous disease can be amenable to medical treatment." You, however, wisely, in my opinion, withhold your assent to his

sweeping proposition, and, as I have had experience of a case which certainly would show that there are exceptions to his rule, it will afford me pleasure if you give insertion to the following facts:—

When I was civil surgeon, Hyderabad, Scinde, some thirteen years ago, there passed under my treatment a Mr. Mendez, head accountant of the District Treasury, who had been suffering from double capsular cataract, and was about to be operated upon by Dr. H., ere he became a Professor in the Bombay University. I had some slight experience in cataract operations, and the results were not at all satisfactory in a climate and country with great glare and heat, and where fever is excited by the slightest constitutional disturbance. Scinde is like Egypt in these respects. I subjected my patient to treatment with Fowler's solution of iodide of potassium and tincture of larch internally, applying blisters to his temples, kept open by diluted red iodide of mercury ointment, and dilating his pupils twice a week with extract of belladonna and contracting them by dropping *vinum opii* into the eyes three or four mornings in the week. I tried rubbing an extract of calabar bean over the lids and brows, but my great forte was in enjoining that blue spectacles should be worn, and on the day after the belladonna was used, that they should be taken away and the eyes exposed to the glare for a short time frequently in the day. My object was to contract and dilate intensely and often the pupil, thus setting up a frictional movement as close as possible to the seat of abnormal tissue, and to promote the circulation in the ciliary vessels from which the lens derives support. After a little more than two months, Mr. Mendez returned to his desk with transparent lens and good eyes.

I tried this treatment with a lady who was suffering from cataract in one eye. The lens was perfectly and apparently opaque throughout its substance, and hence there was no benefit derived. To have confidence in the treatment I would require that the opacity should be superficial, uneven, and that belladonna should be attended with improvement. There was no history of diabetes, syphilis, or rheumatism in the case cited.

I am, &c.,

JOHN ROCHE, M.D.,
Retired, Bombay Army.

[The etiology of the cataractous disease is by no means exhausted, and Dr. Roche is to be congratulated on the success which has already attended a departure from the teaching of modern ophthalmology. Since the synthesis of diabetic cataract was fairly worked out, no attempt whatever has been made in a direction which seemed to open a new field for the ultimate successful treatment of other forms of cataract.—Ed.]

THE DEMORALISING AND PAUPERISING INFLUENCES OF HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your article of the 30th ult. on the demoralising influence of the *gratis-advice* system at our hospitals will meet the approval of medical men who earnestly desire to live a life of truth and honesty. True civilisation has been, and is, best promoted by the mass of common mortals faithfully doing their "daily task;" therefore it is far from being a small matter that the relations of the medical profession to the masses should be honourable and just. Excepting the priestly office, no class of men influence contemporary society more than do medical men; and not contemporary society only, but, in so far as they advance science and knowledge, they do some part toward the more rapid evolution of happier and better times and states. Therefore, as the battle for Truth is won, not by great speeches and great noise, but by each man doing his duty in his own humble sphere, so institutions have their part to play in their own greater circle.

But it is possible for our public institutions to be honourably administered. Here, in Plymouth, the Public Dispensary has instituted an "investigation committee:" every subscriber's ticket issued is submitted to this committee, and is by them cancelled if they consider the applicant to be in circumstances able to join a provident dispensary. A provident branch is attached to the institution, which they can at

once join, or they can join any of the other provident dispensaries in the town; but they are debarred from the privileges of the "charitable" side. Subscribers whose tickets are thus cancelled do not lose their rights, as they are supplied with new tickets exactly replacing those cancelled.

Thus the institution is helping, not to lower, but to elevate, the people; whilst the medical staff know and feel that every case which comes before them is justly deserving their labour and skill. I assure you, Sir, that it is a very great joy and privilege to seek to expend one's utmost power in the work, because it is felt that the work is thoroughly honest and good.

What one institution can do successfully, others may also; and there can be no doubt that, if the *gratis-advice* system throughout the country were honestly administered, that a very great number of pure streams would be created for the comfort and good of man, and lending, too, their power in creating a happier and better future.

Yours, &c.,

WILLIAM H. PEARSE, M.D.

Plymouth, Feb. 3, 1884.

THE CONJOINT EXAMINATION SCHEMES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In my letter on the above subject I find that I have been led into an error with regard to the statement of the *life* tenure of office of the examiners of the Royal College of Surgeons of Edinburgh. The examiners are elected annually by the Fellows. I therefore hasten to rectify the mistake, and regret that I should have been led into error on the subject.

I am, Sir, yours, &c.,

Edinburgh, Feb. 4, 1884.

H. AUBREY HUSBAND.

SIR WILLIAM THOMSON has had a fresh honour conferred upon him, the Emperor of Germany having enrolled him among the Knights of the Order for Science and Art.

PASS LISTS.

Royal College of Physicians of London.—The following candidates, having passed the necessary examinations for the diploma, were admitted Members on Thursday, January 31st:—

Acland, Theodore Dyke, M.D. Oxon., 79 Lambeth Palace Road, S.E.
 Barra, Alfred George, M.D. Edinburgh, Leeds.
 Beston, William Burns, M.D. St. Andrew's, Bath.
 Branfoot, Henry Seymour, M.B. Lond., Brighton.
 Buxton, Dudley Wilmot, M.D. Lond., 99 Gower Street, W.C.
 Campbell, Harry, M.B. Lond., 40 Keppel Street, W.C.
 Hebbert, Charles Alfred, L.R.C.P., Westminster Hospital, S.W.
 Smith, Robert Percy, M.D. Lond., St. Thomas's Hospital, S.E.

The following candidates, having passed the necessary examinations, were admitted Licentiates on Thursday, January 31st:—

Appleford, Stephen Herbert, 16 Finsbury Circus, E.C.
 Armitage, Edward Harris, 23 Brook Street, W.
 Beebe, Charles Edward, 84 Cambridge Street, S.W.
 Blackland, Walter, 128 Victoria Park Road, E.
 Blower, Bernard, 119 Shaw Street, Liverpool.
 Branthwaite, Robert Welsh, Infirmary, Macclesfield.
 Brown, Edwin Harold, Northampton.
 Burroughs, Leopold, Manor Villa, Lee, S.E.
 Chadwick, James Morley, Heywood, Manchester.
 Croft, Edward Octavius, 46 Mornington Road, N.W.
 Cummings, Harold Lytton, Dulwich, S.E.
 Dowling, Herbert Leopold, Hull.
 Dyer, Sidney Reginald, County Hospital, Huntingdon.
 Edwards, William Lloyd, 47 Spurstowe Road, E.
 Gooding, Matthew Richard, 67 Oakley Square, N.W.
 Graham, George Herbert, Thicket Road, S.E.
 Graham, William, M.B. Toronto, 86 Fleet Street, E.C.
 Green, Edwin Collier, 8 Telford Avenue, S.W.
 Harris, John William, 11 St. Thomas Terrace, S.E.
 Hart, Arthur Herbert, Edgbaston, Birmingham.
 Hington, Richard, Liskeard, Cornwall.
 Hubbard, Frederick Edmund, Kent Hospital, Canterbury.
 Hudson, Charles Leopold, Middlesex Hospital, W.
 Julian, Francis Herve, 14 All Saints Road, W.
 Knowles, Henry, Chapel Allerton, Leeds.

Littlewood, Harry, 22 Rutland Street, N.W.
 Loring, Jonathan Brown, M.D. Montreal, 53 Doughty Street, W.C.
 McConochie, Samuel Watson, M.B. Toronto, 75 Bancroft Road, E.
 McDonnell, William Campbell, Park House, Stoke Newington, N.
 Midland, Alfred Derwent, 10 Chester Place, W.
 Manders, Neville, Marlborough.
 Maurice, William James, Ipswich.
 Mills, Robert, Middlesex Hospital, W.
 Minns, Allan Glaisyer, Thetford.
 Muirhead, Michael Alexander, 33 Trinity Square, S.E.
 Neale, John Headley, Highfields, Leicester.
 Nuttall, Charles Dalley, 48 Bernard Street, W.C.
 Orchard, Alfred, Ashby-de-la-Zouch.
 Parry, Herbert Lloyd, 24 Canonbury Park North, N.
 Reld, George More, Sydney, New South Wales.
 Ross, Elsey Fairfax, 11 Duke Street, Portland Place, W.
 Rowland, John Jones, Aberystwith.
 Scott, Tom, Bere Regis.
 Sharples, William Henry, Castleton, Manchester.
 Sharpley, Edward, Louth.
 Sheldrake, Edwin Nodin, 23 Albion Street, W.
 Simoons, Joseph Auspicio, 24 Woburn Place, W.C.
 Spong, William, Cheltenham Road, S.W.
 Starr, William Henderson, 8 Roseford Terrace, W.
 Sutton, Henry Martyn, 59 Lambeth Palace Road, S.E.
 Thompson, Charles Herbert, 85 Lambeth Palace Road, S.E.
 Tilley, William James, 28 Shepherd's Bush Green, W.
 Tomson, Walter Bolton, St. Thomas's Hospital, S.E.
 Trevor, Edward Tull, 48 Queen's Gardens, W.
 Trotter, Dudley Cox, Caius College, Cambridge.
 Udale, Joseph James, 112 Uxbridge Road, W.
 Walton, Francis Fielder, Hull.
 Weller, Charles Joseph, 67 Colleshill Street, S.W.
 White, Ernest Alfred, 13 Blenheim Terrace, Leeds.
 Williams, Montagu W., North Eastern Hospital, Hackney Road, E.
 Withers, John Sheldon, St. Mary's Hospital, Manchester.
 Woods, Edward Robinson, M.B. Toronto, 75 Bancroft Road, E.

Royal College of Surgeons of England.—The following is a continuation of the lists of candidates for the Membership of this College published in our last:—

The following were admitted Members on Tuesday, January 29th:—

Bean, Charles Edward, L.S.A., Shepherd's Bush.
 Benson, Christopher Richmond, L.S.A., Clifton.
 Crocker, John Hedley, L.S.A., Gunnislake, Devon.
 Cummings, Harold Lytton, L.R.C.P. Edin., Dulwich.
 Edgelow, Herbert, Cambridge Street, Pimlico.
 Foley, Charles Nicholas, L.S.A., Denbigh Place.
 Holroyde, John, L.S.A., Ripponden, Yorkshire.
 Irvin, Frederick David, L.S.A., Longridge, near Preston.
 Julian, Francis Harvey, L.R.C.P. Lond., Queen's Park.
 Nuttall, Charles Dalley, L.R.C.P. Lond., Leicester.
 Parry, Herbert Lloyd, L.R.C.P. Lond., Canonbury Park North.
 Smith, John Charles, L.S.A., St. John's Wood.
 Whish, Martin Samuel, L.S.A., Granby Street.

The following were admitted Members on Wednesday, Jan. 30th:—

Armitage, Edward Harris, L.R.C.P. Lond., Brook Street.
 Clarke, Charles Frederick, Plumstead.
 Dodd, Arthur Herbert, L.S.A., Petherton Road.
 Gordon, Thomas Eliash, M.B. Durham, Gower, Swansea.
 Mills, Robert, L.S.A., Northampton.
 Minns, Allan Glaisyer, L.R.C.P. Lond., Thetford, Norfolk.
 Opie, Edward Augustus, M.B. Durham, Plymouth.
 Rowlands, William, L.R.C.P. Lond., Liverpool.
 Scott, Tom, L.R.C.P. Lond., Bere Regis, Wareham.
 Stables, Alexander, M.B., C.M. Edin., Nairn, N.B.
 Stott, Hugh, L.S.A., Uxbridge Road.
 Webster, Alfred George, Huddersfield.

Of the 196 candidates examined during the past and present week, 85 passed to the satisfaction of the Court and obtained their diplomas; 30 passed in Surgery, and when qualified in Medicine will be admitted Members; the remaining 81 failed to reach the required standard and were referred.

Hunterian Society.—The following is the list of office-bearers elected for the current year:—President: Dr. Robert Fowler. Vice-Presidents: Dr. Galabin, Mr. Clement Lucas, Dr. Major Greenwood, Mr. W. C. Toulmin. Treasurer: Dr. Fotherby. Trustees: Dr. Fotherby, Mr. D. De Berdt Hovel. Librarian: Dr. Burchell. Orator: Mr. James E. Adams. Secretaries: Dr. Herman, Mr. Charters J. Symonds. Council: Mr. M. Brownfield, Mr. F. M. Corner, Mr. E. Dukes, Mr. T. R. Fendick, Dr. E. G. Gilbert, Mr. P. Y. Gowlan, Dr. Talbot King, Dr. Rasch, Mr. H. A. Reeves, Mr. W. Rivington, Mr. G. J. B. Stevens, Mr. R. G. Tatham.

University of Cambridge.—The following candidates having passed the necessary examinations, and conformed to the rules of the University have received the degree of M.B. Cantab.:—G. E. Crallan, M.A., Emmanuel College, on January 9th; S. T. Salter, B.A., Emmanuel College, on January 24th; J. H. Lilley, B.A., St. John's College, on January 25th; R. D. Brinton, B.A., Downing College, on January 25th.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean and flat after it has passed through the post.

MR. GEORGE WALPOLE (Clifford).—Thanks for offer, but we cannot afford space for *verbatim* report.

DR. J. P.—Dr. Hack Tuke's "Chapters in the History of the Insane in the British Isles" has not yet been received for review.

MR. W. W. K. (Norwich).—Quite full at the present time, but will bear the matter in mind.

DR. WILSON.—An announcement of the "Swiney Prize" will be found at page 108 of our last issue. Although a committee of the Royal College of Physicians act jointly as adjudicators with the Society of Arts, competition is not necessarily confined to members of the medical profession.

ARCHIVES D'OPHTHALMOLOGIE.—C. D. is informed that the "Archives" is published by Adrien Delahaye, of the Place de l'Ecole de Médecine, Paris, at irregular intervals, usually every two months. The agents in this country are Messrs. Baillière, Tindall, and Cox, 20 King William St., Strand, London. The subscription is, we believe, £1 is. a year.

DR. S. MARTIN.—We have already replied in the negative.

DR. SIMPSON.—The only successful method of treating such growths in the larynx is by excision. Caution will not suffice for their removal.

MR. CARPENTER.—The prospects of the Bill are thought to be very encouraging; but until the nature and fury of the storms it will have to weather can be estimated it would be rash to anticipate the final result. You are right in your surmise respecting the Register.

AMERICAN.—An American M.D. cannot legally practise medicine in this country. He may, however, if willing to do so, present himself for examination at any of several corporations, e.g., the Royal College of Physicians of London, Dublin, or Edinburgh, and, if successful, he can then register his name as that of a duly qualified practitioner. From what we know of your school, we should think that, after six months' work, you might obtain an English qualification.

THE ROGERS TESTIMONIAL FUND. (ELEVENTH LIST.)

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The following additional subscriptions have been received since the announcement in last week's number of the *Medical Press*.

Yours, &c.,

J. WICKHAM BARNES, Hon. Sec.

Poor-law Medical Officers' Association,
8 Bolt Court, Fleet Street, London, January 23, 1884.

Jas. Cornwall, Esq. .. £1 1 0	M. Partridge, Esq. .. £0 10 6
D. B. Bolding, Esq. .. 1 1 0	Jno. Davies, Esq. .. 0 10 6
A. A. Jackson, Esq. .. 1 1 0	F. Haward, Esq. .. 0 10 0
W. Pearse, Esq. .. 1 1 0	Dr. J. Woodman .. 0 5 0

R. M. P.—Rarity among diseases, after all, a very comparative term, and will be settled by the amount of experience of practitioners individually. We should not be disposed to regard locomotor ataxy as a very rare complaint. Certainly we see a considerable number in the course of each year.

MR. ANDREWS.—The publication from which you quote is merely intended to advertise its editor, whose qualification is not registrable in this country, and concerning whose professional attainments we have no means of judging favourably. The association of names is an insult to the scientific physician.

J. M. H.—The Secretary of the Royal College of Surgeons of England is the authority to whom the application should be addressed.

A PICTURE SLIGHTLY ALTERED.—The *Cincinnati Lancet and Clinic* considers that "Faith," which is generally portrayed as a female figure clinging to a wave-beaten rock, would be better personified by the figure of a bald-headed man with a bottle of patent hair-restorer.

DR. FRANCISCO TORRES (Lisbon) will please receive our best thanks for his note and enclosure.

MR. JAS. ROBERTSON (Royal College of Surgeons of Edinburgh)—Your communication came to hand as we were at press; it shall appear in our next.

DR. KIDD (Dublin).—Your letter, on account of its length, is unfortunately crowded out of present number.

MR. HINTON (Wigan).—We have directed our publisher to forward you the illustration.

Meetings of the Societies.

WEDNESDAY, FEBRUARY 6TH.

LONDON HOSPITAL.—At 2.45 p.m., Emeritus Professor Jonathan

Hutchinson will commence a course of Six Lectures, the first being On Natural Groups of Skin Diseases.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Parker, On Mammalian Descent.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Dr. Matthews Duncan will show Dr. Auvar's Rest.—Specimens will be shown by Dr. Galabin and Dr. Horrocks.—Mr. Alban Doran, On the Relation of Prolapse of the Vagina to Hernia, illustrated by two Pedigrees.—Annual Meeting: The President (Dr. Gervie) will deliver the Annual Address.

THURSDAY, FEBRUARY 7TH.

ACADEMY OF MEDICINE IN IRELAND.—The Sub-Section of Anatomy and Physiology will meet at 8 o'clock.

HARVEIAN SOCIETY.—At 8.30 p.m., Mr. Edmund Owen, On a Case of Sub-Periosteal Hemorrhage in a Child suffering from Scurvy (Acute Rickets).—Mr. Noble Smith, On Deformities of the Fingers and Toes.

FRIDAY, FEBRUARY 8TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Parker, On Mammalian Descent.

ROYAL INSTITUTION.—At 8 p.m., Mr. G. J. Romanes, On the Darwinian Theory of Instinct.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Mr. A. Pearce Gould, On Obliterative Arteritis accompanied by Gangrene.—Dr. Hadden, On Obliterative Arteritis ending in Recovery.—Dr. Burney Yeo, On Primary Syphilis, with Acute Pyrexia.—Dr. Mansel Pleydell, On Thrombosis of the Vena Cava.—Living Specimens: Keloid on Chest, Dr. Badcliffe Crocker; Acne Varioliformis, Dr. Stephen Mackenzie.

ACADEMY OF MEDICINE IN IRELAND.—The Surgical Section will meet at 8 p.m.

SATURDAY, FEBRUARY 9TH.

ROYAL INSTITUTION.—At 8 p.m., Professor Morley, On Life and Literature under Charles I.

Vacancies.

Chorley Dispensary.—House Surgeon and Apothecary. Salary, £180. Applications to the Secretary before February 20.

City of Ely Dispensary.—Surgeon-in-Ordinary and Dispenser. Salary, £200. Applications to the Hon. Sec. by February 18.

Hospital for Consumption and Diseases of the Chest.—Resident Clinical Assistant. Applications to the Secretary by February 18.

Manchester Royal Infirmary.—A Second House Physician, a Fourth House Surgeon. Applications to the Chairman of the Medical Board immediately.

Nottingham Borough Asylum.—Assistant Medical Officer. Salary £100, with board, &c. Applications to the Medical Superintendent by February 18.

Wolverhampton and Staffordshire General Hospital, Wolverhampton.—House Physician. Salary, £100, with board, &c. Applications to the Chairman of the Medical Committee, on or before Feb. 8th.

Appointments.

GAMGEE, A., M.D., F.R.S., Physician to the Manchester Hospital for Consumption and Diseases of the Throat.

GREENWOOD, C. D., M.R.C.S., Medical Officer for the Yoxall District of the Lichfield Union.

HUDSON, C. L., L.R.C.P. Lond., M.R.C.S., Resident Physician's Assistant to the Middlesex Hospital.

HUBBY, E. L., House Physician to Charing Cross Hospital.

KING, A., M.B., C.M. Ed., Medical Officer for the Aspley Guise District of the Woburn Union.

LUCAS, A., M.R.C.S., Medical Officer to the Workhouse, Woburn Union.

MACDOWELL, C. W., M.D.T.C.D., F.R.C.S.I., Medical Officer to the Carlou Workhouse and Fever Hospital.

MEEHAN, N. J., L.R.C.P. Ed., L.R.C.S.I., Medical Officer to the New Ross Union Dispensary.

MOLONY, F., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the Porlock District of the Williton Union.

MOLYNEUX, J. F., M.R.C.S., F.R.C.P. Ed., House Surgeon to Charing Cross Hospital.

Births.

BROWNRIIG.—January 25, at Hill House, Gravesend, the wife of J. Annesley Brownrigg, M.A., M.D., of a daughter.

BUSHE.—February 1, at Dilkusa, Lucknow, the wife of Surgeon-Major Bushe, M.A., A.M.D., of a daughter.

HARRIS.—January 28, at Prince Town, Dartmoor, the wife of H. W. D. Harris, M.R.C.S., of a son.

PALMER.—February 1, at Erchfont, Devizes, the wife of F. W. Palmer, L.R.C.P. Ed., of a daughter.

TREWMAN.—January 28, at Treghothan, Fareham, Hants, the wife of Surgeon George T. Trewman, A.M.D., of a son.

Deaths.

COFFIN.—January 12 at Aiken, South Carolina, Amory Coffin, M.D.

HARLEY.—January 27, at his residence, The Lawn, Haverstock Hill, Thomas Harley, M.R.C.S., aged 65.

POOOCK.—At Mackay, Brisbane, from congestion of the lungs, after a short illness, Edward William Pooock, M.R.C.S., aged 38.

SINCLAIR.—January 23, at Ely, Cambridgeshire, George Murray Sinclair, L.R.C.P. Ed., aged 44.

THOMSON.—January 29, at Montrose House, Oldham, Alexander Thomson, F.R.C.S., J.P., aged 63.

WOOD.—January 28, at Ennisakillen, after an illness of only a few hours, Surgeon-Major Thomas Wood, A.M.D.

The Medical Press and Circular.

NATURAL GROUPS OF SKIN DISEASES. (a)

By JONATHAN HUTCHINSON, F.R.S.,

Emeritus Professor of Clinical Surgery at the London Hospital.

MR. HUTCHINSON commenced his lecture by explaining that it was his intention to deal on this occasion with those diseases which occur on the surface of the body, and about the nature of which it was very desirable that accurate knowledge should be possessed. It would be his endeavour to offer as clear an indication as possible of the grounds on which such affections ought to be grouped, especially since the number of artificial and inaccurate modes of classifying them in the past had introduced an amount of confusion concerning their actual nature which could not fail to be a source of perplexity and error. Many morbid phenomena presented by the skin had been dubbed with special names and given the importance of essential diseases, whereas they were in reality but attendants, and often of a very minor kind, on much larger diseases. The only reliable and efficient classification was that which was based on a recognition of causes and natural relationships, and which should associate together under a single heading those varieties of skin diseases which owed their origin to the same or a similar cause. It mattered not how far external appearances seemed to separate them provided their existence could be traced to essentially similar causes; they must be associated together as produced by a common agent.

In the same manner as botanists had come to discard the artificial classification of Linnaeus in favour of a system of grouping flowers founded on the apprehension of deeper and more scientific distinctions than the mere numbers of petals, stamens, &c., so must dermatologists deal with symptoms exhibited by the skin. Avoidance should be had of errors like that comparable to inclusion of rabbits and donkeys in one group because of length

of ear displayed by each, and which, spite of its apparent absurdity, is little worse than classification together of scabies and eczema as vesicular eruptions, or of Addison's disease as a form of cutaneous atrophy—an error contained in one of the most recent dermatological systems. In a word, *causes*, and not *names*, are to be accepted as governing arrangement of skin diseases into groups; and although the extent of our present knowledge permitting such a performance seems to be very limited, yet, when duly formulated, it attains not undesirable proportions, while it steadily increases with attempts at orderly distribution, and is constantly affording the means of further improvement.

The first group for consideration, as being the one easiest understood, includes those diseases which owe their origin to the presence of a vegetable parasite in the skin or its appendages. These are not influenced materially by any predisposing causes connected with the health of the individual; and, though this opinion did not always obtain, it is no longer insisted that favus, for instance, is directly associated with the scrofulous diathesis, and that only delicate children are subject to attacks of ringworm. Innumerable instances of the latter complaint attacking a succession of healthy children in a school, or of calves on a farmstead, conclusively disprove the fallacy contained in the argument of predisposition; and any necessity for impaired vitalisation as favouring their development is negated by observation of the fact that, while some forms of cryptogamic life do undoubtedly succeed only on weakly organisms, yet other forms again infest the most healthy individuals.

Inasmuch, then, as fungi which produce favus, chloasma, ringworm, demand no special conditions on the part of the skin they select for the seat of their development, and are productive of purely local diseases, so they are curable by local remedies, obeying as they all do the same general laws. They do not, however, all produce the same external appearances the utmost unlikeness, for instance, existing between the dry, scaly patch of common ringworm and the boggy abscess associated with chierium; and in explanation of such variations it

(a) Abstract of a Lecture delivered on Wednesday, Feb. 6th, at the London Hospital.

is necessary to invoke that assemblage of conditions to which the name temperament has been applied, leaving aside, as not complicating the result, any question of state of health *per se*.

Under Group I. are thus included—

- a. Favus ;
- b. Ringworm ;
- c. Ohloasma.

The microscope suffices to reveal the real nature of these diseases, the presence of which is directly traceable to growth of a vegetable mould. Their varieties will be influenced by the temperament of the individual, by the age of the affected tissues, and the part invaded. Skin, hair, and nails will present each different appearances under invasion by the same disease, and, in addition to the special body region, climate and weather, also, will influence the character of the growth.

There are two maladies concerning which an absolute dictum as to their position under Group I. must depend on further investigation—viz., alopecia areata, and molluscum contagiosum. Mr. Hutchinson inclines on clinical grounds to give them position as vegetable parasitic diseases, but defers to fix their relation pending further evidence of their fungous origin.

[A number of illustrations were here exhibited to show the extent to which the human body may sometimes be covered with the crusts formed in these diseases, without material impairment of general health, and commenting on these the lecturer pointed out that pityriasis versicolor and ringworm were mutually interchangeable diseases between adults and children, the former communicated by adults to children appearing in the garb of ringworm, and *vice versa*; and Mr. Hutchinson believes that chloasma in adults, resulting from transplantation of ringworm from children, is dependent on precisely the same form of vegetable parasite of the latter.]

In the second group to be considered, the acting cause of disease is an animal parasite, and its principal representatives are scabies and pediculosis; but it includes as well a large number of variable eruptions produced in presence of occasional parasites.

Under scabies is to be classified every form of eruption due to the presence of the scabies parasite, or itch insect. Its character will be influenced by age of patient, irritability of skin, and its liability to cell effusion, the part affected, and duration of the disease. It may be vesicular, pustular, or papular, or marked only by a red lichenoid rash; but in all conditions, the cause being the same, the terminology must likewise be the same. Similarly, however varied the appearances of the eruption produced by pediculi may be, all must be included under the name pediculosis, the features of which are likewise dependent on such characters as have already been said to influence scabies. Both diseases, moreover, may produce long-standing disturbances in the sensory endowments of the skin, which may very slowly revert to a normal condition of quiet. This condition has been distinguished by the name prurigo, as though it were a special entity, whereas it is a state induced by veritable presence of one or other forms of parasite at some antecedent period.

Besides the diseases already named, Group II. includes all eruptions and inflammatory states of the skin due to bites of insects, such as fleas, gnats, mosquitos, &c. Many eruptions occurring in individuals with specially sensitive skins are doubtless due to such causes, and most instances of prurigo urticaria, pruriginous lichen, urticaria pigmentosa, u. pustans, and many other high-sounding affections are nothing more, Mr. Hutchinson thinks, than results of flea-bites on skin of peculiar organisation, a view he has verified by careful and continued observation. Thus, one member of a family of children will alone be subject to an irritative and persistent form of eruption, and will suffer exacerbations every time it approaches a cat or a dog, or rides in a 'bus, and the scratching necessitated by the flea-bites will perpetuate and aggravate the resulting prurigo. Mr. Hutchinson

recalled one case in which a child was covered with a most alarming bullous form of purpura, the consequence of a visit to the Zoological Gardens; and he has known adults also to be the victims of eruptions caused entirely by fleas, which eruptions recur at every visitation to a fresh hotel or other place, the explanation given by the patient being that, in spite of every care, change always subjects him to an attack of nettle-rash.

Too great allowance cannot be made for personal idiosyncrasy in such matters, for the bite of a wasp may in some constitutions set up most dangerous symptoms, or that of a gadfly, an irritable tubercle which may last for months. There is reason to suppose, also, that eruptions occurring abroad, and receiving local names—viz., Natal boil, are really caused by insect bites.

Group III. includes eczema due to local causes, and is very difficult of definition. It is necessary in considering this form of eruption to regard constitutional characters as well as the local cause, so that it is practically impossible to make two sharply-limited classes according as the local or constitutional causes are the prime influencing factors. In all cases of eczema some inherited peculiarity of skin must be admitted, for, while some persons contract it on the slightest provocation, others never are affected by it.

A group, however, may be provided to include all those forms of eczema due to such exciting causes, in predisposed individuals, as are encountered by bakers, millers, dyers, paper-stainers, potboys, &c., and in most cases this form is, if slowly, curable when the local cause is removed. The discharges are irritant, and tend to maintain the disease, and may lead to spreading of the eruption from a local origin over all the body.

All forms of eczematous eruption, of whatever variety, must be included in this group, which possibly, also, should embrace those forms of the eruption found in gouty subjects, and due, it may be, to a peculiar property of the perspiration secreted locally. Mr. Hutchinson, however, cautioned his audience against assuming that he desired to include all forms under the heading given, but that very many varieties might be so classified.

The preceding groups include nearly all diseases of the skin arising locally. The fourth group is of a very different character, and includes—

Group IV.—the Exanthemata—which are, all forms of inflammation of the skin which may result from the breeding in the blood of specific and particulate forms of virus introduced from without by contagion or infection. The class comprises measles, varicella, variola, rötthela, typhus and typhoid fevers, syphilis, &c.; all observe certain stages in their course, and contagion precedes the eruption in all for a certain period, such eruption being, it may be, due to presence in the skin itself of the particulate virus. Each disease has its characteristic eruption, except syphilis, of which the rash may present imitations of every other form of skin disease.

Exanthematous eruptions are transitory, and though varying in degree and severity in different individuals, observe about the same duration, exceptions occurring, especially in varicella and syphilis, in which the eruption may be protracted, and recurrent. In all, however, sequelæ are commonly observed, the tissues being left by the fever they indicate in a state of peculiar liability to chronic inflammation, passing even into gangrene or phagedæna, e.g., cancrum oris and noma after scarlet fever; and the phagedænic changes after syphilis.

Group V.—Syphilitic eruptions.

Groups VI. and VII.—skin diseases due to acute and chronic forms of poisoning—include rashes induced by copaiba, iodine, quinine, &c., urticaria ab ingestis, &c. Though many of these are well-known and easily recognised, probably the origin of many diseases properly to be included in this group is never suspected; and even the iodide rash has only lately been fully appreciated. Obscure rashes should therefore always excite suspicion of drugs or diet, before being abandoned as inexplicable. Idiosyncrasy is the only explanation to be found for these eruptions, which

may take the most unlike forms, though due to the same cause, in different persons—arsenic, followed by eczema in some; in others, herpes zoster; and in yet others, a general psoriasis-like condition of skin. This group of rashes is transitory, but if permitted to continue too long, body changes, resulting in death may supervene.

Group VIII. includes chronic skin diseases of dietetic origin, such as leprosy, pelagra, and gouty eczema.

Group IX.—This group is made to include a large family, hitherto regarded, as a rule, as quite distinct forms. They are, in respect to cause; for the most part, inexplicable; and originating, as they appear to do, in healthy subjects, they possess a self-dependence and completeness characteristic of no other forms yet discussed. Concerning them the most hopeful dermatologist can hardly anticipate any accession of knowledge, and he must bound it by his present information of psoriasis, pemphigus lichen, ruber, leucoderms, and some others; these constituting the series in question. They begin in persons apparently in good health; they always are symmetrically disposed on the two halves of the body. They steadily increase, unless arrested in their course by appropriate treatment, which, as far as we know, is summed up in the administration of one drug—arsenic. Leucoderms may have to be excepted in this last respect, but Mr. Hutchinson is doubtful if this will be found to be so. As a rule, those diseases affect but one member of the same family; they are neither epidemic nor endemic; and position on the world's surface does not affect their prevalence. Young children are liable to them, but mere infants escape. Though arsenic cures, relapses occur; but under each disease such relapse is less severe than the original attack. Weather and season seem to exert a small influence on them.

In respect to the causation of this group, Mr. Hutchinson inclines to regard them as dependent on inherited peculiarities of structure, the sufferers from them being in a sense predestined to them from birth. In absence of a better name for the group, he entitles it the Psoriasis family.

PANARITIUM.

By THEODOR BILLROTH,

Professor of Surgery in the University of Vienna.

PANARITIUM is the unfortunate designation of an acute inflammation of the finger that may attack as well the first as the second or third phalanx, and that has its seat in the subcutaneous cellular tissue, whence the name *panaritium subcutaneum*, or in the sheath of the tendons (*panaritium tendinum*), or, lastly, in the bone (*panaritium osale*). The disease may arise in consequence of crushing, or wounds, or most frequently from infection; it usually begins with pain, from the degree of severity of which a conclusion may be drawn as to the seat of the inflammation, for in those inflammations that have their origin in the bone the pains are so intense that the sufferers, as a rule, are disturbed in their rest. The swelling in the case of *panaritium osale* is so slight that it bears no proportion to the agony endured. Such intense pain is produced by the retention of the pus beneath the periosteum. When it raises this up and escapes into the cellular tissue, the pain gradually diminishes. From the commencement of the affection until spontaneous rupture externally takes place, usually from twelve to fourteen days elapse; early incision is therefore a great relief to the patient. Incisions can be made even when the pain is most intense, the patient being narcotised, but the incision must, of course, reach down to the bone. The osteitis of the third phalanx generally ends in either total or partial necrosis of the bone. Three or four weeks elapse before the bone is separated from its surroundings—from the tendons, the articular ligaments, or, in the case of partial necrosis, from the still living bone. During this period new bone is already developed by the raised up periosteum, and even if the sequestrum

capsule is not completely tubular, in the course of time the development of the new bone may still be considerable. If an incision has been made, examination with the probe must be resorted to from time to time—about once a week—to ascertain how much of the surface of the bone is free, and if found to be fairly freed from its surroundings, it should be seized with a strong pair of forceps and quickly removed. The wound will now close, but at the same time the formation of new bone will be limited, and in consequence of contraction, to a certain extent only a rudimentary phalanx may be developed.

The finger will, of course, be always somewhat deformed, it generally becomes slightly clubbed. The incision is usually made by the side of a tendon; the tendon may already be necrosed, but it is not always so, and consequently it would not be proper to aid the occurrence of necrosis by incision. Spontaneous bursting most frequently takes place around the tip of the finger; there are cases, however, in which it takes place under the nail, or at the root of the nail. In such cases the pain is always intense as the nail is only raised up gradually, and the process of elevation is extremely painful. In cases in which the matrix is affected in the process of perforation, the nail becomes necrosed. As far as the nail looks red, it has life in it, just like hair that remains in the cutis; when matter is collected under the nail it no longer looks red and translucent, but becomes dull, milky coloured, and, later on, it becomes greyish black, a sign that the nail is already dead. Death of the matrix however, is not always associated with death of the nail; this may occur, but the death of the nail-bed is not a necessary result of the process, the nail-bed may remain, and the nail may be formed anew. One thing remains, the inflamed nail-bed never retains so smooth a form as before; it becomes uneven, knotty, and in consequence the nail is never developed with such beautiful smoothness, it remains uneven, and of a dull milky colour. In the course of years this condition may improve a little, but it never becomes good. Various attempts have been made to restrict this uneven growth of the nail, by even compression, or by scraping, but the results are only transient, as the cause of the irregular growth is not removed, the matrix still remains uneven and lumpy. When the pus is originally formed in the subcutaneous cellular tissue, an opening soon appears in the skin, where, first, a vesicle forms, from the cuticle becoming raised up from the rete malpighii. The panaritium subcutaneum has already found its way through by the fifth day, and by the twelfth, the wound is generally healed. There are also cases of panaritium in which no pus is formed, but in which complete spontaneous gangrene of the tissues takes place. How is this gangrene to be explained? In inflammation, gangrene may arise through two causes:—1. The inflammatory process may from the first be so intense that the structure immediately dies; and 2. Clotting of the blood may take place and gangrene, in consequence of the arrest of the circulation. This last possibility we cannot accept in the case of panaritium, for how could such a disturbance of circulation as leads to gangrene take place so suddenly. I have already mentioned to you that the circulation in the fingers is so active that a finger may be completely cut off, except a thin bridge of skin, and the separated part may grow on again, the circulation being carried on through the bridge of skin only.

I think gangrene would take place here from the first cause. The acute inflammation is a chemical process in the tissues which is associated with dilatation of the vessels with consequent exudation of serum, with increase of number of cells in the connective and fatty tissues, and with extravasation of white blood corpuscles, which come to light as pus. The most essential part of the affair, however, is the chemical process which changes in a manner not yet understood the inter-cellular substance and the vascular tissues. There are naturally different degrees, and these degrees are manifested in such a way that the inflammatory change, and the dis-

turbance of nutrition are small in one case whilst in another they are extreme—indeed, the peculiar disturbance of nutrition may be so intense that the vitality of the tissues ceases. This cessation of vitality is principally of importance as regards the vascular tissues, for when once the walls of a vessel are dead—as held by Brücke—clotting of the blood readily takes place. At a temperature of 1 C. (33.9 F.) no freezing takes place, and the blood as far as it alone is concerned, may still circulate, but at this temperature the tissues of the vessels die, and clotting then takes place in consequence of their death. The like is the case in various other processes—the first in order is the death of the tissues, and the stoppage of the circulation is secondary. When gangrene takes place through the action of liquid caustics alkalis, we must look upon this in the same way as being the result of the destruction of the tissues. The conditions are similar in the case of certain animal poisons, particularly the poison of serpents, for we cannot suppose that such a disturbance of circulation is set up that gangrene follows by the mechanical injury from the teeth; it is probable that the poison itself acts chemically in such a way that it kills the tissue, and that, as a consequence of the death of these, stagnation of the blood supervenes.

ON GANGRENOUS ENTERITIS AND ENTERECTOMY. (a)

By CHARLES ATKIN, L.R.C.P.Lond., M.R.C.S.,
House-Surgeon, Sheffield Infirmary; late House-Surgeon, Eye and
Ear Infirmary, Liverpool.

THE case I propose bringing under notice is interesting to all of us because of its rarity—to physicians especially, because with our present limited means of diagnosis it must have been nearly impossible to determine its character before operation; to pathologists, because no naked eye lesion to account for the gangrene could be detected; to surgeons, because when taken early similar cases, though not from the same cause, can and have been cured by operation; and, lastly, to house-surgeons, because if these cases are to be operated upon, ought one not to be prepared with the necessary apparatus, if any, indeed, be necessary?

W. H. W., æt. 30, a painter, was seized four weeks before admission with pain in the left lumbar and iliac regions, and continuous vomiting. A medical man was called in, who told him he was suffering from lead colic, as the man had had lead symptoms previously. Purgatives were administered, but no motion or flatus ever passed from him. He continued all these four weeks vomiting nearly continuously. When admitted into the infirmary he was emaciated to the last degree, pallid, weak, compressible pulse, cold extremities, faecal odour in the breath; temperature, 101.2. There was no hernia, nor had he ever had one. The abdomen was resonant, except over the lower part. There was no stricture to be felt per anum; no hardness along the rectum and colon. The ileo cæcal region was most distended. An enema could be distinctly heard with the stethoscope ascending and traversing the colon. O'Byrne's tube enters the sigmoid flexure, and is then stopped.

A consultation was held, and Mr. Favell decided to give the man the chance, however small, of having the obstruction relieved by operation, though the man was evidently nearly moribund. Ether being given, abdominal section was performed, and a piece of the small intestine immediately presented itself in a gangrenous condition; it was black, red, softened and soddened, and though it was manipulated with the greatest care, it was

evident that there was some oozing of some liquid faecal matter from it. The patient being nearly pulseless, nothing more was to be done than to carefully stitch the peritoneal edges of a small ragged rent which was found in the most soddened part of the gut. With the help of repeated hypodermic injections of ether, the patient was removed safely to bed, but only to live a couple of hours.

The autopsy was made next morning. On the abdominal cavity being laid open, the parts were carefully examined *in situ*. No internal hernia band or twist was to be found. The whole alimentary canal was then removed, carefully washed, and examined inch by inch. No hard faeces, diverticula, or stricture were visible. The heart was healthy, but his arteries were bad, and the kidney showed commencing granular changes.

Cases of "localised death of a loop of bowel" arising *de novo* are certainly uncommon, but still are well recognised as pathological rarities. As far as I know, the symptoms of enteritis are always equivocal, combining the acute pain of peritonitis with the tormina of colic. In this case there was no history of any hæmorrhage from the bowel. What, then, was the cause of the enteritis? There was nothing locally apparently to cause any inflammation, such as impacted faeces or a foreign body. The lesion did not appear to have been due to an ulcer spreading, and there was no evidence of slight invagination; there was no tumour or enlarged gland preventing the return of the venous blood from the bowel, and, as the heart was normal, embolus was out of the question. There was no history of any blow on the abdomen. One is therefore forced to assign some such reason as is often given for acute perforation of the stomach—some loss of vitality due to either deficient vascular or nervous supply. Perhaps the intrinsic ganglia of the bowel were in a state of degeneration; but more likely I should imagine that the real cause was, that one of the branches of the mesenteric artery was in a degenerated condition, and became thrombosed, thus cutting off the blood supply to a small loop of bowel. As to the question of diagnosis, I should like to hear any opinion as to whether intestinal obstruction often simulates lead colic with vomiting. Gabbatt, in a September number of the *Lancet*, 1882, records a case of fatal enteritis in a man, æt. 43. He was ill only forty-eight hours, dying of acute dilatation of the stomach. On post-mortem nothing was found to account for the three inches of inflamed bowel but a large clot in the mesentery.

In Mr. Favell's case the duration was very remarkable, for the man had been vomiting continuously for four weeks when he applied at the infirmary.

As to treatment, would early operation have saved him? Would it have been justifiable to have examined the abdominal cavity at the end of the first week, supposing he had come to the infirmary then, and supposing inflamed bowel had been found, would it have been proper treatment to remove it?

At the meeting of the British Medical Association at Liverpool the question of early operation in intestinal obstruction was freely discussed, and there remains no doubt but that the chief operative talent in England is in favour of it, though the seat of the operation is still undecided, depending as it does often on the humour of the operator and on the acuteness of the case. Median section was advocated for acute cases, and enterectomy or opening the right loin and seizing whatever bowel first presented itself for chronic cases. Two speakers spoke against early operation (Messrs. Rushton Parker, and Pemberton), and trusted to opium, ice, filtered broths, and *no milk*, but they were only content to wait as long as the cases did not go steadily to the bad.

Supposing abdominal section be performed in the median line, and that several inches of bowel are found to be gangrenous, what is to be done? Up to quite

(a) Read at the meeting of the Medical and Chirurgical Society, Sheffield, Jan. 24th, 1894.

lately the bowel was left at the mouth of the wound in the hope that an artificial anus would form, and that adhesions would prevent any faecal exudation.

But during the last two or three years several operators have improved on this "laissez aller" treatment, and successful cases have been reported of enterectomy and enterorraphy for multiple strictures, simple and malignant strictures, intussusception, gangrenous bowel after strangulation, and for the cure of artificial anus and faecal fistula. I know of no case in which it has been done for idiopathic gangrenous enteritis. Kœberle, in an article in the *Gazette Hebdomadaire* thus sums up the operations that are available on finding a portion of bowel gangrenous. You can either do (1) resection, immediate union of the divided ends and closure of the wound; (2) establish an artificial anus, and do a "suturing" enterectomy subsequently; and (3) make an incomplete suture of the intestine, associated with an artificial anus.

If I am not wearying you, I should like to give you a short résumé of the published cases that I have read of, some of which must be considered triumphs of surgical art and skill.

Czerny, in the *Berl. Klin. Woch.*, 45, 1880, published three cases, two of which recovered. The first case was the removal of a gangrenous coil from strangulated hernia, which got quite well; the second was a similar case, but the patient, already pulseless, died during the operation; the third one was in a woman, æt. 47, from whom he removed a tumour of the transverse colon; she was living half a year after the operation. His method consisted of a double row of carbolised silk sutures, and was as follows:—The intestine being compressed above and below, the tumour or gangrenous part was removed and a wedge of mesentery; the ends were then brought together and united by a row of sutures, taking up only the serous and muscular coats, 1-12th of an inch apart. A second row of sutures, 1.5th of an inch apart, were applied over and partly including the first. Antiseptic dressings were used.

Schede, in *Deutsche Medicinische Wochenschrift*, No. 19, 1879, gives details of three cases of *Enterorraphy*, one being for artificial anus, the other two for faecal fistula. Two of the cases were cured, one dying of pulmonary embolism:—

a. A woman, æt. 43, had had a strangulated femoral hernia, which, being gangrenous, ended in the formation of an artificial anus. To cure, this an incision three inches vertically was made, the upper end of the bowel dissected out and temporarily tied with catgut. The lower was treated in the same manner; then a wedge of mesentery was removed, and the ends joined together. The catgut ligatures were now removed. Fearing that there might be some leakage, the sutured bowel was not returned into the abdomen, but retained without the middle of the wound, and prevented from slipping in by a large bent needle passed through the mesentery. The exposed gut was covered by Lister's dressing. The dressing was changed on the second, sixth, and tenth days. The needle was removed on the tenth day, and the exposed coil of intestine, now covered with granulations, was allowed to fall back into the abdominal cavity. The patient was cured at the end of the fifth week.

b. A woman, æt. 62, for a large irreducible umbilical hernia of ten years' standing, continually discharging faecal matter through a fistulous ulcer. He removed four inches of the intestinal canal, and treated as in case a. The patient died of pulmonary embolism on the fourth day.

c. A woman, æt. 58, for fistulous opening below and to the right side of the navel, probably communicating with the jejunum. Incision was made, and the bowel ends joined, but it was found impossible to draw the sutured bowel out of the wound, as in the former cases, so the wound was closed. The case got well, there being normal defæcation on the fourth day.

Schede likes the temporary deligation of the bowel ends, but is not inclined to think that the retaining the sutured bowel outside the abdominal cavity is at all necessary.

Sutton, in the *American Medical News*, reported a case where, whilst removing an ovarian cyst with many firm adhesions, he tore the bowel, which was adherent to the fundus of the uterus. He united it by Czerny's method, after removing four inches of it, and the patient made a good recovery.

Mensel, of Gotha, in the *Deutsche Med. Woch.*, Feb. 14, 1883, records two cases of faecal fistula, by opening up the abdomen and suturing the intestine ends together.

I cannot close this list without mentioning Kœberle's historical case, published in the *Gazette Hebdomadaire*. A woman, æt. 22, suffering from intestinal obstruction, had abdominal section performed, and multiple strictures were found, extending over two yards of bowel. This length was removed, and the corresponding portion of mesentery, which latter was secured by twelve ligatures and cut away. The cut ends of the bowel were then placed side by side, one above the other, but not united, so that both ends were open externally. The wound was then partially closed above and below them. Three days later he proceeded to get away the "spur" formed by the two bowel walls, which were in contact with each other. This he did by inserting caoutchouc tubes and approximating them by special forceps; in twelve days the two layers of intestinal wall had aloughed, thus converting the double intestinal orifice into a single opening, communicating with both superior and inferior tracts of intestine. The fistula healed six weeks after the operation.

Mr. Treves (Dec. 16, 1882) read a paper before the Medico-Chirurgical Society of London, where, after showing that resection followed by reunion of the divided bowel was better than making an artificial anus, went on to describe a special apparatus he had had made for ensuring co-aptation whilst the sutures were being inserted. It consisted of a couple of clamps capable of being joined into a frame, and also a sausage-shaped bag of indiarubber, capable of inflation to be inserted into the collapsed ends of the intestine during the suturing.

Mr. Stanmore Bishop, of Manchester, showed a special clamp he had had made at the meeting in Liverpool. It consisted of two spring clamps held together, so as to form one piece. He says with this instrument it is possible to return the sutured bowel without any fear of having left a point unguarded.

One of the most recent articles on enterorraphy is one by Prati, in the *Annali Universi* for June. This paper, consisting as it does of twenty-seven pages, contains nothing original, excepting the author's method of suturing, which is as follows:—He first stitches half the circumference of the bowel by Lambert's method, and then stitches it again from the inside, taking up the mucous and sub-mucous membranes. The other half of the bowel he does in the reverse method—first a set of mucous membrane sutures, and then a set of peritoneal ones. He says that the projecting spur is very small, and no impediment to the passage of the intestinal contents.

Enterorraphy has been severely criticised by Byrd, who says that flatus must accumulate and tear the sutures open, and he recommends excising the bowel for enterectomy, and making an artificial anus.

It may be said that stricture of the bowel would follow on resection, but it is not so, because union takes place by the first intention.

Again, it has been said that by only stitching the peritoneal coats together, as taught by Lambert, an annular projection of mucous membrane would result, thus tending to occlude the lumen of the bowel, but really this *éperon* never forms, and indeed may easily be

prevented by snipping the mucous coat all round a little shorter than the outer coats.

Another argument has been used against the operation—that it would be impossible to join the end of a dilated bowel above to that of a contracted one below; they would be so dissimilar in shape that they could not possibly be accurately brought together, but this is overcome by the same method Billroth did with the stomach and duodenum when he had excised the pylorus—viz., by cutting the duodenum obliquely to its long diameter.

I cannot close without mentioning the successful case operated on by Mr. Banks, of Liverpool, who removed eight inches of bowel and a wedge of omentum.

I am aware that the list of cases I have read to you is incomplete, but without a good reference library at hand it is unavoidable. Foreign papers are not easy to get in the provinces. However, the most important ones, I believe, I have set before you, and I hope the day is not far distant when some triumph of abdominal surgery of the nature I have been reading this evening will be performed and published by some member of this Society.

NOTE ON THE TREATMENT OF FLAT-FOOT.

By W. J. WALSHAM, F.R.C.S. Eng.,

Assistant-Surgeon to, and Surgeon in charge of, the Orthopædic Department St. Bartholomew's Hospital.

THE boot represented in the accompanying wood-cut is one which I have found of much service in the treatment of certain forms of flat-foot in the Orthopædic Department of St. Bartholomew's Hospital. It differs from the boot with outside leg-iron in ordinary use,

inasmuch as in place of the T-strap I have substituted a broad band of solid rubber, so that continuous elastic tension is exercised on the sunken arch. The rubber band is firmly secured to the "uppers" inside the boot along the outer border of the sole, in such a position that, as it crosses under the sole of the foot its centre corresponds to the middle of the calcaneo-scapoid ligament. It is then carried up on the inner side of the foot to just above the top of the boot, and thence, through the medium of a leather strap and buckle, secured to the calf-piece. A soft valgus pad is slid over the rubber strap, and so adjusted as to correspond, when in position, to the situation of the yielding arch. In place, therefore, of a passive and algal pad to support the arch, active traction through the medium of the pad is exercised on the depressed bones by the rubber strap. For convenience of treatment, ordinary forms of flat-foot may be divided roughly into three degrees. In the first in which little yielding of the ligaments has taken place, tip-toe exercise combined with circumduction of the ankle, will generally be found sufficient to produce a cure; if the patient will wear a well-formed laced-up boot with a soft felt valgus

pad, and is able to reduce somewhat the hours of standing. In the third form, in which the arch is completely sunken, and there is much rigidity of the foot, I know of no treatment which answers so well as that practised by Mr. Willett, and described by him in the eighteenth volume of St. Bartholomew's Hospital Reports, viz., thorough wrenching of the foot under an anæsthetic, and then placing it in a plaster-of-Paris case in a position of extreme inversion, with the bones forming the arch forced well into place. In the second form, in which the deformity is well marked, but is unaccompanied by rigidity, I have obtained the best results by the boot above described. I have tried it now in upwards of a dozen cases, and in every instance the patients have expressed themselves as experiencing great comfort from its use, and have obtained permanent benefit. The boot was first made for me by Messrs. Arnold and Sons, of West Smithfield.

Clinical Records.

CASES IN PRIVATE PRACTICE.

Case of Unilateral Progressive Atrophy of the Face.

Under the care of Dr. H. FRENCH BANHAM, Physician to the Sheffield General Infirmary.

THE patient is a girl, æt. 15, and (attention not being given to the right side of the face), good-looking, and with the appearance of robust health. She is, generally speaking, muscular and well-formed. Four years ago she had a bad gum-boil connected with a carious bicuspid of the right side of the lower jaw. In the course of a day or two, the face meanwhile being considerably swollen, the gumboil burst and discharged rather freely. The tooth was subsequently extracted. She had always enjoyed very good health.

About six months after the gumboil there was some hyperæsthesia of the right side of the face, and also of the right ear, and this condition has continued until nearly the present time. Two years ago her parents noticed some wasting of the face, which it was thought had resulted in some way from the old gumboil, and about the same time some discoloration of the skin was observed on the right side of the neck.

At the present time there is marked wasting of the right side of the face, and a considerable depression is observable immediately below and in front of the ear, and a deep pit is also seen between the ascending ramus of the lower jaw and the sterno-mastoid muscle. On the right side of the neck and over the sterno-mastoid muscle, the skin, which has a dirty, discoloured appearance, is dry, and has apparently lost its subcutaneous fat. It can be readily raised from the subcutaneous tissue, and imparts to the fingers the feeling very much of thin flannel. She complains of no pain, and sensation appears to be normal. The movements of mastication are in no way interfered with. The blood-vessels, as far as can be ascertained, are normal. The hair on the right side of the head has a natural, healthy appearance.

The records of progressive unilateral atrophy of the face are comparatively rare, and the present case, although resembling some that have been published, has also points of interest specially its own.

The female sex seems to suffer more frequently from this condition than the male; but this case is somewhat peculiar in that the right is the affected side. The hair also has undergone no change, and the atrophic and colour changes in the skin are almost confined to the neck. On first seeing this case I supposed that the masseter muscle had undergone atrophy. I feel, however, now satisfied, from her masticatory power and her ability to divide hard substances, crack nuts, &c., being normal and equal on the two sides, that the wasting is only of connective tissue. There is no obvious alteration in the functions of the parotid gland, but I am convinced that its connective tissue is greatly wasted, and that the gland itself is considerably diminished in bulk. I do not think that any wasting of the bones has taken place. The connection between the carious tooth, the gumboil, and the subsequent atrophic changes may be purely accidental, but the possibility of their being connected as the result of an ascending neuritis should, I think, be borne in mind.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

ANGINA PECTORIS.—At the Académie de Médecine a member brought under the notice of his colleagues the results of an autopsy made on a man who succumbed two days after his entering the Hotel Dieu to an attack of angina pectoris. For a year and a half previously he used to complain of severe pain in the præcordial region, with constriction of the base of the thorax, and irradiation of the pain toward the left shoulder and down the inside of the arm. The attacks at first took place every month, but afterwards became more frequent, recurring three or four times a week. The access was generally brought on by an emotion, quick walking, and especially by a copious repast; it lasted from a quarter to half an hour. Auscultation revealed a bruit at the first sound. At the autopsy a very notable dilatation of the aorta was found at its origin, and was diagnosed during life, with insufficiency of the valves of the same name, although the sigmoid valves were perfectly healthy. But what above all struck the attention was the exceedingly narrow orifice of the coronary arteries. The member concluded in giving it as his opinion that the malady was produced by the lesion already mentioned of the coronary arteries, and cited the observations of Potain, Séi, Huchard, &c., in support of this idea.

TREATMENT OF GENU VALGUM.—At the Société de Chirurgie on a discussion as to the relative value of osteoclasy and osteotomy in the treatment of genu valgum, M. Hillary reminded his colleagues that he was the first in France to practice the former operation. Since that time (1875) he had performed osteoclasy above thirty times, and he would always prefer it to osteotomy for he obtained very good results, and in his opinion a simple fracture is a great deal better than one complicated with a wound. M. Deleus said that since 1875 he practised ten times the operation of forced extension of the extremities for genu valgum. In six cases he tried with comparative success osteoclasy, but considerable effusion took place in the articulation which gave some trouble; in the remaining four cases osteotomy was tried and the result was perfect, so that he could not help expressing himself in favour of the cutting operation. M. Desprès was incredulous as to the results stated, but M. Verneuil said he had three cases of genu valgum for which he had recourse to osteoclasy with great success; the femur was fractured a little distance from the articulation so that no injury resulted to the joint. M. Gillette presented a young man who had been subjected some months before to the operation in question and was now perfectly well, the limb was quite straight and free of claudication. The femur was fractured above the epiphysis and the limb was placed and left for two months in a starch bandage.

EXTRACTION OF TEETH WITHOUT PAIN.—At the Société de Biologie M. Paul Bert introduced to his colleagues a method recently discovered by a Geneva dentist for extraction of teeth without pain. The method is very simple and can be used by the most ignorant; it consists of a piece of india rubber through which a hole has been made to receive the crown of the tooth, pressed down tightly in the gums and left *in situ*. By the heat of the mouth the elastic contracts, and by that operation the tooth is loosened in its alveoli, and finally is lifted completely out of its bed to the relief of the patient. It takes four or five days to effect its purpose. Any improvised piece of caoutchouc would do.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 8TH, 1884.

The President, Sir ANDREW CLARK, Bart., M.D., LL.D., in the chair.

Mr. PEARCE GOULD related the history of a case of SPREADING AND OBLITERATIVE ARTERITIS,

the patient being shown. It occurred in a lad, æt. 19, in whose family and personal history there was nothing to throw light upon the cause of the disease. The illness began in May, 1883, when the man noticed the fingers of his right hand becoming dark in colour; when warm the hand was of a deep red colour; when cold it became first blue, and then dead white, and there was then a sickening pain in it. After three weeks he rested from his work (in a brick-yard) for three weeks; but, again, after working for a month, the hand became worse, and he had to rest for a month. He then thought himself well, but, on resuming work, "the pain went" into his forearm and elbow, and since then he had been unable to work. He was admitted into the London Temperance Hospital on Oct. 31st. The right forearm and hand were colder than the left—somewhat wasted; while the hand was warm he could wash with it, and it quickly became cold and painful: the pain was always worse at night. The brachial artery in its whole course was harder than the left, and less affected by the pulse, which ceased in it just above the elbow-joint. The radial artery was felt as a prominent, hard, pulseless cord; there was no pulse in the ulnar artery. The other arteries of the body appeared normal. There was a small patch of dry gangrene on the tips of each of the 1st, 3rd, and 4th digits. Heart, normal; accentuation of second sound over aortic cartilage. Urine, normal; temperature, normal. For about a fortnight there was no notable change, but then the pain increased, first at night, and then by day, until it became so severe that the patient writhed in agony, which was only partially subdued by repeated hypodermic injections of morphia and draughts of chloral and bromide of potassium. Concurrently with this the pulse in the brachial artery faded away, until the vessel formed a hard, pulseless cord as high as one inch below the teres major tendon. On November 23rd the right subclavian artery was noticed to be very prominent above the clavicle, and the heart's action was excited. In December the pain lessened, and by Dec. 17th was but slight, while the prominence of the subclavian artery was diminished. Now he is quite free from pain, and expresses himself as quite well. Nearly the whole of the last joints of the thumb and of the right ring finger have mummified, and are nearly detached. The limb is considerably wasted; the radial artery has so shrunk as to be scarcely perceptible, but is quite pulseless; the brachial artery is still felt as a firm pulseless cord to within an inch of its origin. Mr. Gould stated that at no time had there been any œdema of the part, or any loss of sensation, the only paræsthesia being intense pain, particularly complained of in the parts which afterwards became gangrenous. The temperature was normal on the patient's admission to hospital, but on Nov. 26th was found to be pyrexial, and it continued so, ranging between 99° and 101° until Dec. 18th; when it finally returned to the normal: on one occasion the temperature rose to 101·8°. Mr. Gould remarked that the history and progress of the case plainly indicated that the disease was a progressive obliteration of the arteries of the right upper limb, probably starting in the hand and spreading almost up to the axilla. There was no source of embolism discoverable, and the slow progression, the marked induration of the vessels before pulsation was lost, was sufficient to exclude simple thrombosis, especially in the arteries of the upper limb of a lad of this age. He believed that the disease was a primary inflammation of the arterial coats—arteritis obliterans—such as that described by Friedländer, and had been examined very carefully in one case by Winiwarter. Jasch and others had reported similar cases, and the disease strongly resembled that described by Heubner in the cerebral arteries in syphilis. The present case, however, was especially noteworthy as occurring at an earlier age than any before recorded, and affecting the upper rather than the lower limb. There was

no history or evidence of syphilis in his patient, and Mr. Gould was unable to fasten on the cause of the affection. It was important to notice the very small amount of gangrene that resulted from so extensive an obliteration of the main arteries of the part.

Dr. W. B. HADDEN on a case of

OBSTRUCTIVE ARTERITIS.

An unmarried woman, set 35, was admitted, under Dr. Bristowe, at St. Thomas's Hospital, on Feb. 22nd, 1882. There was nothing of importance in the family history and no reason to suspect syphilis. The patient had been accustomed to sleep with an invalid child, and her arm, which was placed around the child, used to hang outside the bedclothes. Six months before admission she had severe pain in the right arm, shooting down the hand; and two months before admission the tips of the first and second fingers were hard and cracked. On admission, she was a healthy, well-nourished woman, without any visceral disease. She complained of constant pain, but occasionally shooting, in the thumb and first and second fingers of the right hand. The fingers were pale and cold, and on the tip of each there was a flat, irregular corn. The thumb was pale, cold, and stiff, and top was hard and thick. There was no pulsation in the radial and ulnar, and the former was hard and tender. Pulsation was felt in the arteries at the bend of the elbow. Subsequently, pulsation could not be felt in the lower part of the axillary, and there was tenderness along the whole brachial. The hand and arm became very cold, and the fingers livid. Surface temperatures were taken, and it was found that the right upper extremity was much colder than the left. Later, the tenderness in the course of the arteries became more excessive, and the absence of pulsation extended higher into the axillary artery. The skin over the ends of the thumb and first three fingers became gangrenous, and was separated. Finally, pulsation returned in the brachial as far as the end of the elbow. Six months later the patient wrote to say that she was quite well, but that there was no pulse at the wrist. Prolonged pressure on the arteries seemed to be the exciting cause, just as it is sometimes in the case of a nerve. The favourable termination, as in paralysis, is worthy of note.

Dr. MAHOMED trusted that the authors would continue to observe the progress of the two patients under their care. He (Dr. Mahomed) had experienced a similar case which terminated fatally. It was that of a man under Dr. Moxon's care, who suffered from attacks of pain down one arm, accompanied by angina pectoris. Thrill and bruit were distinguished in the subclavian artery, and aneurism was suggested as a cause; but Dr. Moxon's opinion was that it was a case of arteritis. This was shown to be the case by post-mortem examination of the body. Moreover, the pulse-tracing was not that of aneurism, although at the time it was taken, 14 years ago, the information obtainable in this connection was very much less than existed at the present time. Dr. Mahomed considered that Mr. Gould's case might terminate in angina, or some grave aortic disease.

Mr. BRYANT observed that it was difficult to find explanation of origin of arteritis. Might not Mr. Gould's case have originated in thrombosis? The bony growth described might possibly be an extra rib, and by producing irritation of the artery arching over it, set up conditions favourable to thrombosis. Dr. Hadden's case lent support to the view that local pressure might induce these results.

Mr. CRIPPS congratulated Mr. Gould on the excellence of his paper, but objected to the method of arriving at a diagnosis which it described. Endarteritis was not sufficiently evidenced by it. In one case he examined he had found a prominent bony mass on both sides of the last cervical vertebra, by which forward pressure was caused on the subclavian artery. Obliteration of distant small vessels was thus favoured by deposition in them of fibrin, owing to pressure on the main trunk. The occurrence of such result at a particular age would be determined by sudden increase of growth in the bony mass, as instanced in a case under treatment at St. Bartholomew's Hospital in which aneurism was caused in a young man by exostosis. Clotting would, Mr. Cripps thought, commence in the finer vessels and spread upward to the larger ones.

Mr. HUTCHINSON briefly recorded three cases of arteritis not due to atheroma. The first was attributed to syphilitic origin. The little and ring fingers of the patient became blue, though not actually gangrenous, and were very painful. In the second, undoubted arteritis occurred in an old

gentleman upwards of eighty years old. His first complaint was that he could not endure the pressure of a hat without discomfort. Both temporal arteries were hard, red, pulseless, and tender. Absolute obliteration of these vessels ensued, and the patient quite recovered. No suspicion of syphilis was entertained in this case, but it was evidently one of senile change, assisted by pressure of the hat brim. In the third case, that of a man about sixty years old, a slight burn on the fingers was followed by gangrene of the hand, resulting, probably, from arterial obliteration, and passing gradually up from the periphery, as in Mr. Gould's patient, finally implicated the axillary trunk, and amputation at the shoulder-joint was resorted to. No bleeding took place from the vessel, which was obliterated by a clot of fibrin. The vessels were extremely tortuous, but contained no calcareous deposit. In this case it could not be precisely stated whether arteritis or periarteritis existed, but obliteration of the smaller vessels first took place, and then spread up the limb. It had not been proved that inflammation within the vessel occurred in Mr. Gould's case. Thrombosis might have succeeded to pressure on the artery above and it was extremely interesting to observe how disease did not set in at the seat of such pressure, but at a situation distant therefrom. Mr. Hutchinson expressed a cordial admiration for the excellent way in which Mr. Gould had constructed his paper.

Dr. MONEY remarked that he had recently found many evidences of arteritis in the vessels of a spinal cord taken from the body of a patient subject to lead palsy, and he suggested that lead might possibly cause such changes as were under discussion.

Mr. MORGAN said that the case he had reported to the Society three or four years ago, and which had been referred to in the paper, differed from Mr. Gould's in the uncertainty whether it really could be correctly called one of arteritis rather than of peri-arteritis. The patient was a man, in whom the disease proceeded downwards to peripheral distribution. It resembled Mr. Gould's case in no particular scarcely. The pain, preceded by gangrene, described in Mr. Gould's case might possibly have been caused by pressure of the osteoid mass on contiguous nerves.

Mr. GOULD replied that pain was experienced in his case before commencement of gangrene; though inflammation was the main element for consideration, it was possible that thrombosis might attend it. By careful examination of the bony mass in the neck he had convinced himself that it was symmetrical, and as it could not thus affect one side alone, he was unable to assign to it the rôle several speakers ascribed to it. Neither could he understand how pressure at a single point could influence the changes apparent below, especially as the affected vessel had since receded from the prominent position it formerly occupied. He still regarded the case as one of arteritis, and thanked Mr. Bryant for pointing out that this affection was not induced in subjects of aneurism, in whom compression of an artery was resorted to for purpose of cure. He had specially excluded from consideration cases which were attributable to syphilis and atheroma; and by reason of the age and condition of the arterial system in Mr. Hutchinson's patients, he concluded that they bore no resemblance to his own.

Dr. HADDEN said that no bony growth had been observed in his case; and he hoped to have further opportunities of examining it.

Dr. BURNLEY YEO on a case of

PYREXIAL SYPHILIS.

This case was admitted into King's College Hospital on October 10th, 1883, with symptoms of pyrexia—high temperature, with great diurnal fluctuations, twice reaching 105° F., and four times 104° F., and averaging in the evening for three weeks from 103° to 104°. The daily oscillations were often more than 6° F. The other symptoms were pains in the limbs and trunk, headache, thirst, sleeplessness, great debility, and rapid emaciation. Between a fortnight and three weeks after his admission symptoms appeared, chiefly on the back and legs, resembling imperfectly-developed variolous pustules without the areola. Considerable doubt as to the nature of the case was at first felt, but after he had been in the hospital three weeks he confessed to one of Dr. Yeo's clerks that he had venereal sores on the penis. Anti-syphilitic treatment was attended by a rapid fall of temperature to normal, rapid improvement of nutrition, and recovery of strength,

and rapid drying up of the pustular eruptions. He left the hospital on December 20th, having been for some time quite free from symptoms of any kind. The chief peculiarities of this case were—1. The great and continued elevation of temperature, and its great daily oscillations; 2. The early appearance of the pyrexia, within 25 to 30 days of the exposure to infection; 3. The absence of any definite relation between the temperature and the eruption, which was not fully developed till three or four weeks after the onset of fever; 4. The occurrence of profound constitutional affection without any noticeable induration about the local sores. Dr. Yeo, in conclusion, called attention to the opinions expressed by Sir William Gull, Sir James Paget, Mr. Hutchinson, and others, in the debate on syphilis at the Pathological Society, and referred to Güntz's observations on the pyrexia of syphilis. He also pointed out the important pathological analogies and practical suggestions to which a case like this gave rise.

Dr. MACLAGAN said that thanks were due to Dr. Yeo for bringing forward this case, such instances of pyrexial syphilis being very infrequent. For the reason, however, that vesicular eruptions were so unusual in syphilitic subjects, it might be that Dr. Yeo had erred in calling his case one of syphilis. In typhoid, pyrexial symptoms were sometimes alone present, without any bowel complications. He inclined to regard syphilis as an accident in Dr. Yeo's case, which was probably one of blood-poisoning or typhoid fever.

Sir ANDREW CLARK instanced a case in proof of the belief, which he fully entertained, that vesicular eruptions do occasionally occur in syphilitic patients.

Mr. HUTCHINSON did not consider there could be any doubt that Dr. Yeo's case was one of syphilitic pyrexia; such cases were not very uncommon, and sometimes pyrexia and severe illness were accompaniments of early stages of the disease. He did not think there was any absurdity in styling the eruption a syphilitic variola, and many patients found admission to small-pox hospitals by reason of presenting such a rash. A private case in point had recently occurred within his own experience. Was the syphilitic eruption exactly like variola? He did not feel quite certain that Dr. Burney Yeo had obtained the exact date at which his patient was infected; still, though the period of inoculation was a short one, it was not improbable that it might be truly stated.

Dr. DUCKWORTH said he had seen many cases of syphilitic fever, chiefly among women.

Mr. M. BAKER suggested whether the case was possibly not one of syphilis, the sores not being indurated, nor the glands much enlarged, and the eruption not having been diagnosed as syphilitic.

Dr. COUPLAND inquired whether the fever might not have had a septic origin from the neglected ulcers which had been found on the penis.

Dr. TONG SMITH narrated the history of a case admitted to the London Fever Hospital in which an eruption was thought to be erythema nodosum. The temperature of the patient fluctuated from high to normal, but at length enlarged inguinal glands being observed, together with falling away of hair, &c., suspicions of syphilis were entertained, and mercury administered, with resulting cure.

Dr. STREUNELL detailed the account of a similar case observed at the Small-pox Hospital.

Dr. BURNY YEO, in reply to Sir Andrew Clark, said that no sweating occurred in his case. The similarity between the temperature chart it presented and that of typhoid fever had been recognised, but it was not possible to entertain the theory of the case being one of typhoid. Dr. Duffin diagnosed it as febrile syphilis, and the patient himself had afforded the information that he had become infected. Septic fever had also been thought of, but excluded as an explanation of the symptoms.

THE SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, JANUARY 24TH.

The President, Dr. BANHAM, in the Chair.

ABDOMINAL TUMOUR.

Mr. E. SKINNER again brought the little boy, *æt.* about 6 years, the subject of a large abdominal tumour in the right space between the false ribs and crest of the ileum, the particulars of which have been reported in the summary of pre-

vious proceedings of the Society. There was very evident enlargement of the growth. There was considerable difficulty in coming to a conclusion as to its true nature. Encephaloid cancerous disease was most favoured, but there were some points connected with the case which made it difficult to pronounce a positive opinion.

Dr. THOMAS was decidedly in favour of its being encephaloid disease.

Dr. DYSON, whilst strongly inclined to this opinion, yet expressed it as his experience of such cases, that there was usually a much greater amount of enlargement of the superficial veins.

The PRESIDENT also regarded the case as one of probable cancer, but thought that possible hydronephrosis of the kidney must be borne in mind.

TUMOURS OF THE PONS VAROLII.

The PRESIDENT showed the brain of a man who had been under his care in the General Infirmary, Sheffield, the nature of whose disease he had correctly diagnosed during life, his opinion being confirmed by the post-mortem examination. [Notes of this case are promised for publication in a future number of the *Medical Press and Circular*, when there has been time to examine microscopically the nature of the tumours.]

SCIRRHUS OF THE LIVER IMPLICATING COMMON BILE DUCT, ETC.

Dr. THOMAS exhibited some morbid specimens from a patient who died at the Sheffield Public Hospital and Dispensary. These were, a scirrhous tumour in the left iliac fossa implicating a portion of the bowel; scirrhous of the peritoneum; scirrhous of the liver implicating the common duct. The lumbar glands, diaphragm and lower portion of the right lung, were also invaded by the same form of cancerous disease. Microscopical sections made by Dr. Sinclair White, of the Sheffield Public Hospital and Dispensary, showing the usual appearances of the disease, were exhibited.

Dr. THOMAS drew the attention of the members to the fact that palpation in this case afforded no aid in diagnosis, and also that the case showed that malignant disease extended by contiguity of structure, as it had evidently extended from the pleural surface of the diaphragm to the base of the right lung.

SCIRRHUS OF THE PYLORUS.

Mr. C. ATKIN showed for Mr. A. Jackson a specimen of scirrhous cancer of the pylorus.

MYOPIA IN SCHOOLS.

Mr. SIMON SNELL referred in the outset to the generally-accepted opinion as to the influence of school life on the causation of myopia. Passing to the subjects in hand, he mentioned the importance of any improvements that would keep the scholar's eyes at a good distance from his task. The ordinary slates in common use had for long been felt to be unsatisfactory, on account of the little contrast between their surfaces and the markings of the pencil, and which was rendered even less when the slate had become greasy. Allusion was made to the greater contrast of pen and ink marks on white paper, and to the experiments in schools at Zurich, under Professor Horner, where ink and paper were adopted in preference to slates. Cohn, of Breslau, had, however, devised white composition slates. An ordinary lead, or a specially used black pencil was employed. Other marks were easily erased. Specimens of these slates were shown, and their use recommended, and Mr. Snell stated that he had hopes that one large school in Sheffield would adopt them. Reference was briefly made also to the printing of school books, and to the very valuable and interesting articles in the *Annales d'Oculistique* some time since on the "Physiology of Reading," by Javal. This observer had made the important discovery that on reading the eye runs along the upper part of a line, and sees it more clearly than the lower half. Examples of printing illustrating this were shown, and the explanation by Javal was mentioned, as well as the hints this observer drew from this fact for the formation of type.

Mr. C. ATKIN read a paper on

GANGRENOUS ENTERITIS, WITH REMARKS ON ENTERECTOMY, which will be found on page 134.

Drs. MARTIN, DYSON, BALDWIN, THOMAS, Mr. B. WALKER, and the PRESIDENT made remarks on the subject, to which Mr. ATKIN replied. When doing so, he spoke strongly of the good effects of the subcutaneous injection of ether in 20-minim

doses in combating the tendency to death from shock after the operation of abdominal section. He has never seen abscess or other unpleasantness result from these injections.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 13, 1884.

THE PENALTY WE PAY FOR TYPHOID FEVER.

In a popular lecture, recently delivered, on "The Morals of the Drains," Dr. Crichton Browne endeavoured to enable his auditors to form some estimate of what typhoid fever really means to the country, and of the amount of death, disability, and expense for which it is annually responsible. "From the Reports of the Registrar-General," he said, "for the last year for which they are available, we find that typhoid fever caused 5,529 deaths in England, Scotland, and Wales. That is a large destruction of human life, far greater than what took place in the ranks of the allied armies at Waterloo, when the killed numbered 4,172, and what is more, it is an altogether wasteful destruction of human life. Those who fell on the plain near Brussels dragged down with them the power of Napoleon, and secured to Europe a long period of peace, but the victims of typhoid fever purchase nothing by their fate but sorrow and suffering to those who are left behind. Then Waterloo took place once for all, but the battle with typhoid fever is renewed year after year, and every circle of the sun sees upwards of 5,000 of our fellow countrymen struck down by the attacks of this ruthless invader. But to say that 5,529 persons were killed in one year in England, Scotland, and Wales by typhoid fever conveys as little idea of the

devastation wrought by that malady as the death-roll of a battle does of the horrors of a campaign. Pray bear in mind that these 5,529 victims of typhoid fever are not, as is the case with the victims of so many other diseases, feeble, worn out, and comparatively useless beings, but the flower of our population—for typhoid fever does not chiefly assail the very young, the very aged, or those who have been debilitated by sickness, poverty and trouble, and worsted in the struggle for life; but the adolescent, the vigorous, the robust, those who are entering on the conflict with high hopes and bounteous gifts, or who are at the zenith of their powers—young men and maidens, bread-winners, mothers of families, men of genius, those, in fact, who can least be spared. Unlike Pallida Mars, which Horace tells us—"æquo pulsat pede pauperum tabernas Regumque turres"—unlike Pallida Mars, typhoid fever exhibits a distinct preference for the dwellings of the affluent classes, and while it does not ignore those hovels and dens which are the favourite haunts of typhus fever, and from which such bitter cries ascend, it calls more frequently at the houses of the well-to-do, and the mansions of the rich. Like one of our colonies to which emigration is going on, it seems to say, "I want not your paupers, invalids, nor cripples, not the off-scourings of your cities and fields, the helpless and broken down, but I will take gladly your comely girls and strong limbed lads, your trained artisans, your men of muscle, of brain, and of capital!" And this being so, you can understand how serious is the drain on the best blood of the country that typhoid fever keeps up, and how the figures which I have quoted, as representing the annual mortality from it are significant of a far greater social calamity than would be indicated by a similar rate of mortality in most other diseases.

But, further than this, I must ask you to bear in mind that the mortality from typhoid fever is, in other senses, but an imperfect criterion of the havoc which it causes. We must count up the wounded as well as the killed, those who have been temporarily disabled by it, as well as those whom it has destroyed, and in attempting a computation of this kind, we must ascertain the rate of mortality amongst cases of typhoid fever. The most trustworthy statistics on this point guide to the conclusion that while the rate of mortality varies considerably at different times and in different places, and at different ages, it is generally about twenty per cent.; that is to say that of every five cases of typhoid fever one ends in death and four in recovery, and thus every fatal case represents five cases of the disease. We shall, therefore be within the mark if we say that there are in England, Scotland and Wales 27,600 cases of typhoid fever every year. Now, the average duration of a case of typhoid fever may be taken as three weeks, and we shall again be well within the mark if we add to this period another three weeks for convalescence. We have thus 27,600 persons withdrawn from productive labour for six weeks every year by typhoid fever. Now, if, on a low estimate considering the position of the classes principally affected by typhoid fever, we put the earnings of those who suffer from it at a pound a week each, and if we add to this the cost of attendance

upon them during the persistence of the fever, a period of three weeks at a pound a week, we shall find that this one disease is costing the country close on a quarter of a million of money annually, a sum which judiciously expended would before many years banish it from our island.

But we have not yet exhausted the penalties which we pay for typhoid fever. It is one of those diseases that is often followed by *sequelæ* or secondary disorders and that almost invariably leaves its mark upon the system. An eminent physician has remarked that a man cannot be said to have recovered fully from an attack of typhoid fever for five years. What he means is that long after all the symptoms of the disease have passed away there remain a certain constitutional weakness and incapacity for exertion which are not altogether removed for a series of years. And more obvious and unequivocal consequences than those comprised under general debility are constantly observed in its wake, including mental imbecility, which may last for a few months or be permanent; paralysis, deafness, blindness, exfoliation of bones, dyspepsia, and many other disorders which it would be tedious to enumerate. It may be received, however, as an established fact that a large amount of disease comes indirectly from typhoid fever, and that our hospitals and almshouses and lunatic asylums are recruited to some extent by those upon whom it has left its stamp and who but for its malignant and far-reaching influence would have been healthy and self-supporting men and women. We have no means of calculating the indirect damages caused by this great national pest, nor can we fathom the vast ocean of mental suffering for which it is responsible. Who can measure the anxieties of the watchers who stand through haggard days and dismal nights by the bedsides of those whom it has prostrated, while the issues of life and death tremble in the balance? Or who can adequately tell the tale of sorrow and privations in those homes that it leaves desolate? Could we all but realise the misery and loss and cost that typhoid fever entails on this highly-favoured land, and could we but grasp at the same time the truth that it is a preventable disease, no necessary part of the order of things, but the result of negligence and dirt, we should not rest until we had taken steps to limit its ravages, and of these steps one of the first should be to set our drains in order.

POISONOUS SNAKES AND THEIR VENOM.

In the paper read by Sir Joseph Fayrer at a recent meeting of the Medical Society of London, all that is known with regard to the effects of snake venom on living creatures, as well as the present aspect of treatment of the poisoned individual was fully and ably discussed. The importance of the subject is attested by the fact that in India, according to official statistics, the deaths by snake-bite amount to an average of 20,000 persons per annum, and by the further and very deplorable fact that, notwithstanding every means that has from time to time been tried as an antidote against the poison of these reptiles, death as surely follows the bite of a full-

grown and strong snake endowed with poison glands and fangs as it ever has done, even from the most ancient times recorded in history. In comparison with this fact all other relation to the study of *thanatophidia* are secondary in importance.

No doubt, a ready and convenient method of classifying Indian snakes is to divide them into viperiform and colubriform. The general aspect of a representative specimen of each of these is sufficiently characterised—i.e., to be at once recognised even by a non-scientific observer, and when it becomes practicable to examine the jaws of these reptiles, either during life or after death, the presence or absence of poison fangs supplies the very simple and conclusive diagnostic; there is also the easily remembered fact that all viperidæ are venomous. With regard to the colubriform, however, not only does the class comprise several kinds, the bite of any member of which is extremely venomous, as also several that are innocuous, but in general outward appearance the characters so closely resemble each other that, except perhaps a trained ophiologist, no one else coming suddenly—in the jungle or arid plain—upon a snake some six feet long and upwards, could at once determine whether it was an innocuous or venomous colubriform reptile. In order to extend knowledge on this point the Government of Madras, some years ago, sanctioned the publication of well-executed prints representing the several orders of snakes; these prints were circulated throughout the Presidency, but it is feared that the classes of natives most liable to be bitten by snakes benefit little, or not at all, thereby—namely, the Ryots, or agricultural labourers, and the poorer classes, generally, who live and sleep in fragile huts, the floor of which is level with the ground, or on low bedsteads called charpoys in the open air. It is usually said, and apparently with truth, that whereas in the fields the greater number of accidents occur from the Daboia, a member of the viperidæ, the majority of persons who are bitten during sleep are so by either the Cobra, or Bungarus (Krite). As a rule, the position of the bite is in a measure characteristic of the kind of snake inflicting the injury; the vipers scarcely raise the head when they bite, hence the majority of wounds inflicted by them are no higher up the limb than the dorsum of the foot, or the ankle; the elapidæ, on the other hand, raise the head considerably when they bite, the extent to which they are able to do so being equal to one-third of the length of the reptile. Fortunately, this habit of raising the head often affords a person a very ready means of averting the danger threatened, and destroying the animal, as the vertebrae are very readily broken when the creature is in its characteristic attitude of offence, by a smartly delivered horizontal blow with a stick or small cane. In the case of the terrible Hamadryad of Burmah, the “hill cobra” of the Madras Presidency, a reptile of full grown size, twelve feet in length, its head erect to the proportionate height already indicated, a good deal of resolution is required to stand and deliver the necessary blow. The latter snake, like its race in general, flees from man as a general rule; during the rainy season, however, that is, during their breeding season, it would appear that this rule is by no means

without its exceptions. The efficiency as a penetrating and injecting instrument of the poison fang is of three degrees of completeness increasing from the hydrophida through the elapidæ to the viperidæ in which it attains its most perfect condition for dealing death. The physical and chemical characters of the poison of different sub-divisions of venomous snakes vary, and so do also the physiological effects severally produced by them, although, in regard to each kind, the particular phenomena are similar in themselves throughout nearly the whole range of warm and cold-blooded animals, poisonous snakes alone excepted; in them, the poison, whether of themselves or individuals of the same or of altogether different genera and species, has no effect whatever. Geographical position, even in the same country, modifies the degree of virulence of snake-poison, and there is the further difference observed in phenomena caused by the same genus of venomous snake, according as to whether the reptile belongs to Asia, Africa, America, or Australia. The further peculiarity was noticed, that whereas the venom of some kinds of snakes, more especially the Crotaline, resists a temperature equal to that of boiling water, an exception to the rule occurs in member of the same order, namely, that of the *Crotalus adamanteus*, it seems to be destroyed by a temperature of 175° F. The poison of all kinds of thanatophidia appears to be destroyed when treated in the chemical laboratory with the various preparations of bromine, iodine, and permanganate of potass. In actual experiment, however, each and every such reagent has been powerless to arrest, or even modify, the power of snake poison when it has been fairly injected into the tissues of a living animal. Persons who have witnessed cases of snake bite in India are familiar with the difference between the effects of the Cobra poison and that of the Dabdia—in the former the coagulability of the blood remains; in the latter, it is destroyed, as indicated by the percolation of serum from the wound itself, and from mucous membranes of the individual bitten. Another remarkable circumstance connected with snake poisoning is, that venomous properties are by it communicated to the blood of the animal bitten, and that these properties become reproduced through a series of three successions of animals into which blood of this nature has been injected.

Among numerous other points of great importance brought out by Sir Joseph Fayrer are the facts that snake poison may be absorbed by mucous membranes and produce its effects; also that as a consequence, great danger attaches to the practice, so frequently recommended by writers on this subject, of applying the mouth to a snake wound and sucking the poison therefrom. Very grave doubts are also raised against the belief hitherto entertained that the poison is innocuous when received into the stomach. With regard to treatment, he observes that "there must be a quantity (of the poison), however small, which, though dangerous, is not of necessity fatal; and in such cases we may influence by treatment, and save life in some." Beyond this, neither he nor any other person practically acquainted with the subject holds out any hope whatever of an "antidote" against snake poison being found, and it is

well fully to recognise the conclusion thus arrived at after long continued investigation. The same conclusion has over and over again obtained confirmation. In the case of the great mass of the people in India most liable to be bitten by snakes, their innate apathy, added to their simple submission to *Kismet*, or faith, lead them to delay application for treatment until the time when treatment of any kind could possibly be of the slightest use, has long passed. When, therefore, we hear of recoveries having taken place, the true explanation lies in one of three circumstances—either the snake has been exhausted, or harmless, or it has bitten imperfectly. Whatever other differences there may be in results obtained by different investigators, there is unity of opinion that "the idea of finding a physiological antidote for snake poison is a Utopia."

ANTI-VIVISECTION AT OXFORD.

EVERY tolerant-minded graduate of the University of Oxford must have been exquisitely pained by the exhibition of virulent anti-scientific prejudice made in Convocation last week. The occasion selected for this outburst of feeling was that of confirming a grant for providing the sum of £10,000, to be spent in building and furnishing an appropriate working laboratory for the Waynfleet Professor of Physiology, Dr. Burdon Sanderson, F.R.S. Last summer, when the grant was first proposed, determined opposition was offered to it by a section of the University, and the majority of "placets" was at that time only three. Contrary to all expectation, the malcontents resolved to contest the vote when it came forward a second time, for confirmation, on the 5th inst.; and in order to ensure successful support secret information of the intention was circulated among non-resident members, that they might attend and reverse the previous decision. Fortunately, though at a late hour, information of this proceeding reached the Regius Professor of Physic, Dr. H. W. Acland, C.B., and he promptly acted on it to address a letter to the *Times*, exposing the whole conspiracy, and exhorting all who desired to witness progressive cultivation of science at Oxford to rally in defence of their principles. The result was a crushing defeat of the anti-progressionists, the votes being, for the grant, 188; against, 149.

This bare statement of facts might have been sufficient description of the incident, were it not for the miserable and underhand way in which attempts were made to coerce opinion to be adverse to the object in view; for the opponents of the scheme did not hesitate to call to their assistance the most disgraceful means of influencing the passion of bigots in favour of their pretensions. Together with the notices of the meeting, circulars descriptive of imaginary horrors committed by physiologists in pursuit of knowledge were freely distributed to known supporters of the opposition; and most unworthy attempts, not stopping short even at deliberate falsehood, were made in these productions to arouse a bitter feeling of resentment against the scientific party in the University. It is a peculiarly unhappy feature of the controversy, too, that so prominent an

official as the Bodleian librarian should have the reputation of being an active promoter of the propaganda, for this gentleman is openly spoken of as occupying this unenviable position. Indeed, the whole of the circumstances surrounding the incident are of a most ungrateful kind; and not least of all is it to be deplored that eminent scientific worthies like Dr. Burdon Sanderson should be subjected to floods of abuse at the hands of educated and otherwise honourable men, who would blush to act in private in the way they scruple not to do in the arena of University discussion. Few speeches more grossly intolerant and unjust have ever been pronounced than that in which the grant was opposed by the champion of anti-vivisection, who led the attack on this occasion; and in marked contrast to this were the calm and dignified utterances of Professors Acland and Burdon Sanderson, and of Dr. Liddell, Dean of Christ Church. The outspoken remonstrances of the latter were most appropriate and well-timed, and will, we trust have the effect of shaming the agitators into a future silence of long duration.

The outcome of the contest is an unqualified triumph for the cause of advance. Physiology, long cramped for want of space and due provision for its study, will now assume under Dr. Burdon Sanderson's energetic direction, that position at Oxford which at Cambridge has long been assigned to it. Such a result is one of the first towards restoring to their *alma mater* that proud pre-eminence in learning and research so ardently desired by every scientific member of the University of Oxford; and while congratulating themselves on the unqualified expression they have given to their aspirations they may well be content to await the development of those schemes for improvement which the grant now obtained will enable to be carried to completion.

Notes on Current Topics.

The London Hospital.

THE receiving-room of the London Hospital has recently been further furnished by the addition to it of a handsome case of polished pine, containing a complete selection of antidotes and remedies for immediate use in cases of poisoning. This consists of two portions, a cupboard with doors of bevelled plate glass, on the shelves of which reagents and drugs in liquid form are arranged; and beneath it a series of compartments shut by a drop lid, containing the other remedies demanded in emergencies. The exigencies of space have unfortunately compelled the cupboard to be fixed in a position where it is somewhat inconvenient to reach, but nevertheless it will probably be found a valuable acquisition by the resident staff in those frequent cases of accidental or intentional poisoning with which they have so often to deal in the discharge of their duties. Another improvement is the provision of a complete set of apparatus and reagents required for the testing of contents of the stomach and viscera, an important, but too often neglected, precaution in poisoning cases. This case will now be immediately available to house-surgeons and physicians, and should

be found of much service to them in simplifying and supplementing the evidence they may be called upon to give on such occasions as may arise to require it.

More about Kairin.

ALTHOUGH this drug is now being used more and more in this country, and many medical men have already made observations on it, some of which we may soon expect to see published, it is still from Germany that the greater part of our information regarding it comes. The readers of this journal for the last fifteen or sixteen months must be aware that it has already proved itself a certain, powerful, and safe antipyretic, but that its action varies somewhat in different individuals, and that in consequence, the proper dose for each person has to be ascertained by observation.

Dr. Guttman reports in the *Berliner Klinische Wochenschrift* that he has employed it in eighty-six different cases, that patients complained of the taste very much, so much so, that it had to be given in wafer paper or some such vehicle. In doses of 7 to 15 grains, he says, temperature was speedily reduced, and in many cases was normal $4\frac{1}{2}$ hours afterwards. The reduction of temperature is accompanied by profuse sweating. Sometimes vomiting was produced, ringing in the ears but rarely.

The rigor with which the rise of temperature is accompanied in some cases is proportionate to the degree of previous artificial reduction. The action of the drug is not diminished by use. The course of the disease is not in the least altered by the exhibition of the medicine.

Cohn and Zadek report in the *Deutsche Med. Wochenschrift* that kairin always succeeded in reducing febrile temperature, but they were not able to keep the temperature always low in continued pyrexia, nor did they succeed in remittent fever in preventing the exacerbation by giving the drug simultaneously with the commencing rise and repeating the dose hourly. In intermittent fever, and especially in the malarial form, even large doses did not cut short the attack.

Menche cannot recommend the drug in phthisis, typhus, or pneumonia, as collapse is sometimes observed as a consequence of its administration in the two latter affections. The results are more favourable in acute rheumatism. He thinks it may take the place of salicylate of soda in this affection.

Korach (*Deutsche Med. Zeitung*) would not recommend kairin in either typhus or pneumonia, as he observed marked collapses after its employment. He concedes, however, that it is one of the most certain antipyretics, but thinks it only suitable for hospital practice, as its concurrent effects require that the patient should be constantly watched, and the temperature taken every hour or two.

The Kildare County Infirmary.

THE presentment for the maintenance of the Kildare County Infirmary was—we are glad to say—carried last week by a majority of twenty to nine. This is the more gratifying, as nearly a successful attempt had been made last year by a section of the ratepayers to withdraw the grant and thus starve the institution out of existence.

Medical Reform.

WE have reason to know that the Medical Bill will be laid on the table of the House of Lords within a few days and will be sent down to the Commons at the very earliest moment that it can be got through its stages in the Upper House. Meanwhile, we believe that the Irish Colleges have made a move towards combined action to obtain amendments, and that it is not unlikely that the understanding which was effected last year between them and the Scotch corporations for mutual defence against the aggressiveness of the universities will be renewed. On the other hand the Royal Irish University has appointed a committee consisting of the Presidents of the Belfast and Cork Queen's Colleges with Drs. Banks and MacAlister to join hands with the delegates of Dublin University for combined action.

We greatly regret to observe these signs of approaching battle over the Bill, especially as we believe that the *casus belli* might be adjusted by a brief conference between Colleges and Universities in a conciliatory spirit. We are still more disappointed at the attitude which some of the enemies of reform in Ireland seem disposed to adopt, an attitude which, considering the obvious determination of the Government to pass the Bill against every opposition, seems to us as unwise as it is unjustified by the terms of the measure. A requisition has been presented to the President of the Irish College of Surgeons for a meeting of the College, and the object is believed to be opposition to the Bill, but, as the requisition is signed by Fellows all resident within one Irish county and probably not fully acquainted with the nature of the Bill, we have every hope that explanation will satisfy them that it is in the interest neither of the College nor of the profession to assume a hostile attitude. It is our firm opinion that if the licensing bodies are reasonable and practicable in their demands, they will be granted any concession consistent with the principles of the Bill, that any proposition—such as the ridiculous Huxley dogma—inconsistent therewith will not be even considered by Government, and that a policy of unyielding antagonism to the reform will simply end in the Colleges being put under foot and losing everything.

A New Departure in Medical Journalism.

OUR American contemporary, *The Medical News*, has, in its issue for January 26, essayed a new departure in professional journalism by admitting to its editorial columns a humorous article that would scarcely discredit the funniest of funny papers. The subject of this effusion is "Shortening the Duration of Pregnancy," and various reasons are given for interfering with the provisions of nature by robbing the growing fœtus of its last two months of intra-uterine existence. Droll and amusing as these arguments probably are, we fail just yet to see their appropriateness in a presumably scientific newspaper, the more especially as Americans of our acquaintance do not exhibit when "on travel" any remarkable evidence of being able to "spot a joke," without some clue. We fear, too, that a good many readers of the *News* will fail to supply for themselves the natural answer to our contemporary's query, why women carry children for a stated period the same in all normal

cases. The reason has been supposed on theoretical grounds to reside in an inherited proclivity, the absolute nature of which is maintained by the little probability of immature children surviving sufficiently long to become mothers themselves. The *News* makes various suggestions for hastening parturition, any one of which might with equal appropriateness have been left to the imagination of the speculative to conceive. As we have remarked, the article is funny, and "nothing more."

The Examiners of the Royal College of Surgeons, Edinburgh.

IN consequence of exception being taken to some recent remarks of ours on the protracted tenure of office by the examiners of the Royal College of Surgeons of Edinburgh, we have carefully prepared the following table from the Medical Directories for the last twenty years. It will be seen that of the twelve present examiners, six have held office for periods varying from thirteen to twenty years. Of the other six, three have been examiners for from six to eight years. Of the five examiners elected during the last twenty years, whose names do not appear in this list, three have resigned on becoming professors in Edinburgh and Aberdeen, one on election to the post of extra-mural examiner in the University, and the last on leaving Edinburgh, for we do not find his name in the Directory for 1884. One who resigned in 1882 from, we believe, increasing age, was eighteen years, and the other who died in 1881 seventeen years, an examiner, and a third had been fourteen years when he resigned. We have thus accounted for the vacancies on the life roll. We are, of course, aware that the form of re-election is gone through annually, but those best acquainted with the College know that this is purely a formal matter, as we think this table fairly testifies:—

Name.	Date of Election.	Died.	Re-signed.	Period of Office.
Archibald Inglis ...	1864	...	1882	18 years.
Peter D. Handyside ...	1864	1881	...	17 "
James D. Gillespie...	1864	...	...	20 "
Henry D. Littlejohn ...	1865	...	...	19 "
Patrick H. Watson...	1865	...	...	19 "
David Wilson ...	1866	...	...	18 "
John Smith...	1868	...	...	16 "
Argyll Robertson ...	1868	...	1882	14 "
Joseph Bell...	1871	...	...	13 "
John Duncan ...	1876	...	...	8 "
R. J. Blair Cunyngnam ...	1876	...	...	8 "
Alexander G. Miller ...	1878	...	...	6 "
Johnston Symington ...	1882	...	...	2 "
Peter H. Maclaren...	1882	...	...	2 "
F. Cadell ...	1883	...	...	1 "

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 26, Paris 25, Geneva 25, Brussels 24, Amsterdam 31, Rotterdam 27, The Hague 21, Copenhagen 23, Stockholm 25, Christiania 16, St. Petersburg 37, Berlin 24, Hamburg 24, Dresden 26, Breslau 30, Munich 29, Vienna 26, Prague 35, Buda-Pesth 26, Venice 27, Lisbon 37, New York 23, Brooklyn 22, Philadelphia 22, and Baltimore 24.

The French Crusade against American Bacon.

DR. PAMETIER, Director of the Natural History Museum at Rouen, has communicated to the Paris Academy a series of twenty experiments made by him for the purpose of ascertaining the transmissibility of trichinæ from pork to living animals. The pork which he experimented with contained eight or ten trichinæ to each cubic millimetre all alive, and he caused it to be eaten uncooked by twenty rabbits and rats. In not one of the animals did he find any depreciation in health whatever, and, having killed them, he found their muscles entirely free from the trichinæ which, on opening the cysts, were found to be dead. He concludes that in these instances the ingestion of the trichinous meat was entirely harmless, but he proposes to repeat the experiments under other conditions, in order to avoid the possibility of error.

The Irish College of Surgeons and the Medical Bill.

A REQUISITION has been presented to the President of the College to convene a meeting of the Fellows, to consider the provisions of the Medical Act Amendment Bill, and its probable effect on the College should the said Bill become law. The requisition is signed by the following Fellows:—James Molony, Edward O'Kelly Nolan, Daniel Molony, Thomas Foley Brew, Robert Barry, Maurice D. O'Connell, Francis W. O'Connor, Thomas Darby, Thomas S. Whistler, Michael J. Malone, Zacharia Johnston, Francis J. O'Reilly, David Hadden, James F. Pollock, Robert M. Tagert, William D. Hemphill, Abraham Kidd, J. Bellew Kelly. The meeting will be held on Friday next, February the 15th, at one o'clock precisely.

Dental Diplomas sine Curriculo.

WE regret to learn that the Council of the Irish College of Surgeons has decided to keep the portals of that institution open for admitting to the Licence in Dentistry persons who do not make any pretence of having learned their profession. The College, it will be recollected, availed itself of the passing of the Dental Act to establish a "year of grace"—as that period of laxity is called—during which diplomas can be had by all comers who choose to pay for them and pass a nominal examination. That year has long since expired, but the College, having tasted the sweets of unlimited diploma-granting, did not hesitate to violate its engagement with the General Medical Council that it would cease admitting uneducated persons, but has since continued, and avows its determination to continue, the issue of its licences to such persons as long as one man of the 4,000 hairdressers, tobaccoonists, and druggists' boys remains on the Dental Register who is willing to pay for the honour (!) The College would probably say that, in restricting its diplomas to those on the Dental Register, it sufficiently guards its own dignity; but we all know that the presence of a candidate's name on that list would be generally accepted by respectable dental surgeons as *prima facie* proof that the registrée is not either socially respectable or decently educated. But even if these *sine curriculo* candidates were

of the class likely to do credit to the College, we should object to the traffic with them for dental diplomas, for the continuance of that traffic is a clear admission by the College that it does not regard education or antecedents as essential qualifications to obtain its licences. We believe that a sort of form is gone through by the College of receiving testimonials of character from each candidate, and taking from him an undertaking not to advertise, but as we are aware that many of the licentiates have unhesitatingly broken, and continue to break, the latter undertaking, and as it is obviously impossible that the College can have the least knowledge of either the testimonialised or the testimonialisers, we look upon this process as a sham and a cover for the subsequent grant of a diploma. It is our deliberate opinion that the Irish College of Surgeons has been disgraced by this traffic.

The Parkes Museum.

CAPTAIN GALTON, C.B., F.R.S., presided at the opening of the spring session at the Parkes Museum on Thursday, January 31st, when Mr. H. A. Darbishire, F.R.I.B.A., read a paper on "Artisans' and Labourers' Dwellings." Mr. M. H. Judge, A.R.I.B.A., a Director of the Artisans', Labourers', and General Dwellings Company, proposed the following resolution, viz.:—"That the Council of the Parkes Museum be requested to appoint a Special Committee of medical men, architects, and engineers to inquire into, and report on, the condition of the dwellings of the poor." Mr. H. Rutherford, member of the council of the Sanitary Assurance Association, seconded the resolution, which was passed after some further discussion, in which Dr. G. V. Poore, Vice-Chairman of the Parkes Museum, referred to the overcrowding existing among the residents of Soho, where the dwellings of the wealthy of a century ago were now occupied by the poor.

At a meeting of the Royal Society of London, recently, five foreign Honorary Fellows were elected, among the number being Professor Rudolf Virchow.

THE Scotch Universities Bill will be reintroduced at an early date. The provision relating to the Chairs of Theology will, it is expected, be retained, but the clause pointing to the possible extinction of St. Andrew's University will be modified, or dropped altogether.

IN view of the probable resumption of naval operations in Egypt, the following appointments have been gazetted:—Staff-Surgeons: James H. Martin, to the *Euryalus*, and William B. Drew, to the *Alexandra*; and Surgeons: Michael J. McCarthy and Nicholas C. Ross, to the *Alexandra*, for service with the Marines in Egypt.

DR. CAMERON has secured the 30th of April for the second reading of his bill in the House of Commons regulating cremations. The bill has for its object the strict supervision and regulation of all crematoriums, public or private, which may be established in the country. At present cremations may take place, as they are not forbidden by law.

Vivisection in Germany.

THIS subject was again debated in the Prussian House of Representatives on the 29th ult., the Cultusminister taking the same ground as on previous occasions, viz., against limitation of vivisection by the State. As we reported in a former issue, the various Universities were required to send in for the guidance of the Government their views on the subject, and as will have been expected, these were not in favour of limitation. The Minister leaves it to Science to draw its own boundaries, and to say how far research by experiment is necessary. Applying to one celebrated Professor of Physiology for information, the gentleman gave his answer in a sufficiently concise and *striking* manner. Taking up the last edition of Hermann's "Handbook of Physiology," he struck his pen through all those parts of the work that were based on experimental research or in any way indebted to it. The result was that not more than one-fourth of the book remained uninjured! The lesson was not taught in vain, and the important result given above may be due in great measure to the great aptitude for teaching thus shown by the distinguished professor. Have we no professors who can teach, or are our legislators and ministers above being taught?

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 20.5 per 1,000 of their aggregate population. The death-rates in the several towns were:—Derby, Cardiff 13; Leicester 14; Birkenhead, Norwich 16; Huddersfield, Hull, Preston, Halifax 17; Bradford, Bristol 18; Liverpool, Blackburn, Plymouth, Salford 19; Sheffield, Nottingham, London, Birmingham 20; Bolton, Portsmouth 21; Edinburgh 22; Glasgow, Brighton, Wolverhampton, Manchester 23; Newcastle-on-Tyne, Leeds 24; Sunderland 25; Oldham 28; Dublin 29.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class were—From whooping-cough, 3.4 in Bolton, 1.4 in Manchester and in Newcastle-upon-Tyne, and 1.1 in London; from scarlet fever, 4.5 in Leeds and 1.9 in Sheffield; and from measles, 1.9 in Salford and 1.2 in Derby. The 40 deaths from diphtheria included 23 in London, 3 in Leeds, 3 in Hull, and 2 each in Dublin, Glasgow, and Birmingham. Small-pox caused 7 deaths in Birmingham, 3 in Liverpool, 2 in Sunderland, 1 in London, and 1 in Wolverhampton.

THE extent and readiness with which the trade in poisons is carried on in England may be judged by perusal of the report of an inquest held last week at Worcester, from which it appeared that a local chemist had sold without hesitation sixpennyworth of prussic acid to a woman whose name he did not know, who was not introduced by anyone (as required by the Act), and who stated at the time that she did not know the drug was poisonous. The chemist admitted that he knew of no purpose to which the acid could be put except for poison; and the woman did straightway poison herself and her child. Nevertheless the chemist escaped without even a censure.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

"THOUGHT-READING" IN GLASGOW.—The latest phase of "scientific" humbug with which poor Scotland has been afflicted is that species of jugglery termed, in a very misleading fashion, "thought-reading," and which seems to possess a special fascination for certain Scotch professors. On Thursday week that well-known medium, Mr. Stuart Cumberland, who must by this time have practised what he is pleased to term his "art" with most profitable pecuniary results to himself, gave a *séance* at the George Hotel, Glasgow. Among the audience were seen Drs. Simpson, Yellowlees, Smith, and Wolfe, but these proved very bad media for Mr. Cumberland. Before proceeding with his illustrations, Mr. Cumberland said his object was to show as clearly as possible certain phases of so-called thought-reading. He made no pretence of reading mental pictures, because he did not think it was possible to see into the mind of any man. If, however, any person thought upon a given object, and concentrated his attention upon it, it was possible for a person with a very keen sense of perception to interpret that man's ideas. After one or two unsuccessful attempts the medium requested Professor Simpson to hide a pin, and Dr. Munro an article of value. Mr. Cumberland left the room, and returning took Prof. Simpson's hand, but failed to find the pin, which was hid in the back of his necktie. Remarking that doctors were bad subjects, and complaining of weariness and of the intense heat of the room, Mr. Cumberland took the hand of Dr. Smith, and placing it to his brow, carefully searched the chair, sofa, carpet, and other articles in the room, but had to give up the search. Taking Dr. Munro's hand, Mr. Cumberland then went almost direct to the sideboard, lifted an ornament, opened a book which lay under it, and took out the coin. The next medium was Dr. Marshall Lang, with whom Mr. Cumberland without much difficulty found the place in the edge of the carpet at the door, where a pin had been hidden, but which had somehow slipped below the carpet. The next experiment was one of a different character, viz.—to remove a certain article, thought upon, from one part of the room to another: with the Rev. Dr. Lang as the medium Mr. Cumberland with little hesitation removed a brush from a peg beside the mantelpiece and laid it on the sideboard. Again Mr. Cumberland tried the medical men, but though he remained some time in the neighbourhood of a tumbler of seltzer water, he failed to discover that it was the object on which Dr. Yellowlees had concentrated his thoughts. With Professor Simpson he was equally unsuccessful. Both these gentlemen assured Mr. Cumberland that, while giving him no facilities to find the object, they had done nothing wilfully to hinder the search. We can well understand the interest of Dr. Yellowlees in such a subject, and if his presence with the other members of the profession at this *séance* shall have contributed to the exposure of an imposture some good may result therefrom.

THE EXAMINERSHIP ON FORENSIC MEDICINE IN THE UNIVERSITY OF EDINBURGH.—We congratulate Dr. Littlejohn on his appointment of Examiner in the University after so many years of neglect, and we are gratified that our continued advocacy of the claims of the Extra-Mural School have at last borne good fruit. Dr. Littlejohn is, we believe with one exception, the only lecturer in the Extra-Mural School who has been appointed to examine on the same subject as the one on which he lectures.

AMBULANCE WORK.—On Saturday, the 2nd inst, Dr

Beaton, Glasgow, delivered a lecture in the Free Assembly Hall, Edinburgh, on City Ambulance Work, and the desirability of establishing ambulance classes. Bailie Clark presided over a very large audience. The lecturer began by pointing to the great number of accidents which daily occurred in crowded cities; how the greater proportion of them were wholly unforeseen; and how many of them terminated fatally, or how many of them became much more serious than they might have been, simply from a want of knowledge of proper immediate treatment on the part of those who first came into contact with the person or persons injured. He urged the establishment in Edinburgh of an ambulance association, such as the St. Andrew's Ambulance Association of Glasgow, and of well organised ambulance classes, in which people might be thoroughly trained to treat accidents as they occurred. The lecture was illustrated by diagrams. An attendant at the Glasgow ambulance office, and a number of pupils who were present, went through several exercises, with the view of showing how persons should be at once treated who receive such accidents as are of almost everyday occurrence, and how materials lying about can, with method and knowledge of the subject, be utilised in alleviating pain or in removing the patient to the care of the surgeon. The lecturer was frequently applauded, and at the close, on the motion of the Chairman, received a vote of thanks.

THE SANITARY CONDITION OF BAKEHOUSES.—The Board of Supervision have issued an order calling the attention of Local Authorities to certain provisions in the Factory and Workshops Act, 1883, which came into operation on the 1st January. The Act provides for the inspection of bakehouses by inspectors under Local Authorities, and for the infliction of penalties for letting or using as bakehouses premises the sanitary condition of which do not comply with the requirements of the Act. As respects retail bakehouses, the provisions of this Act, and of the sections of the Factory and Workshops Act, 1878, which relate to cleanliness, ventilation, overcrowding, and other sanitary conditions, shall be enforced by Local Authorities; and for the purposes of this section medical officers of health of Local Authorities shall have all such powers of entry, inspection, and of prosecution as an inspector under the Act of 1878. "The Board," it is added, "are of opinion that it will be necessary for the due enforcement of the Act that the Local Authority should instruct their medical officer, either personally or by an authorised assistant, to visit and report on the various bakehouses within the district of the Local Authority. The Local Authority will thus be in a position to take the proper steps for securing that the provisions of the Act are systematically and efficiently enforced."

EDINBURGH ROYAL HOSPITAL FOR SICK CHILDREN.—The directors of this hospital, at their meeting on the 4th inst., elected Dr. John Playfair to be one of the ordinary physicians, in room of Dr. James Dunsmuir, jun., whose term of office has expired. The directors are to meet on the 25th inst. to appoint an extra physician to the vacancy caused by Dr. Playfair's promotion.

GLASGOW.—RELIEF OF INCURABLES.—The ninth general annual meeting of contributors to the funds of the Association for the Relief of Incurables for Glasgow and the West of Scotland took place last week. Lord Provost M'Onie presided. The report, which was read, showed that of the 74 patients in the home during the year, 8 had died and 4 were removed by friends. Of 189 outdoor pensioners, 28 had died, 3 were struck off the roll, and 1 went to the poorhouse. Since its formation in 1875 the Association had assisted as out-patients

493 incurably afflicted sufferers with pensions averaging about 10s. monthly, while 168 had been admitted to the home. For last year the income amounted to £3,851 3s. 11½d., besides several legacies, added to capital, the expenditure being £3,858 16s. 10d. The report and abstract of accounts were adopted, and the retiring directors were re-elected.

AUSTRIA AND THE EDINBURGH UNIVERSITY TRICENTENARY.—The Senate of the University of Vienna, in reply to an invitation from the University of Edinburgh to attend the forthcoming tricentenary celebration, has decided to send a complimentary address on the occasion.

GLASGOW UNIVERSITY MEDICAL BALL.—The annual ball of the students attending the Medical Faculty of this University took place on the 6th inst., in the Queen's Rooms. The ball was the most successful of any held under the same auspices, the attendance numbering over 350. Several of the University professors and other medical friends attended.

AYR.—LEGACY TO THE COUNTY HOSPITAL.—It is stated that the late Mrs. Dixon, of Belleisle, has left £1,000 to the Ayr Hospital. A few weeks previous to her death Mrs. Dixon sent a cheque for £500 to the same institution.

SCOTCH VITAL STATISTICS.—From the official returns of the Registrar-General, we learn that the death-rate in the eight principal towns during the week ending with Saturday, February 2nd, was 22·4 per 1,000 of estimated population. This rate is 3·9 below that for the corresponding week of last year, but 2·3 above that for the previous week of the present year. The lowest mortality was recorded in Dundee, viz., 16·3 per 1,000; and the highest in Aberdeen, viz., 27·6 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 2·8 per 1,000, being 0·3 below the rate for last week. Acute diseases of the chest caused 111 deaths, being 20 above the number recorded during the previous week.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 2nd inst., was 102, and the death-rate 22 per 1,000. Diseases of the chest accounted for 50 deaths, and zymotic causes for 13, of which 2 were due to fever, 3 to scarlatina, and 5 to measles.

THE PROFESSORSHIP OF BOTANY IN THE UNIVERSITY OF GLASGOW.—By the appointment on Friday last of Professor Isaac Bayley Balfour, F.R.S.E., to the Sherardian Professorship of Botany in the University of Oxford, the Regius Professorship of Botany in the University of Glasgow became vacant. Professor Balfour was, in 1879, appointed Crown Professor of Botany in the University of Glasgow, and gained First Class Honours in Botany, and has had practical direction of the Glasgow Botanic Garden and Herbarium. He was in 1874 appointed by the Royal Society Botanist and Geologist to the Transit Expedition of Rodrigues, and in 1880 made a scientific exploration of the Island of Socotra. A Fellowship of Magdalen College is now attached to the Professorship, and the combined emoluments of the office will be £500 a year, with residence and other privileges.

Correspondence.

THE SCOTCH CORPORATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The attention of the Royal College of Surgeons of Edinburgh has been directed to a leading article in the columns of your journal of 16th ult., under the head of "The Scotch Corporations and Impending Legislation." In that article it is stated that "The examinations of the corporations

are conducted in a most secret manner, and it is only by stealth that the questions set at the written part of the examinations are made public. Certain persons are it is true appointed as Assessors, but these are carefully selected by the Corporations themselves and not by the Government; and we have no record of their being ever present at any of the examinations. At present also some of the examiners are elected for life; some have been in possession of the post for twenty or more years. This state of matters is neither fair to the student nor of advantage to the profession, and it is absurd that candidates should be taught the principles of modern medical science and examined by men whose generation has ceased to exist except in a more or less fossilised condition."

The plural number being used throughout the article, this College is presumably included in your strictures, and I have to point out to you that so far as regards it, the article above quoted contains statements contrary to fact. For example, the statement that "At present also some of the examiners are elected for life," is unfounded, and on behalf of this College I have to call upon you in the next impression of your journal to withdraw the statement.

The writer of the article referred to does not appear to understand the position or function of the Assessors here, but I do not think it necessary to explain the duties of the various office-bearers, which are well enough known to all having any interest. It is surprising that you should have made such a statement in view of the fact that for many years past I have regularly forwarded to you an annual advertisement of the election of the whole of the office-bearers of the College, which has been as regularly inserted in your journal.

The further allegation contained in your article in the following terms, "To procure candidates, and to invest the fees obtained from them in sound securities has been, and is, the one idea which permeates the whole life of the Scotch Corporations" is simply a slander, which will do more injury to the party making it than to those against whom it is directed.

At page 59 of the same number of the journal there are certain editorial remarks annexed to a letter by Dr. George H. Kidd. In these remarks you say, "We know in fact, that the Irish student does not go to Scotland to seek a double diploma, and therefore that he would not be enticed to remain at home if one were provided for him in Dublin. He goes to Scotland to seek a Licensing Body who will take him on a two year curriculum, three years under the old system, and four years' under the new system being the least times within which he can qualify in the Irish Colleges. As long as this difference of the indispensable period of study remains, so long will the Irish student go to Scotland. He does not want to save a few pounds in the diploma fee, or to get rid of a redundancy of examinations, but to save a year's residence at the Dublin schools, and a year's delay in entering practice." The sentence now quoted betrays ignorance on the part of the writer of the requirements of the Scotch Corporations. These Corporations require a four years' curriculum (not two years), as represented in the remarks. This ignorance seems quite inexcusable when it is kept in mind that the Regulations of these Corporations showing their requirements have long been regularly sent to you, in common with the other London medical journals, for insertion in the Students' Numbers of these journals. In particular I may refer you to the Students' Number of your paper of 19th September last, page 258, where in an abstract of the Regulations of this College under the head of "Professional Study" you gave the information that "Candidates must have been engaged during four years after the Preliminary examination in general education in professional study which shall include not less than four winter sessions, or three winter and two summers' attendance at a recognised medical school."

I think you will agree with me that in these circumstances it was highly culpable to publish in your journal a statement so inaccurate and misleading, and which is calculated to give the impression that the writer was not disinclined to make depreciating remarks regarding the Scotch Corporations.

In the next page of the number of your Journal of the 16th ult. there is a letter signed "H. Aubrey Husband," dated 12th ult., in which the writer, after disclaiming admiration for any of the Corporations, informs your readers that "in Edinburgh grinding is not absolutely necessary, although it is as well to know the views of men who for the last twenty years have annually elected themselves as examiners, and will continue to do till death stops the process. The Edinburgh College is not immaculate, but its sins are not greater than other Corporations, which perhaps is not saying much, but

still it is something, and it is only fair that in the coming struggle justice should be dealt to those venerable, but now apparently unnecessary institutions." This I presume is the statement of a gentleman who is known here, and I must express surprise that with the knowledge which he cannot fail to have of the facts as regards election of examiners here, he should have made that statement which is entirely misleading. There is no self-election of examiners in this College. The following is the law on the subject:—"At the same meeting" (the annual meeting specially called for the purpose) "each Fellow present shall give a signed list to the secretary containing the names of twelve Fellows for performing the duties of examiners for the ensuing year; all of whom must have been Fellows of the College for the space of one year. At the same meeting a committee of two Fellows shall be named to examine the lists along with the Secretary, and the twelve Fellows who are found to have the greatest number of votes shall be reported to the meeting, when they shall be declared examiners for the ensuing year."

I have to request you to publish this letter, or at all events in your next issue make the necessary corrections upon the statements now objected to.

I am, &c.,

JAMES ROBERTSON,
Clerk of the College.

[WITH regard to our remarks on the secrecy of the examinations, we may state that every candidate is required to give up the questions set, and this has been rendered necessary by the fact that the papers have been, till only recently, used over and over again at the examinations. If a request be made for a copy of the previous questions the application is refused, except in the case of the Glasgow Faculty. The table which we publish in another column of the tenure of office of the examiners of the Royal College of Surgeons is, we hope, a sufficient answer to the objections taken to our remarks and those of our correspondent. We have no doubt that the election is nominally annual, but from our investigations it appears to be virtually for life. We believe that none of the Corporations are free from the influence of cliques, a remark which does not apply in the case of the Edinburgh College of Surgeons more than to other bodies. If, however, the returns of the election of examiners at this College be taken, it will be seen that vacancies have only been filled up by the death or resignation of the examiners, those last elected being placed at the end of the list and moving up as those in front of them were removed in the manner indicated.

With regard to the one idea of the Scotch Corporations, we regret to have omitted that of throwing every obstacle in the way of the Government towards legitimate medical reform (deplored by Sir Lyon Playfair in our last issue, page 126), and now hasten to make the correction. We believe that for this purpose the Scotch Corporations spent last session between £1,600 and £2,000, and are prepared to repeat the expenditure.

With reference to the objection taken to our reply to Dr. Kidd, we may remark that we are fully aware that the Scotch Colleges, in common with almost all other licensing bodies, require by their official regulations that the candidate shall have been engaged for four years in medical study; but we are also aware that—not more, perhaps, in Scotland than elsewhere—that requirement is systematically evaded by the student, and that, to a certain extent, the defined period of medical study is a sham. We all know that a certificate of pupillage with a practitioner—which can be readily obtained by any student—stands with most licensing bodies for one of the four years, and that credit for one other year is easily obtained by a shuffle of certificates, of which we must suppose the Colleges are unconscious. The only *bona fide* period of study is, speaking generally, that which is spent in a school; and as the Scotch Colleges only require such certificates as can be obtained in two school years, we assert that two years is, in many instances the true period of study of their candidates.

nyone looking to the regulations of the Edinburgh College of Surgeons, will observe that the maximum extent of any course is twenty-four months, and furthermore, that the sequence of study extending over four years is "recommended as a guide to the student, though not enjoined."

As a matter of fact it is notorious that numbers of Irish students who had obtained the two years' certificates necessary for the Scotch colleges, but insufficient for the Irish colleges, did—and so far as we know—do resort to the former, and obtain their licenses in respect of that period of study, because they thereby avoid the third certificate in certain subjects required by the Irish Colleges.

We commend to the perusal of the Scotch colleges the evidence before the Royal Commission of Mr. W. Stoker of Dublin, (pages 269-274) from which we cull two excerpts—

Question 5,147.—Is there much variation in the time recognised by various licensing bodies in order to obtain degrees?—Very great variation. Some licenses are obtainable in a minimum time of two years and five months. In some the Medical Council's suggestion of four years is, I believe, rigidly carried out. The ideal time in most of them is four years. I say "ideal" because in some cases the modes recognised as the commencement of medical work are so numerous and elastic under slight strain as to be practically valueless.

Question 5,219.—Are we to understand that one great reason for students going to Scotland is because the curriculum of the Scottish corporations closely approximates to that of the Queen's Colleges?—Yes.

Question 5,220.—And that, therefore, a course of study pursued in the Queen's Colleges fits a man for examination at the Scottish corporations where it does not fit him for examination before the Irish College of Surgeons?—Yes.—*Ed.]*

MEDICAL ACT AMENDMENT BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Now that we are informed it is the intention of the Government to re-introduce the Bill of last Session, and if possible, push it forward to enactment, it behoves us to carefully examine its tendency and bearing, and as after a very careful examination of its clauses, I have formed a most unfavourable opinion of the Bill, I feel bound to express that opinion, and to explain my reasons for holding it.

It appears to me that the enactment of such a measure would be destructive to the Colleges of Physicians and Surgeons in Ireland, institutions, a large proportion of which are acknowledged to have done their work "wisely and well," showing "a praiseworthy readiness to introduce improvements in their examinations, whether originated by themselves or suggested by the General Medical Council," and under whose fostering care "the educated medical body of the United Kingdom is a better educated medical body as a whole than any that exists in the world."

I believe that any measure that would destroy institutions so working would be injurious to the public welfare, and to the best interests of the community at large.

It appears to me further that the enactment of such a measure would lower the standard of education, degrade the status of the profession, and retard the progress of medical science; and I believe all the benefits sought for by the proposed legislation could be obtained without the infliction of such great evils.

I shall first deal with the Bill as to its effects on the Colleges, and show how it is proposed to strip them of their functions and privileges, and leave them as Dr. Barton has said "high and dry, interesting as wrecks of a bygone time, but slowly settling down into the sand and mud of uselessness and poverty."

I have before me the Bill "ordered by the House of Commons to be printed, 2 May, 1883." This is the last edition, that which was to have been presented to the House of Commons for a second reading, and we may assume the form in which the Bill is to be brought forward next session. The points to which I wish to draw attention are contained in the clauses in reference to—1. Medical Boards; 2. Medical Education; 3. Medical titles, Medical

Register, and Medical Authorities; 4. Expenses and Medical Funds.

1. *Medical Boards.*—The Bill proposed to establish three Medical Boards, viz., one for England, one for Scotland, and one for Ireland. These Boards were to be elected by the Universities and Colleges in the respective countries. The members of the boards were not necessarily to be medical men. "Any person of full age shall be qualified to be elected a member of a medical board," and "the same person may be a member of more than one medical board." The boards were to be renewed every five years by the retirement of all their members and the election of others.

The Medical boards thus constituted partly, it may be, of laymen and partly of medical men, possibly indeed under the Bill all laymen, and some of them to a certainty to be elected by bodies when the medical profession would scarcely, if at all, be represented, were to supersede the present "medical authorities" in many or all of their most important functions.

The Medical board of each part of the United Kingdom was to work a scheme or schemes providing for the following matters:—

"1. The holding, at such times and places as may be most convenient, Final examinations in medicine, surgery and midwifery for the admission of candidates to registration as medical practitioners; and

"2. The appointment of examiners for such examinations; and

"3. The nature and conduct of such examinations, and the qualification of candidates as to age, moral character and any other matter necessary or expedient to be determined by rules in relation to such examinations."

The rules with respect to "Final examinations" were "to be framed in such manner as to secure as far as practicable in each part of the United Kingdom an equality of standard in each Final examination."

"At the conclusion of each Final examination, the Board were to certify to the Medical Council the persons who had passed with such credit as to entitle them to be registered as medical practitioners."

From this statement, taken from the Bill itself, it will be seen that the Medical boards were to perform almost all the duties hitherto performed by the Colleges, for the performance of which the Colleges were instituted, by the performance of which they lived, and by their performance of which they made the educated medical body of the three kingdoms the best educated medical body in the world. And why are the Colleges to be superseded in this wholesale manner, because, forsooth, some three of the present licensing bodies are said not to have performed their duties as well as they ought to have done. And in certain cases the possession of a diploma affords no guarantee that the practitioner possesses a competent knowledge of medicine, surgery, and midwifery.

After an inquiry extending over more than a year, and hearing a mass of evidence, the report of which fills a Blue book of more than 400 folio pages, these are the only tangible defects in the present system that the Commissioners have been able to assign for their proposals. Would not such legislation fairly come under Prof. Huxley's denunciation as an "unjustifiable employment of the authority of the State." "To strip," he says, "a large proportion of medical authorities of privileges which they can be shown to be using well and wisely, because of the abuses which obtain among a small minority does not appear to me to be justifiable employment of the authority of the State." These it must be remembered are not hasty or ill-considered words, they were written, after hearing all the evidence given before the Royal Commissioners, as a protest against the recommendation of such legislation, and they have been endorsed as such by four out of the eleven Commissioners.

But let us proceed to consider the further duties assigned to these Medical boards: In the section on "Medical Education," "it shall be the duty of each Medical board to make," it says, "a scheme or schemes with reference to the following matters within the part of the United Kingdom to which such board belongs, that is to say:—

"1. The preliminary examinations for the admission of persons applying to be admitted as medical students.

"2. The course of medical education in this Act referred to as the prescribed course.

"In defining the prescribed course of medical education the scheme shall describe—

"a. The schools in the United Kingdom or elsewhere (in this Act referred to as recognised medical schools) which are to be considered proper places of education for medical students as respects the whole or any part of their medical studies; and

"b. The times and places at which examinations are to be held for testing from time to time during the continuance of the prescribed course of medical education the proficiency of the students in their various branches of study; and

"c. The authorities (in this Act referred to as recognised examining authorities) who are to be considered competent for conducting or for appointing examiners to conduct such examinations as are in this section mentioned."

Now let us see what are the privileges of which the medical authorities were to be stripped by "an unjust employment of the authority of the State," privileges which they can be shown, says our Royal Commissioner, to be "using well and wisely."

1. The holding of Final examinations.
2. The appointment of examiners for such examinations.
3. The making of rules for the conducting of such examinations.
4. The granting of licences entitling to registration.
5. The arrangement of the preliminary education and examination of medical students.
6. The prescribing of the course of professional education.
7. The licensing or recognition and supervision of medical schools as places of instruction.
8. The holding of primary or sessional examinations.
9. The appointment of examiners for conducting primary or sessional examinations.

Here is a stripping of privileges with a vengeance, privileges which have been used "well and wisely," by the exercise of which "the educated medical body of the United Kingdom has been made the best educated medical body in the world." Well might your correspondent "F.R.C.S., ex-President of the Irish Medical Association," say our Colleges are to be disestablished—disestablished, indeed, and disendowed too, as I shall now show.

In Part V., "Expenses and Medical Funds," it is proposed that each medical board may charge such fees for its examinations and for the registration of medical students "as with the assent of the Medical Council and the sanction of the Privy Council they may determine." Thus, they are to charge fees for the "examinations"—not for the Final examination only, but for the examinations; and out of these they are to pay—

1. The expenses of the examination.
2. To pay themselves for attending the board meetings.
3. The office expenses.

And all these items being paid, they are to give an obolus to the medical authorities for the maintenance of their museums and libraries.

Thus are the medical authorities not only to be disestablished, but disendowed too, "left high and dry, interesting as wrecks of a bygone time, but slowly sinking down into the sand of uselessness and poverty."

What, it may well be asked, is there left for the "medical authorities" to do?—for what are they to continue to live? In a recent number of your journal (Dec. 5, 1883) you give what you call "a brief outline of the Medical Bill of last year, to which we presume the Bill of the coming session will be assimilated." In this you point out that the boards are to be formed by delegates from the licensing bodies. Here there is one privilege they are to be given. Once in every five years they may elect two or three delegates each, to form the Medical Board, and having done this they may close their doors and pass into a state of torpor for the following five years, only to be disturbed by the appearance at rare intervals of a candidate for their Fellowship.

But perhaps I am making a mistake, for I find you assert in the outline referred to that one of the duties of the new Board will be "to supervise primary examinations, which will continue to be held by the licensing bodies."

But where, I ask, is the provision for this in the Bill? I assert there is no such provision. I go further, and say the privilege, humble as it is, has been expressly removed from the Bill. As originally introduced into the House of Lords, the Bill contained a clause by which the Colleges might have held these sessional or primary examinations, a privilege nearly equivalent to that of a nursery governess who prepares children for the more advanced teachers, but under the Bill as it came to the House of Commons even this privilege has been taken away. I have already given the clause (c) as it stands in the last edition of the Bill. Let us compare it with the

same clause in the Bill as it was introduced into the House of Lords:—

"(c) The authorities (in this Act referred to as recognised examining authorities) who are to be considered competent for conducting or for appointing examiners to conduct such examinations as are in this section mentioned" (i.e., the sessional or primary examinations), "and such examining authorities may be all or any of the following authorities, that is to say, the Medical Board themselves or any medical authority in the United Kingdom or elsewhere."

Here the Boards themselves are given the power to hold these sessional examinations as well as the final, but if they do not choose to monopolise all the examinations, then out of their magnanimity and condescension they may allow the "medical authorities" this great privilege.

By the term "medical authorities" is meant the various universities, colleges, and licensing bodies throughout the Kingdom. The term was so defined in the Bill introduced by the Marquis of Ripon in 1870, and has been so used ever since. But we have here a new phrase—"examining authorities"—introduced, a phrase never used in medical legislation before. In the Bill as introduced into the House of Lords, an interpretation of the phrase was given as meaning the Medical Boards and the universities, medical colleges, &c. Why has the interpretation been out of the clause? Simply because it preserved for the Colleges the privilege of holding those examinations if the Boards did not think it becoming their dignity to themselves hold them. Nor are we left without confirmatory evidence as to the truth of this view of the meaning of his omission. The British Medical Association has, we all know, taken a most active part in the agitation for this Bill. Its enmity to the Colleges has never been concealed. In Oct., 1880, the Association appointed a committee to report on medical education. The report was published in January, 1881. It recommends that before the commencement of their second year candidates should be required to pass an examination in their first year's studies, that is, a "testing examination," as it is called in the Bill; or, as I have called it, a "sessional," or primary examination. The committee would be content with one testing examination to be held at the end of the first year, and they say, "This first professional examination should be held at the School, or other convenient place." "Such examination," they say, "should be conducted essentially by the qualifying authorities, aided by, but not superseded by, the teachers at the school." "The qualifying authorities"—the Medical Boards—they hoped to get appointed were to send an examiner to each school to hold such examinations. The framer of the Bill as introduced into the House of Lords did not take in the whole bearing of the case, and left the Colleges this poor relic of their privileges, but the mistake was soon detected, the definition of the new phrase was withdrawn, and the way was left open for the more complete stripping of the Colleges of the privileges which it could not be denied they had for the most part used "wisely and well."

This, however, is not the only erroneous statement in your "outline" of the Bill. In paragraph No. 3 you state—

"Licensing bodies will continue to grant diplomas on any terms they please (subject to the supervision of the Board), but these diplomas will not be registrable; they will, however, be necessary for any one going for the final examination of the Board."

I quote the very words, italics and all. It is a most important statement. If such a provision were in the Bill the Colleges might live and continue to confer many of the great benefits they have hitherto conferred on the community and on the profession. But again I assert there is no such provision in the Bill. The statement is erroneous and misleading. Under the Bill candidates may present themselves for the final examination of the Boards who have never entered the doors of any medical authority, college, or licensing body. So far from "a diploma being necessary for anyone going for the final examination of the Board," special provision is made in the Bill to make it unnecessary. Anyone who wishes to call himself "Doctor," "Surgeon," or "Apothecary" must indeed become a Doctor, Surgeon, or Apothecary; but anyone may be a "Registered Medical Practitioner" and enjoy all the rights and privileges of the profession, and though he cannot himself assume titles, he can be called Doctor or Surgeon by others to his heart's content without having ever contributed one fraction to any "medical authority," "college," or "licensing body," or entered their doors, or what is still more important, affiliated himself to them either for discipline and mutual sup-

port, protection, and instruction, or the advancement of professional or scientific knowledge.

I am, &c.,

GEORGE H. KIDD,
Past President of the Royal College of
Surgeons in Ireland; of the Irish
Medical Association; and of the
Dublin Branch of the British Medical
Association.

[SPACE does not permit us to criticise our correspondent's letter except in respect of one point to which our article (in our last issue) on the Medical Bill refers. It is necessary for us, however, to say that our statement that diplomas "will, however, be necessary for anyone going for the final examination," was the reverse of what we meant to say, the word "not" having been omitted in error after "however;" the construction of the sentence shows this. We are fully aware that the Bill, though it makes diplomas almost indispensable, does not insist on them; and we are glad that Dr. Kidd has called our attention to this error, though we are altogether at variance with him as to the effect of this part of the Bill.

Dr. Kidd seems to us to interpret the Bill according to his own hostile bias. We try to interpret it according to what we believe is its reasonable meaning and what we know to be the intention of its framers. If it contained all that he conceives it does, he would be quite right to resist it; but, as he is a pronounced advocate of free trade in medical practice, and, *equitur*, in the qualifications necessary for practice, we are not surprised at his opposition to a Bill which aims at limiting the charming freedom of traffic in diplomas which has heretofore existed.—ED.]

Obituary.

DR. J. HUTTON BALFOUR, OF EDINBURGH.

WITH but an interval of three days from the appointment of Dr. J. Bayley Balfour to the professorial Chair of Botany in the University of Oxford, comes the sad news of the death of the father of this gentleman, Dr. John Hutton Balfour, lately Emeritus Professor of Medicine and Botany in the University of Edinburgh. To deceased may be ascribed the distinguished position of having reached the highest step on the ladder of botanical science, and of whom it might with justice be said a few days ago, that he was one of the greatest living authorities on that study which was the aim of his highest ambition, and the study to which he devoted his long life. Dr. Hutton Balfour was a prolific writer, but he never wrote for the sake of writing, nor unless he had something which had hitherto been unsaid. The works and articles from his pen would almost fill a small library, and his labours were rewarded by the bestowal of the Fellowship or Membership of some of the highest scientific societies throughout the civilised world. Beside these foreign distinctions, Dr. Balfour was elected an F.R.S. of both the London and Edinburgh Royal Societies, and received the honorary degree of LL.D. of three of the Scottish Universities. At the time of his death, which occurred on Monday last, at his residence in Edinburgh, he was in the 76th year of his age, and merited the high personal regard which every one who knew him entertained.

PASS LISTS.

Royal Colleges of Physicians and Surgeons, Edinburgh.—Double Qualification.—The following gentlemen passed their first professional examination during the January sittings of the Examiners:—

John Struthers Stewart, Lanarkshire; Chandos William Hoskyns Abrahall, London; George Arthur Herbert Woodforde, London; Emmanuel Portal, Mauritius; Charles Jenkins Lumpkin, Sierra Leone; Ernest Goode, Birmingham; Hugh St. David Griffiths, Cheltenham; Evan Jones, South Wales; Frederic Julian Stone, Glasgow; Hamilton

Edward Leonard Earle, Plymouth; Lionel George Wright, Colomb o, Ceylon; John Arthur, Co. Derry; Henry Joshua Augustine, Calcutta; Robert Michael Forde, Lisnaboy Cottage, Cloyne; Hammoud William Rufus Richardson Crosse, Middlesex; Parvah Nath Datta, Beagal; George Martin Givern, Blackrock, Co. Antrim; James Bernard Wall, Blyth, Coleshill, Birmingham; Godfrey Ernest Garde, Timoleague; Edward Davies, Barmouth; Robert Morrison, Toberdoney; Samuel Wimbush, Heslerton; Thomas James Galloway Ganett, Exeter; John Harford Jones, Merthyr Tydfil; Richard Power Rankin, Victoria, Australia; James Gray, Keith; Henry Peter Huybartz, Ceylon.

The following gentlemen passed their final examination in February, and were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh:—

John Struthers Stewart, Lanarkshire; Charles Edward Morris, Campden; Charles Jenkins Lumpkin, Sierra Leone; Richard Nasson Gaggin, Bally Richard; William Caesar Hamilton, East Lothian; William James McFarland, Co. Tyrone; John William Irvine, San Francisco; Allen Adair Dighton, Gloucestershire; Joseph Bowmer Drew, Stow-on-the-Wold; John Hanson, Weeting, Norfolk; Augustus William Dalby, Jedburgh; Joseph George Garibaldi Corkhill, Liverpool; Archibald Harper, Co. Monaghan; Robert Knox Carleton Graham McCorkill, Canada; Lewis D'Almeida, India; Thomas Adam Beresford Kane, Co. Armagh; Maurice Stack Cussen, Co. Kerry; Charles Horace Barkley, London; Arthur Nathaniel Barnley, Bedfordshire; William Holberton Square, Kingsbridge; Ernest James Flynn, Dublin; Herbert Longmore Grant Chevers, Calcutta; Hamilton Edward Leonard Earle, Plymouth; Oliver Grenville Taaffe, Sherbourne; William Richard Condon, Tipperary; William Frederick Hamilton, Londonderry; Richard Ferdinand O'Farrell, Galway; Ernest Howard Goode, Birmingham; Samuel Oliver Eades, India; Charles Reidy, Limerick; Edward Hodges Goggin Phillips, Limerick; John Henry McAuley, Randsalestown; James Orr, Kilbride; John Joseph Hanly, Co. Tipperary; Simon Vincent Daly, Cork; Alexander James Griffith, Co. Leitrim; John McMichael, Dublin; Donald Alexander MacCrimmon, Ontario; Edward Flood McGrath, Co. Cork; Henry George Thomas, Ceylon; Thomas Francis Hanly, Co. Tipperary; William Gibb, Dundee; Richard Fitzmaurice, Co. Cork; William Robinson, Co. Derry; David Matthewson Nairn, Dundee; Joseph Amy, Jersey; Alexander Willcox McFadyen, Stirling.

Royal College of Surgeons of Edinburgh.—During the January sittings of the Examiners the following gentlemen passed their first professional examination:—

Samuel Garland Sharpe, Norwich; and Louis Edgar Portal, Mauritius. And the following gentlemen passed their final examination and were admitted Licentiates of the College:—

George Lowbridge Baker, Dorchester; Edwin Harold Brown, Bombay; and Henry Edwin Newman Dobie, China. Mr. George Dall Orrock, of Edinburgh, having passed his final examination, was admitted L.D.S. Edinburgh.

Glasgow Faculty of Physicians and Surgeons.—At the last sittings of the Examiners the following gentlemen were admitted Licentiates of the Faculty:—

John William Whyte, London, and James Mason, Glasgow—both of the Glasgow Medical School.

The following have been admitted Licentiates of the Faculty and of the Royal College of Physicians of Edinburgh:—

John Marshall, Cambridge; Robert Price, Glasgow; and Thomas Owen Williams, Glasgow—all of the Glasgow Medical School; James Brown, Biggar, of the Edinburgh Medical School; Albert Edward Hindle, Fairfield, James R. Fletcher, Manchester—both of Owens College; and Thomas Herbert Coskery, Glasgow, of Grant College, Bombay.

Notices to Correspondents.

✍ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE SERVICES OF MIDWIVES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel much obliged if you or some of your readers would kindly answer the following questions: What is the experience of dispensary surgeons as to the value of a qualified midwife? What is the usual mode of obtaining one? What are her required qualifications? What are her duties; and who orders her services to a case? What is her tenure of office? What is her ordinary salary. If sent to the country are her travelling expenses paid?

Yours, &c.,

A DISPENSARY SURGEON.

DR. CULMORE.—Your paper "On the Origin of the late Epidemic of Cholera in Egypt" received, and will be considered.

CONFINEMENT OF LUNATICS (Ireland).—The commitment of a lunatic

on order of one Justice only is illegal and invalid, and should be at once corrected. See Act 1 Vict. cap. 37, quoted in preamble of Dangerous Lunatics (Irish Medical Directory, page 483). No fee can be claimed for medical services under these circumstances. Get the lunatic re-examined by two Justices.—ED.

PARLIAMENTARY TACTICS OF THE ANTI-VACCINATIONISTS.

It is reported that, notwithstanding the overwhelming defeat last session of his anti-vaccination motion, which was rejected by 286 votes to 16, Mr. P. A. Taylor has determined once more to challenge the judgment of the House of Commons on the same topic. This year, however, instead of proceeding by way of motion, he will bring in a bill for the repeal of the compulsory clauses of the Vaccination Acts. Several members—among them Sir Joseph Pease and Mr. J. B. Holland—who are not disposed to support absolute repeal, are prepared, nevertheless, to restrict the infliction of cumulative penalties, and it is understood that the Local Government Board itself is adverse to the repeated prosecution of parents who conscientiously object to vaccination.

MR. J. BROWN (Burnley).—We shall probably draw attention to the subject in our next.

CURE OF CATARACT WITHOUT OPERATION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to Dr. Roche's cases of cataract cured without operation, published in your journal, page 123, I would state that in the "Medical Digest," section 1869, a series of interesting papers, by different observers, are recorded, which are well worth the notice of those whose attention is directed to the subject.

60 Boundary Rd., S. Hampstead,

February 9, 1884.

Yours, &c.

RICHD. NEALE, M.D. Lond.

MR. C. C. DICKSON (Edinburgh).—On reference to Pass List in present issue you will see your request has been attended to.

THE BLIND.

THE last Census reveals the encouraging fact that the proportion of the blind to the population has decreased with each successive enumeration since 1851, in which year account of them was taken for the first time. The decrease in the decade ending in 1881 was much greater than in either of the preceding decennial intervals, the number of cases returned on this latter occasion being 22,32, equal to one blind person in every 1,138. This decrease is fairly attributable to the progressive improvement in the surgical treatment of affections of the eye and to the diminished prevalence among children of small-pox.

ERRATUM.—In the title to Dr. Martin's case, published on Jan. 30, "Liver dyspnea" should be simply "Dyspnea."

THE FIRST LEGAL DECISION UNDER THE DENTAL ACT.

A CASE of considerable importance was decided a few days since at the Stratford Police Court. This being the first, it was looked upon as a test case, and attracted much interest. The defendant, who carried on business as a chemist and dental surgeon at Stratford, Essex, was the holder of a diploma as a licentiate in dental surgery conferred upon him by a colonial body admittedly capable of granting such a degree. This body was the Medical College of Ontario, Canada. The Dental Act, which came into operation in 1878, insisted upon the registration in the Dental Register of all dentists in the country, under various qualifications therein provided. The sixth section provided that any person should be registered who was a licentiate in dental surgery or dentistry, or who was entitled as thereinafter mentioned to be registered as a foreign or colonial dentist; or who was at the passing of the Act bona fide engaged in the practice of dentistry or dental surgery. The defendant applied for registration under the Act, as being the holder of a colonial diploma under the second sub-clause. The General Council refused registration on this qualification, refusing, as they were entitled to do, by section 10, the diploma of the College of Ontario. Upon this refusal it was open to the defendant to appeal against such decision to the Privy Council, but he did not appeal—in fact, accepted their ruling; and thereupon he applied to be registered under the third sub-clause as having been in practice at the passing of the Act, and was so registered, his name appearing in the "Dental Register" with the qualification set forth in the third sub-clause. Recently he was found to advertise himself with the title L.D.S., and the magistrate ruled (we think rightly) that the defendant thereby had committed an offence within the meaning of the Act in using the designation of a qualification which he did not possess. The defendant would have been within his right had he used the letters "L.D.S. Ontario," or simply advertised himself as "Dental Surgeon," but taking into account that it was the first case under the Act, and having regard to the fact that the defendant was an "L.D.S.," though of Ontario, he would not impose the full penalty of £20, but a fine of £2, and the usual court costs.

MR. J. S. BOWNNE (New York).—Communication received with thanks. Letter handed to the gentleman referred to and found satisfactory.

MR. P. E. (Bloomsbury).—The time mentioned will suit admirably. We have entered the appointment.

Meetings of the Societies.

WEDNESDAY, FEBRUARY 13TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Parker, On Mammalian Descent.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 8 p.m., Discussion of Surgeon-General Hunter's paper on The Origin of the Cholera Epidemic of 1833 in Egypt.

ROYAL MICROSCOPICAL SOCIETY.—At 8 p.m., Annual Meeting.

EDINBURGH OBSTETRICAL SOCIETY.—At 8 p.m., Dr. R. Bell, On Displacements of the Uterus and their Treatment by means of Medicated Tampons.—Dr. Angus Macdonald, On Lupus of the Vulvo-anal Region, with Case.—Dr. James Carmichael, On Artificial Lactation of Infants.

THURSDAY, FEBRUARY 14TH.

ACADEMY OF MEDICINE IN IRELAND (Medical Section).—At 8 p.m., Living Specimens: Dr. R. A. Hayes, Two Cases of Emphysema successfully treated by Antiseptic Irrigation. Paper: Dr. C. J. Nixon, Notes of a Case of Primary Lateral Sclerosis (patient exhibited).—A Discussion will take place on the Present Epidemic of Scarlet Fever in Dublin.

ACADEMY OF MEDICINE IN IRELAND (Public Health Sub-Section).—At 8 p.m., Dr. Grimshaw (Chairman), Address.—Dr. H. Colpoys Tweedy, State Control for Chronic Inebriates.—Dr. C. A. Cameroo, Antiseptic Experiments in a Mortuary Vault.

FRIDAY, FEBRUARY 15TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Parker, On Mammalian Descent.

CHARING CROSS HOSPITAL MEDICAL SOCIETY.—At 8 p.m., Mr. C. F. Clarke, On Skin-Diseases in Children.

ROYAL INSTITUTION.—At 8 p.m., Professor Thorpe, On the Chemical Work of Wöhler.

SATURDAY, FEBRUARY 16TH.

ROYAL INSTITUTION.—At 8 p.m., Professor Morley, On Life and Literature under Charles I.

Vacancies.

Armagh Union, Richhill Dispensary.—Medical Officer. Salary, £140.

Election, February 25. (See advt.)

Chorley Dispensary.—House Surgeon and Apothecary. Salary, £130.

Applications to the Secretary before February 20.

Coombe Hospital, Dublin.—Assistant to Master. Applications to

Master, or at Coombe Hospital.

Ely Dispensary.—Surgeon-in-Ordinary and Dispenser. Salary, £30.

Applications to the Hon. Sec. by February 16.

Hospital for Consumption and Diseases of the Chest.—Resident

Clinical Assistant. Applications to the Secretary by February 16.

Jersey General Dispensary.—Medical Officer. Salary, £120, with

apartments. Application to the Hon. Secretary.

Nottingham Borough Asylum.—Assistant Medical Officer. Salary,

£100, with board, &c. Applications to the Medical Superintendent

by February 16.

Royal Free Hospital, London.—Resident Medical Officer. Salary,

£104, with board. Applications to the Secretary before Feb. 17.

(See advt.)

Royal Surrey County Hospital, Guildford.—House Surgeon. Salary,

£75, with board, &c. Applications to the Assistant Secretary by

February 16.

The General Hospital, Birmingham.—Resident Medical Officer.

Salary, £130, with board and residence. Applications to the

House Governor by February 28.

Appointments.

CROOK, J., M.R.C.S., Medical Officer for the Third District of the

Norwich Union.

DILLON, J. T., M.D., M.Ch.Q.U.I., Medical Officer to the Lister

Workhouse.

POWELL, F. W., M.R.C.P. Ed., M.R.C.S., Medical Officer for the Fifth

District of the Davenport Union.

GRIFFITHS, E. E., M.R.C.S., L.R.C.S. Ed., Government Medical Officer

and Vaccinator for Blenney District, New South Wales.

LITTLEJOHN, H. D., M.D. Ed., L.R.C.S. Ed., Consulting Surgeon to the

Royal Dispensary, Edinburgh.

LOANE, J., M.R.C.P. Ed., M.R.C.S., Medical Officer of Health for the

Whitechapel District.

STEVENSON, T., M.D. Lond., F.R.C.P., Public Analyst for the Borough

of Godalming.

Births.

KNOWLING.—February 4, at 5 Lerdon Terrace, Tenby, the wife of

Ernest Knowling, B.A., M.B. of a son.

STEPHEN.—February 7, at Nicosia, Cyprus, the wife of Guy Neville

Stephen, M.R.C.S., Cyprus Medical Service, of a daughter.

WHEELER.—February 5, at Pembroke Garden, London, W., the wife

of John Wheeler, M.D., of a daughter.

Marriages.

ALLAN—BROWNING.—February 7, at St. Stephen's, St. John's Wood,

Francis John Allan, M.D., of Dock St., E., to Ellen Mary, daughter

of the late Thomas Gaul Browning, A.I.C.E.

ROE—DRARDEN.—February 7, at All Saints' Church, Manchester,

Frederic Leyland Roe, M.R.C.S., L.R.C.P., of Eccles, to Alice A.

A., daughter of John Dearden, Esq., of Strathallen, Douglas, Isle

of Man.

Deaths.

GLEN.—January 31, at Brook Street, Hanover Square, Joseph Glen,

late Physician-General of the Boinbay Presidency, aged 87.

HANBURY.—January 26, at Bombay, Fleet-Surgeon Ingham Hanbury.

OGLE.—February 4, at 30 Cavendish Square, London, Elizabeth, the

beloved wife of John W. Ogle, M.D., aged 53.

PRINCE.—February 5, Charles Edward Prince, M.R.C.S., of Buckhurst

Hill, Essex, and of Balaham, Cambridge.

SMITH.—February 2, at Belle Vue Lodge, Richmond, Surrey, James

Smith, M.R.C.S., aged 90.

TRAVIS.—February 4, at his residence, Camden Town, after a long and

painful illness, Henry Travis, M.D., aged 77.

devoted time and energy to perfecting these priceless adjuncts to vision. Normally, everyone past fifty requires glasses, and in addition great numbers are born with defective eyes, which spectacles alone render useful for the purposes of daily life. Donders, Graëfe, Helmholtz, and others have done much to advance knowledge in this direction within recent years, but Young it was who first pointed the way in this great field of practical beneficence to the dimly seeing.

It is highly important that professional men should generally appreciate the truth contained in these statements, and recognise that not only may congenital defects of the kind in question find a full remedy in suitable glasses, but also that improperly-fitting spectacles induce great distress and inability to see aright. In usual cases, discovery and correction by glasses of such refraction disturbances as myopia and hypermetropia is not very difficult; but when complicated by astigmatism, as in very many instances, only those trained to do so by special studies can hope to deal successfully with the case; and in every such emergency the general practitioner's duty is to send his patient where he will be appropriately treated.

Pointing out how frequently the human eye exhibits defects of axial dimension, and thus entailing inconveniences attending long or short sight, the lecturer reflected on the curious fact that the organ thus commonly imperfect is so often adduced as an instance of precision and adaptability of means to ends. In short sight, due to over-length of eyeball, spectacles, though not absolutely necessary, are convenient; in hypermetropia they are urgently called for, both as aids to sight and as preservative agents.

The group of diseases thus described includes from fifty to sixty per cent. of those affections of the eye met with in modern life.

The second group of diseases to be considered is that including affections attended by opacity of the lens, and resulting in formation of cataract. This occurs in healthy individuals in a large majority of instances, and as equally an evidence of senility as are calcareous arterial degeneration, arcus senilis, and certain forms of rheumatic arthritis. It is easily curable by operation, but only the skilled specialist can undertake such operation with the success that attends it in the present time, when extraction alone is the justifiable means to be resorted to, such older methods as solution, couching, &c., being altogether abandoned in modern surgery.

The forms of opacity denominated zonular cataract and pyramidal cataract, though rare of occurrence, and unimportant from the point of view of treatment, yet possess decided interest on account of the manner in which they illustrate morbid processes. Pyramidal cataract affords irrefragable evidence of what has at some time past taken place, but does not give any indication of prophetic value. It is a dense white, more or less conical structure developed exactly in the centre of the lens, beneath its capsule, and it projects forwards into the pupil. Its presence is infallible proof that its possessor was the subject of purulent ophthalmia during infancy, notwithstanding that such cataract may be the sole defect of the eye, and is associated with a cornea of perfect clearness. Regarding the production of the growth, Mr. Hutchinson observed that statements of certainty could not be made, but that we know the lens, at the period of infancy liable to purulent ophthalmia, is very convex, the anterior chamber being very shallow, and the posterior part of the cornea and the anterior part of the capsule nearly in contact. It is thus conceivable that severe and continued inflammation on the surface of the eye, attended with swelling of the lid, and great increase of heat to the part, might possibly influence the irritation of growing cell structures not themselves directly involved.

Similarly zonular or lamellar cataract is a retrospective symptom, having definite association with disease in infancy, and being not easy to explain. The lens

opacity exists in concentric layers; its nucleus and periphery may be quite clear, and vision be fairly good in its presence; and on dilating the pupil with atropine, diagnosis of the condition as only partially affecting the lens is a simple matter. This form, like pyramidal cataract, is a non-progressive variety, and the disease it points to as having existed in childhood is convulsions, the severity of which, and the duration of the intervals of freedom from them, can be ascertained from observance of the precise position and number of the lamellae of the cataract. Moreover, there is associated with this condition a curiously defective formation of the teeth, concerning which Mr. Hutchinson thus expressed himself:—"Although it is very infrequent to meet with lamellar cataract with sound teeth, yet I believe that the association between the two is not direct. The defect in the teeth is caused by the remedy given for the cure of the convulsions—namely, mercury. If mercury be wholly omitted, then, as I have proved in several instances, the teeth will probably remain sound. Precisely the same conditions of teeth are met with in many persons who have no lamellar cataract, but who, for some reason or other have taken mercury in infancy. Any influence which, in infancy, induces stomatitis, and causes congestion and swelling of the gums, may produce the defects in the teeth to which I now refer. Of these influences mercury is the most potent, and the commonest. We may suitably recognise these teeth as stomatitis teeth. They are most carefully to be distinguished from those which indicate inherited syphilis.

"This discrimination is somewhat difficult, and much confusion has arisen from the fact that the two conditions are very frequently coincident. Syphilitic infants are often—indeed, usually—treated by mercury, and their teeth then show the concomitant results of the taint which they inherited and of the drug which was used for its cure. Yet the distinction between the two kinds of teeth, even when they are met with in the same mouth, is by no means difficult.

"The condition which characterises a syphilitic tooth is a defect in the development of its cusps. That which characterises a stomatitis tooth is a defect in the formation of its enamel. In the one case the tooth is altered in its form; in the other it is pitted, eroded, and discoloured. In both instances it is the permanent set of teeth which shows the damage. The test teeth for syphilis are the upper central incisors; those for stomatitis are the first permanent molars in both jaws. The condition of the test incisors in syphilis is that they are narrow and small and show a single central notch, often, almost usually, without any defect or deficiency of the enamel. The condition shown by the first permanent molar which reveals infantile stomatitis is absence of enamel on the surface of its crown. Other teeth which undergo calcification at about the same period, the incisors and canines, for instance, usually suffer also; whilst those which are calcified much later, the bicuspid, to wit, almost invariably escape."

Respecting the hypothesis of a developmental correlation between the condition of the teeth thus described and lamellar cataract, Mr. Hutchinson, therefore, declares that he is not in agreement with it.

The third group of eye diseases to which the lecturer called attention comprises those of a syphilitic nature, and may, he said, be subdivided into acquired and inherited forms. They include iritis, choroiditis, and retinitis.

Iritis usually develops within a few months from the period at which primary symptoms of syphilis become apparent, and for its treatment free employment of mercury is indicated, and at the onset steps must be taken to promote wide dilatation of the pupil. When the disease is combated at once, and efficiently, it is to be anticipated that no serious consequences will supervene on the condition; but under other circumstances syphilitic inflammation of the choroid may take

place. The formation of small gummata sets in a year or two after the primary symptoms in these cases.

Retinitis makes its appearance at an earlier period than does choroiditis, and it occurs in the subjects of locomotor ataxy attributable to syphilitic infection. The characters of the disease present differences accordingly as it results from acquisition or inheritance of the inducing cause. In the latter class of patients it undoubtedly does occur, though very rarely, and in them it assumes a very severe type, the secondary stage being the period of its development. Another eye affection common among subjects of hereditary syphilis, and all but unknown in those who have acquired the disease, is inflammation of the cornea, the appearance of which may be delayed even for thirty years; but why so extended a period of latency should be exhibited is difficult to explain. Probably the reason may be found in conditions in the cornea itself, and which suffice to determine at what stage of growth the manifestation of the change shall be made. It is not in any way to be associated with a secondary outbreak of virulence on the part of syphilitic poison in the system. For a long time it was classed among strumous affections, owing to the imperfect manner in which its ætiology had been understood; but at the present time it obtains universal recognition under the title of interstitial keratitis, and it is accepted as an absolute indication that the person in whom it is found is the subject of syphilis in the inherited form. Notwithstanding that he has long been on the alert to find an instance of the affection in a person who has not inherited, but has acquired the syphilitic taint, Mr. Hutchinson declared that he had never yet discovered such a case, although in one single instance there was a doubt whether a patient, whose cornea were seats of interstitial keratitis, was or was not to be ranked as an example.

Another group of eye diseases may be classified as being those of a strumous kind, or scrofulous inflammation of the organ; and although particular forms of ophthalmia are no longer recognised as typically scrofulous, still it becomes necessary to remember that there is a certain class of surface affections of the eye the causation of which is found in the scrofulous diathesis. In many cases of this kind the ulceration which sets in, and which is of a phlyctenular variety, will make its appearance in children in close agreement as to manner and time with the conditions observed in the parents previously affected by the disease. Usually commencing in the lids, it spreads from them, and produces intolerance of light, necessitating careful provision against the irritation so induced.

Another group may be made to comprehend certain rare but important diseases of the eye appearing in persons of special diathesis, associated with presence of chilblains on the extremities, and characterised by sluggish circulation, and a peculiar irritability of tissues which exposes them to peculiar liability of injury. In such patients there is apt to be produced a remarkable inflammation of the ciliary region, extending from it, on one hand into the cornea, and on the other into the iris. This, which is not a syphilitic manifestation in the majority of cases, is termed *kerato-cyclo-iritis*. The condition is not curable permanently, constant relapses taking place, the patient in whom it occurs being throughout life liable to attacks of the disease, the reason for which state of things being of course to be sought in the special idiosyncrasies of structure to which in the first instance it is attributable.

Gout and Rheumatism are associated with eye affections which are not very well understood as yet. Notwithstanding the two diseases themselves are distinct from one another, yet they are not unfrequently intermixed, and this leads to confusion in respect to the eye complications which attend upon their course;

but little can be said in this connection except that associated with gouty disease the surface of the eye may become the site of a deposit of urate of soda.

In the case of rheumatism, however, the matter is otherwise, at least fifty per cent. of iritis being encountered in patients with a rheumatic taint. Such *arthritic* iritis run a very different course to that pursued by the syphilitic variety of the same affection, a fact of the utmost importance, and opposed, too, to general belief. Thus the rheumatic iritis is more painful than the syphilitic, is less prone to be associated with effusion of lymph nodules, &c., and above all is distinguished from it by the remarkable tendency it exhibits to relapse. Recurrent attacks of iritis are likewise liable to take place in persons of gouty arthritic diathesis who are subjects of gonorrhœal rheumatism.

The *sclerotic* is very rarely the seat of disease, but it may be so affected.

The question of *emergencies* in eye practice constitutes, Mr. Hutchinson explained, one of the most important subjects with which the general practitioner can have to deal. He must be prepared to decide without delay whether in a particular case the affection he is called to treat demands immediate attention or whether delay in its treatment can be safely ventured, whether, that is, the disease is an acute or a chronic one. In some instances nothing short of immediate action will suffice to preserve the eye, which must infallibly be lost through hesitation or error to diagnose its true condition: such diseases as iritis and muco-purulent ophthalmia may be instanced; and as regards the former it may be laid down as a general rule that on its discovery the use of atropia should always be forthwith adopted. In all forms of purulent ophthalmia the treatment should be, immediate and thorough cleansing of the eye, and application of a solution of zinc chloride, two grains to the ounce of water.

Glaucoma is another condition of emergency demanding recognition, which will be aided by the presence of pain and diminished vision; but it often happens that existence of vomiting and the prostration of the patient deflect attention from the local urgent affection to the constitutional condition, the severity of general symptoms frequently masking the glaucoma until, complete blindness being established, it can no longer escape notice. Early operation in such cases would have prevented the serious condition thus induced.

A Course of Lectures

ON

THE EYE: ITS DISEASES, AND THEIR REMEDIES.

Being an Abstract of a Course of Lectures delivered in the Royal College of Surgeons in Ireland,

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
Professor of Ophthalmic and Aural Surgery in the College;
Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 113.)

Treatment of Granular Conjunctiva.—The cure of the early stages of this disease depends almost as much upon the improvement of the hygienic and constitutional condition of the patient as upon the local treatment. The attack of catarrhal conjunctivitis with which the disease commences is almost always the accompaniment of overcrowding, foul air, and dirty habits, all which conditions are aggravated by the unwillingness of the patient to face the fresh air and light when the smarting lachrymation and intolerance of light are troublesome. It is not too much to say that, if the granular ophthalmia could be seen in its initial stage, and if the patient would consent to take fresh

air and moderate light, and to keep the eyes clean, and refrain from rubbing with a dirty handkerchief, no such disease as chronic granulation would exist. Isolation of granulation patients is strongly insisted upon by most writers on the hypothesis that the conjunctival discharges in the diseases are actually contagious, but I do not attach great importance to this precaution having seen hundreds of cases treated in wards with other patients without any spreading of the disease so long as the wards were well ventilated and not over-crowded, and the patient made to spend most of his day in the open air. In the army and in large public institutions the disease very often spreads rapidly, not, as I think, for want of isolation, but because the moment the initial conjunctivitis is observed the patient is ordered off duty and into the infirmary and kept there inhaling the exhalations of a crowd of other sufferers usually with the light excluded, the windows closed, and upon low diet.

Open air, personal exercise, cleanliness, and a nutritious and digestible dietary are indispensable means of combating granular ophthalmia. The exposure of the eye to a moderate light is also, in my opinion, an important factor in the treatment, and I altogether deprecate the use of bandages, compresses, green shades, or blue spectacles, except in cases in which the photophobia is sufficient to make it impossible for the patient to open the eye. The patient should sleep under light bed clothing, without bed curtains, and with the window and window shutters partly open; the room should have as few other occupants as possible, and the patient should not remain in bed a moment longer or go to bed a moment sooner than the other members of the family. Having thoroughly cleaned the eyes with an antiseptic wash of diluted carbolic acid or permanganate of potash, he should breakfast on light nutritious material; milk, porridge, eggs, and fish are suitable. After breakfast he should walk out for an hour or two, taking the shady side of the road, and, if necessary, using a parasol, but, if possible, no green shade, and refraining from keeping the hand or handkerchief to the eye, and the same course should be adopted throughout the day returning home for meals and rest. When at home he should sit with back to light, not over the fire, or in flaring gas light, and should not retire to bed earlier than if he were in health. These hygienic precautions are, in the case of children excessively troublesome and the line of treatment is not popular with mothers, who find it much more convenient to leave the child in bed than to send it out, or keep it amused when out of bed, but they are, nevertheless, quite essential, and perseverance in them for two or three days will, in many cases, put the patient in a fair way toward convalescence. The improvement in constitutional condition may be greatly assisted by a tonic line of treatment, the nature of which I have indicated when writing of phlyctenular ophthalmia.

The local treatment of granulation consists in the direct application to them of astringents and escharotics with greater or less freedom. The slight degree of hypertrophy of the papillæ which arises from the accommodative hyperæmia of the conjunctiva already spoken of, can readily be relieved, when the error of accommodation is corrected, by washing the everted lid with a ten grain solution of silver nitrate.

The "sago grain," or "vesicular" granulations are not difficult of cure. They may occasionally be picked out of the everted lid surface with a needle point, but pricking them for the purpose of allowing the escape of contents is useless. The seat of the granulation should be washed with a strong astringent. The saturated solution of acetate of lead, or 15 grain solution of silver nitrate are not too strong, and if the "sago grains" are fully developed a touch of sulphate of copper, or even of a mitigated nitrate of silver point, will be necessary, and in the intervals of such treatment the patient may advantageously use the tannic acid collyrium already prescribed.

The second form of granulation, *i.e.*, the papillary

hypertrophy, needs much more decisive treatment. When it is in the highly vascular swollen condition the conjunctiva of both lids should be habitually washed with a 30 grain silver nitrate solution, and if it has reached the stage of cauliflower growths it may be necessary to shave them off, and, when the bleeding has ceased, apply lightly the solid caustic over the whole surface. The solid sulphate of copper, though somewhat unfashionable at present, is unquestionably the safest and best conjunctival astringent for general use. It is much more effective than powdered acetate of lead, and more lasting in its effects and not open to the danger of a deposit of lead chloride in a corneal ulcer if one should exist. It can hardly do mischief by injuring the cornea as sulphate of zinc, liquor potassæ, and solid nitrate of silver may do, and it is always ready to hand, never suffering decomposition by exposure or use. The eye douche is comforting to the patient and unobjectionable, but it is useless as a means of treatment.

The third, or neoplastic, hard, pale, warty form of granulation will not yield to anything but the strongest escharotics, such as the solid nitrate of silver, and when reduced to a smooth surface they generally leave the lid conjunctiva atrophied, cicatrised, and more or less dry. There is no treatment of them which obviates the risk of this result because they involve the whole substance of the conjunctiva and sub-conjunctival tissue. The solid stick of nitrate of silver, or of the same mitigated by the addition of potash nitrate, is the best escharotic for these cases, but when this is used it should not be forgotten to wash the lid off well with a solution of sodic chloride, lest a spicula of unneutralised nitrate may remain, and, when turned in on the eyeball, cause an ulcer. In the use of escharotics to the conjunctiva care must be taken not to be too free with the application or burn too deep, or the whole thickness of the membrane may be destroyed and a cicatricial surface left which is quite sufficient to keep up irritation for the rest of the patient's life. This cicatricial condition, resulting sometimes from disease and occasionally from injudicious use of escharotics, is the most usual cause of lid inversion.

THE CORNEA AND ITS DISEASES.

Its Anatomy. The Cornea is the lenticular window placed in the front of the eye to admit rays of light and to help to concentrate those rays to a point on the retina. It is nearly circular, and is a thick transparent membrane composed of a large number of concentric layers bounded before and behind by homogeneous elastic laminae, which are each covered by a coat of epithelium. The cornea forms about one-sixth of the ocular globe, its diameter being 0.48 of an inch, and it presents a convex surface anteriorly of a slightly paraboloid curve, and a concave surface posteriorly of spherical curve. It is slightly thinner in the centre (.04 of an inch) than at the edges, and its curvatures are, in health, perfectly symmetrical, so that the focal length of every one of its meridians are exactly equal. A fault in this symmetrical accuracy of meridional curvature produces an optical error of the eye known as astigmatism.

The Cornea therefore consists of

- a. The Cornea proper or laminated structure, bounded anteriorly by
- b. The anterior elastic lamina or Bowman's layer, a hyaline structureless stratum, which is covered anteriorly by
- c. The epithelial layer, continued from the conjunctival surface. Posteriorly the cornea is proper bounded by
- d. The posterior lamina, or membrane of Demours or Descemet of nearly similar structure to Bowman's layer, and it, in turn, is covered by
- e. A very fine layer of epithelium.

The cornea is fitted into the opening in the sclerotic and is continuous with the sclerotic, being slightly

overlapped by that structure as a glass is fitted into a watch case. The epithelium on its anterior surface is columnar in its lower stratum, where it rests on Bowman's layer, and at the surface it presents an aggregation of polygonal cells which send down projections between the subjacent columns.

The anterior elastic lamina of Bowman is a thin stratum about 1-1200th of an inch in thickness; it is homogeneous and structureless, and contains no cells or corpuscles, but it does not otherwise differ from the corneal structure. It is connected with the subjacent cornea by fibres which pass obliquely from one to the other, and is extremely tough and elastic, characteristics which are manifested by the force with which it holds a foreign body which has become impacted, and which it is often found necessary to dig out of this retentive layer.

The cornea proper or substantia propria, is a modification of connective tissue, and formed of about 60 concentric laminae, which, however, are so equally transparent that the demarcation between them is hardly distinguishable under the microscope until they have been prepared for examination with reagents. The fibres in these laminae

Fig. 16.—Section through Cornea and Conjunctiva.

run parallel to each other and to the surfaces of the cornea, but each laminae is connected with its neighbour by interlacing fibres. The fibres are collected into small bundles, and in the spaces between these bundles are the cell spaces which contain the corneal corpuscles. These cell spaces are irregularly stellate chambers flattened by the superimposed laminae, and their rays communicate freely with each other, both those in the same lamina, and occasionally those above and below. The net work formed by these cell spaces and their offsets receives the name of Recklinghausen's canals. In these cell spaces lie the corneal corpuscles, fitting the space, but somewhat smaller, so that room is left for the circulation of the lymph in which they lie. These corpuscles are composed of protoplasm, and they communicate with each other by minute fibrils sent through the anastomosing rays of the cell spaces.

At its margin the cornea is continuous with the sclerotic coat, its fibres merging in the scleral fibres, and the cell spaces being lost in the latter.

The posterior elastic lamina or membrane of Descemet or Demours (two French physiologists who simultaneously described it) is of similar structureless character to the anterior lamina, but is thinner, and less firmly attached to the cornea. It is highly elastic, and when detached curls up, and it resists inflammatory conditions and chemical reagents in a remarkable manner. It contains no cells or corpuscles, nor any visible fibres, but at its margin it splits up into bundles, some of which pass into the iris and choroid margin, and receive the name of the "pillars" of the iris, while other bundles join the corneal edge and the sclerotic. The dentated edge of the posterior lamina thus formed is called the *ligamentum*

pectinatum. The spaces between these bundles of the fibres of the posterior lamina are open to the aqueous chamber, and are called the *spaces of Fontana*, or *cavernous spaces*. In the immediate neighbourhood of these spaces, but in the substance of the sclerotic, is another and much larger elliptical space called the *canal of Schlemm* or circular sinus of the iris. This cavity is lined with epithelium, and with it some of the anterior veins of the sclerotic communicate, and between this canal and the spaces of Fontana there is a close connection, if not an actual communication, by which means the sclerotic venous system is brought almost into intimate communication with the aqueous chamber.

The posterior epithelial layer consists of a single row of cells of such delicacy as to be barely distinguishable, they cover the back of the entire cornea, and are reflected to the surface of the iris, the whole of which is also invested with them.

Blood Supply.—The cornea is a non-vascular substance, and no blood vessels are to be found in it when in the healthy state, excepting that the conjunctival and scleral capillaries form loops around the margin. In the disease called pannus, however, the surface of the structure becomes highly vascular.

The nerve supply is, on the contrary, very abundant, from which arises the extreme irritability of corneal ulcers, and the great intolerance of light which arises from the reflection of the nerve irritation from the ulcer to the retina. The supply is derived from the long ciliary branches of the fifth nerve, which enter the sclerotic close to the corneal edge, and are continued on to the number of about forty to form three consecutive plexuses. The first of these is situated within the corneal surface, and is called the primary or fundamental plexus. From this two sets of fibres are derived, one set of which pass between the laminae and are lost in a network of ultimate fibrils; the second set consists of a number of much finer nerves which pass through the anterior elastic lamina converging towards the centre of the cornea, and they form another minute plexus on its surface, and under the epithelial coat, being known as the secondary or sub-epithelial plexus. From this a further ramification of very minute twigs pass into, and are distributed amongst the epithelial cells, ending there in little terminal knobs. This aggregation of ultimate nervelets gets the name of *intra-epithelial plexus*.

The intra-corneal ultimate fibrils pass freely through the canals of Recklinghausen, or anastomosing branches of the corneal cells, and are there in close proximity, if not in actual connection with the corpuscles. No lymphatics are found in the cornea.

(To be continued.)

CLINICAL MEMORANDA.—NOTE ON NITRATE OF SILVER IN THE TREATMENT OF CONJUNCTIVITIS, SIMPLE AND PURULENT.

By JOHN W. MARTIN, M.D.,
Sheffield.

DURING the progress of Dr. Jacob's "Lectures on Eye Diseases" through the columns of the *Medical Press*, I wish briefly to record the uniform success that has attended the hourly instillation of a solution of nitrate of silver, strength gr. j. to the ʒj. of water, in cases that have come under my care. Whenever there is any tendency to congestion of the conjunctival vessels, and pain and tenderness of the eye, I know no treatment more likely to give relief, and to effect a cure. Its application is almost, if not altogether, harmless, and the good effects are at once felt. In the purulent ophthalmia of the neonatorum I have found it wonderfully efficient in putting an end to the disease. Patients to whom I have given this solution carefully preserve the bottle, and give it to their friends, and always report upon its good effects, saying, that "it is worth its weight in gold," in spite of my warnings that they ought not so to use it, unless under proper direction.

The treatment certainly bears a most favourable comparison with other methods. It is pleasanter than the use of zinc and other washes, which are applied by bathing the eye, and which rarely get through the closed lids; and it appears to me to be much less painful, and far more efficacious, than the use of the stronger solutions, such as gr. v. of nitrate of silver to the 3j. of water. In such cases, its prescription has become almost a matter of routine practice, so universally successful have been the results obtained.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Case of Pneumonia in a Child.

Under the care of REGINALD SOUTHEY, M.D.
Oxon., F.R.C.P. Lond.

(We are indebted to Mr. ALBERT GRESSWELL, B.A.
Oxon., M.R.C.S., for this report.)

MARY ANN G., æt. six, a school girl, was admitted to Faith Ward, November 3rd, 1882, suffering from pneumonia in an early stage. She was a fair complexioned, well-nourished child. On admission, she was wandering, restless, chilly, and very thirsty. Her face was flushed, her skin, lips, and tongue were dry, and she lay on her right side. The throat was natural, the cervical glands not enlarged, the pupils were natural, and freely reacted, there was no squint, and there was some injection of the right conjunctiva. There was twitching now and then of the muscles of mastication and of the muscles of the arms. Air entered freely into the lungs, before and behind, the resonance was good all over the lungs, the heart's impulse was forcible, the apex beating in the fourth space and nipple line (the normal situation in a child of her age), the sounds clear, the abdomen prominent, its walls firm. The extremities were natural.

The mother gave the following history of the child:—She was quite well on the 2nd inst. at 9 a.m., when she partook of a hearty breakfast, and then went to school. At noon, however, she cried and complained greatly of a dreadful frontal headache. At 1 p.m. she was very light-headed. At 4 p.m. an aperient (of rhubarb, &c.) was given to her, and the bowels were freely open, but they have not been open since. She was very sick, rejecting all the milk she took, and during the night she was very delirious, and was convulsed in all her limbs. This morning she was taken to King's College Hospital and then brought here and admitted.

To day, the 3rd, she has not been sick, and the bowels have not been open. She has taken freely of milk, indeed, she has been very thirsty. Her pulse is 120 and feeble. Respiration 24 and very regular. Temperature 103. Urine has a specific gravity of 1020, is dark amber coloured, acid, clear, and contains no albumen. In the evening pulse 132, respiration 42.

Ordered D. L. Balneum tepidum. Hst. soda tartratis effv., ʒss. ter die, and an enema of milk and water.

The following daily notes record her progress:—

Nov. 4th—Was convulsed four times during the night (in the arms and mouth), and was given three warm baths. Each convulsion lasted about three minutes, and quickly abated on immersing the child in warm water. She screamed a good deal during the night, was very thirsty, drinking milk freely. Bowels not open. Urine passed under her. Pupils react, equal and circular. Each ocular conjunctiva is injected. No retraction of abdomen, pulse 132, respirations 42. No abnormal physical signs in the lungs. Temperature 103.8.

5th—Had no more convulsions after those of the night of the 3rd inst. Is more rational this morning, asking for milk and putting out her tongue when asked to do so. She however, still talks a good deal to herself, and still is crouched on one or the other side, and the head is held in a state of cervical opisthotonos, somewhat rigidly. The tongue is not so dry, presenting on the dorsum a thick white fur studded with prominent red papillæ, the tip and edges being moist. Pulse 120 very small and weak. Respirations 58.

Bowels open once rather loosely yesterday. Temperature 103.4.

P.M.—She now recognises her mother, and talks rationally at times, but those periods are not of long duration, being quickly followed by semi-delirious states, when she mutters to herself, and at times repeats the numbers 1, 2, 3, 4, 5, 6, &c. Slight impairment of resonance over the right infraclavicular region. Ordered D. L. Beef tea. Tinct. opii, m.v., to be added to the draught, also cataplasma lini to the right side every third hour.

6th—Slept after tinct. opii, m.x. Bowels open last afternoon, very light motion and slightly formed. Takes milk very freely, always asks for milk, and drinks five or six pints in twenty-four hours. No vomiting. No convulsions. Tongue cleaning. Some white patches left on tongue at the back of the dorsum, the rest of the tongue is clear and moist. Puts out her tongue when asked to do so, and seems to be much more rational, answering questions correctly. Blush on each cheek. Pulse 120, smaller and weaker. Respirations 58. Bronchial breathing, bronchophony, and dullness over the right supra-scapular region. Compensative breathing elsewhere. Temperature 103.2.

7th—Quite sensible. Skin is still very hot and slightly perspiring in the palms. Coughs a little. Pulse 108. Respirations 48, very shallow. Tongue moister and cleaner. Bronchial breathing and dullness well marked over the right supra-clavicular and infra-clavicular regions. Loud compensative breathing elsewhere.

8th—Coughs much more, and the cough is much looser. Reduc crepitation at the right apex in front. Bronchial breathing and bronchophony well heard in front and behind over the right apex. Talks very well. Somewhat more drowsy than she was. Tongue cleaner. Water passed very freely. Ordered wine ʒiv., brandy ʒij.,

Hst. ammon, acetatis c camph. ʒss.;

Tinct. camph. C., m.x.;

Sp. ammon arom, m.x. 4trs. horis.

9th—Very restless night, sleeping but little. Very thirsty. Passes water freely. Tongue moist and clean. Temperature 103.6. Bowels open last afternoon. Coughs a little and more loosely. Bronchial quality of breathing sound at apex of the right side is being lost, the crepitations masking it perhaps. Ordered 1 egg.

10th—Temperature fell by crisis last night to 97.6. Lies comfortably asleep breathing much more quietly. Respirations 28. Pulse 72, stronger. Is very thirsty. Bowels not open. Many fine crepitations at the right apex. Ordered, brandy ʒij. and custard pudding.

11th—Good night. Not so thirsty. Passes water freely. Tongue cleaner, slight white fur at the root. Coughs much more, and much more loosely. Bowels open twice freely during last twenty-four hours. Crepitations still at apex. Temperature 96.

12th—Very good night. Coughs a little. Talks well. Bowels not open.

13th—Very good night. Talks very well. Bowels open yesterday freely. Ordered D. L. Wine ʒij., beef-tea, eggs 2, custard pudding.

14th—Very good night. Bowels open freely yesterday. Talks well. No cough. No vomiting. No pain. Little rhonchus occasionally at right base, and over right scapula and interscapular region. Air seems to enter freely into right supra-scapular region, without any moist sounds there.

15th—Good night. Bowels open freely yesterday. Talks very well.

16th—Good night. Bowels open freely yesterday. Talks very well. Ordered D. D. Milk pudding and 2 eggs.

17th—Good night. Talks very well. Bowels open yesterday. Tongue clean and moist. Lungs quite healthy.

18th—Doing well. Been up three days. Tongue moist and pale.

23rd—Good nights. Talks very well. Bowels open.

27th—Doing very well.

December 1st—Discharged.

A SO-CALLED epidemic of cholera is said to have broken out in a girls' school at Moscow, and to have manifested itself simultaneously in eighteen different houses in which the school-girls reside.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

A MEETING of the Medical Section was held in the College of Physicians on Friday evening, Jan. 18, Dr. WM. MOORE, President, in the chair.

Dr. A. N. MONTGOMERY, Hon. Sec., read the minutes of the previous meeting, which were confirmed.

LIVING SPECIMEN.

Mr. ARTHUR H. BENSON.—Case of *tubercles dorsalis*, showing "Argyle Robertson's sign" well marked and atrophy of optic nerves.

SPECIMENS BY CARD.

Dr. WALTER G. SMITH.—Drawings: 1. Multiple onychia; and 2. Peculiar condition of skin of scrotum.

Dr. J. HAWTREY BENSON.—Primary, malignant disease of the liver.

BRONCHITIS AND EMPHYSEMA WITH REMARKABLE SYMPTOMS.

Dr. H. V. DILLON read a paper on a case of bronchitis and emphysema, loss of taste and partial loss of deglutition subsequent to injury of upper cervical vertebrae. The facts were these: D. S., a pensioner, *æt.* 38. Health always good till injury was received. Served seventeen years in the British army, during which time he suffered from dysentery and *gñe*. Had had gonorrhoea, but no specific disease. On Jan. 17, 1881, as he was sitting in the fore-castle of a ship, a sailor fell from the yard-arm on to the back of D. S.'s head, bending it and his neck forwards. D. S. felt at the time as if something had given way at the back of his neck. He heard a noise at the seat of injury, and then became unconscious, remaining so for about 15 minutes. On coming to he felt excruciating pain at the seat of injury, which lasted for six months, and radiated along the back of the head. At the expiration of this time a hardened enlargement was remarked at the back of the neck over the three upper cervical vertebrae in the mesial line. A few months subsequently he got an abscess of the left internal ear, which discharged externally from July, 1881, to July, 1883. The auditory canal became almost completely closed, and hearing was lost at that side. Subsequently cough and dyspnoea came on, and lasted since. The lungs are emphysematous, and he suffers from bronchitis, huskiness of the voice, impaired power of deglutition, and partial loss of taste. Five months after the left ear distress ulceration took place in the upper gums, the teeth loosened, and later on there was necrosis of the alveolar process of the superior maxilla, portion of the bone coming away when the teeth were extracted. The hard palate then ulcerated. The respiration is of a harsh and blowing character, pointing to paralysis of the soft palate. About six or eight months ago there was a circumscribed patch of congestion at the base of the left lung which disappeared on treatment. He had lost flesh considerably since the accident, but had no signs of paralysis. The swelling at the seat of injury was now confined to the right side, having disappeared from the median line within the past year. He could not rotate the head completely to either side; neither could he flex or extend it to the full extent.

Dr. HENRY KENNEDY asked if there was any evidence of abscess about the nape of the neck.

Mr. WM. STOKES having seen the case, said it was one of extreme rarity. The view one suggested that it was a case of cervical dislocation could not be maintained, having regard to the complete absence of symptoms of motor paralysis. He considered the injury resulted in osteitis and periosteitis of the upper cervical vertebrae; that this process extended upwards, involving the temporal bone, and subsequently the superior maxilla on the left side, and that this was followed by caries. He asked, was there any trace of a syphilitic taint?

The PRESIDENT considered the case one of great interest.

Dr. DILLON, in reply, denied the existence of any abscess in the neck or of any syphilitic taint in the patient, and considered that the symptoms might be referred to stretching of the *atlo-axoid* ligaments and consequent inflammation.

CASE OF PNEUMONIA WITH PARADOXICAL TEMPERATURES.

Dr. C. F. KNIGHT reported a case of pneumonia with frequent paradoxical temperature in a woman, *æt.* 30, and in whom large doses of quinine were administered.

Dr. CAMERON had frequently tested the temperature of the

patient when in the Adelaide Hospital, but never found it above 99°. He suggested the possibility of the absence of toxic symptoms after the large doses of quinine being due to its being mixed with cinchonine.

Dr. WOODHOUSE stated that the patient had been in the Hardwicke Hospital last June for an attack of typhoid fever. The temperature at the usual time of convalescence, instead of coming down, went up to 104°, 107°, reaching 114° at the end of August, and 127° at the end of September, when a watch being set, she was detected using a piece of lint 12 in. square, which she acknowledged she had employed for the purpose of raising the register of the thermometer by wringing it out of hot water and secreting it under her pillow.

Dr. COX argued that the presence of a cloud in the urine on the application of the picric test was due to the presence of quinine.

Dr. W. G. SMITH pointed out that the presence of any alkaloid would cause a cloud on the addition of picric acid.

Mr. KEENAN and Dr. GUNN doubted whether the patient had taken the large dose of quinine prescribed, and concurred with other speakers that the case was one of malingering.

The PRESIDENT and Mr. ORMSBY having also joined in the discussion,

Dr. KNIGHT replied, and concurred in the view that the case was one of malingering. The picric acid test was applied before a grain of quinine was administered.

POISONING BY THE INGESTION OF TAINTED MEAT.

Dr. J. HAWTREY BENSON read a case of poisoning by the ingestion of tainted meat. The patient had eaten about an ounce of roast turkey which was somewhat high. Immediately afterwards he felt nausea, fetid eructations, &c.; but the symptoms did not meet their maximum severity till about twenty-six hours after. At that time he was extremely faint, pulse 92°, intermittent, scarcely perceptible, extremely compressible; first sound of heart very weak; second sound quite audible, even at base; precordial anxiety and feeling of pressure akin to pain at heart; pupils dilated; vision dim; headache severe. The skin was cold but dry; throat dry and sore; articulation very difficult; tympany great; severe abdominal pain; tenderness along descending colon; constipation. Four hours afterwards his pulse was 104; temperature 101.8°. During the succeeding night he suffered intense fever symptoms, with very marked dryness of skin and mucous membranes. Towards morning he had two very copious watery scalding evacuations, followed by prompt and great relief to all symptoms. During the night he passed a large quantity of urine of specific gravity 1038, containing, in 1,000 cubic centimetres, 34 grammes of urea and 1.39 grammes of uric acid; no sugar; a trace of albumen. Next morning the patient was convalescent, and some days afterwards exhibited a subnormal temperature. The writer then discussed the question whether the case was one of "septic poisoning" or of "septic infection" caused by the entrance into the blood and by the multiplication therein of a specific micro-organism. He referred to the cases described by Van den Corput; and to the Welbeck, and the Nottingham cases examined by Dr. Klein, and to the Wexford cases, investigated and published by Dr. Charles A. Cameron, and expressed an opinion that the symptoms in the case he had just described were produced by the cadaveric alkaloids, his chief reason for this opinion being the rapidity with which the acute symptoms disappeared after copious evacuation, the dilatation of the pupils, the extreme lowering of arterial tension, the dryness of the mucous membranes, and the very rapid convalescence.

Dr. CAMERON said that, as he was himself the patient referred to, he had painful remembrances of the circumstances of the case. He never felt so near dying. He had cold sweat, and felt utterly prostrate, and had great difficulty in walking. He suffered intensely during the two nights. During the first he did not sleep at all, and only obtained about an hour's rest on the second night. He had intense thirst, and suffered great pain. His urine immediately on being passed became quite thick. His mind was quite clear, but he found it difficult to articulate his ideas.

Dr. H. KENNEDY thought that at the time the patient took the tainted meat he was so mentally depressed, and being inclined to gout, he was unfavourable to resisting any disease. With reference to the absence of the second sound of the heart, he had frequently remarked this to be the case in the last cholera epidemic.

Dr. FINNY thought Dr. Kennedy's remarks as to the absence of the second sound of the heart proved the converse of his

proposition; because, while cholera was preceded by evacuation from the intestinal canal, in this patient there was no loss of the usual fluid circulating in his body. He could not understand any reason for the absence of the second sound in this case.

Dr. COX asked where simple indigestion ceased and poisoning began, as he himself had frequently suffered almost as much after taking different kinds of food, which disagreed with him as in the case of the patient under discussion.

Dr. LENTAIGNE mentioned a case where effects similar to those described had been produced by the ingestion of imperfectly boiled Brussels sprouts causing irritation of the intestinal canal. The objectionable matter having been passed, the patient quickly recovered.

Mr. F. A. NIXON: The theory advanced by the last two speakers is opposed by the fact that other members of the family who had partaken of the turkey suffered also.

The PRESIDENT and Dr. DILLON, J. E. KENNY, and W. A. CARTE having joined in the discussion,

Dr. BENSON replied. He said there was no second sound to be heard over the aortic valves, due, he considered, to the extreme lowering of the arterial tension preventing the flapping back of the valves from being heard. He could not undertake to say when indigestion ceased and poisoning began. Anyone seeing his patient during his illness could have had no doubt that his was not a case of indigestion. The fact of other members of the same family being affected confirmed this view.

The Section then adjourned.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

The quarterly meeting of this Association was held at Bethlem Hospital, on Tuesday, the 5th Feb., Dr. ORANGE, of Broadmoor, in the Chair.

At the commencement of the proceedings, allusion was made to the death of Dr. Parsey, Medical Superintendent of the Warwickshire County Asylum, and a former President of the Association, and a resolution of condolence with his family was passed.

Dr. SAVAGE read a paper on

CONSTANT WATCHING OF SUICIDAL CASES,
which was followed by papers by Dr. GASQUET on
SOME OF THE MENTAL SYMPTOMS OF ORDINARY BRAIN DISEASE,
and by Dr. H. MAJOR on
THE RESULTS OF THE COLLECTIVE RECORD OF THE CAUSATION
OF INSANITY.

Considerable discussion arose on each of the papers.

LIVERPOOL MEDICAL INSTITUTION.

The ninth ordinary meeting of the Session was held on Thursday, February 14th, Dr. GEE, President, in the Chair.

Dr. ALEXANDER showed

CASES OF COLLES'S FRACTURE, WITH CASTS OF THE
DEFORMITY.

They were both taken from patients who met with the injury that produced the fracture some years previously, and who died in the Liverpool workhouse during the last few months. The first case shown had been treated by splints, but the second had practically never been treated at all. He also showed Gordon's splint for the treatment of the injury, and showed the method of applying it, remarking that it was the only form of splint that he knew of that gave satisfactory results, and that but few knew how to put it on. It was not so much known as it should be. He then showed a series of five calvaria thickened and more or less injured by syphilitic osteitis. In the first case the whole of the external and internal tables had been removed by necrosis. The patient died of exhaustion, and without any symptoms of brain disease. In the second, the necrosed part was over the frontal region, and the remaining parts were thickened by osteitis. In the third there was necrosis of both tables over a considerable area. In the fourth superficial caries had taken place over the frontal region, and in the fifth, the caries had extended over the whole of the outer table. He then exhibited two calvaria showing congenital malformations.

Mr. RUSHTON PARKER exhibited for Mr. Reginald Harrison a pathological specimen removed from a knee-joint in

the Royal Infirmary on the 12th inst. The patient was a woman, æt. 32, who, for two years, had suffered from what had been supposed to be suppurative arthritis of the knee-joint. She was admitted into hospital ten days before date of operation. At the commencement of the operation it was remarked that the case was not one of arthritis as had been supposed, but of sarcomatous disease of the lower end of the femur. The speaker remarked that the patient had for a long time been wearing a Thomas's splint; that this had covered up the diseased part, and had rendered diagnosis obscure, but that it had had a conservative effect, as it had kept the joint at rest and protected it from mechanical injury.

Mr. R. HAMILTON then showed a patient who had been the subject of

COMPOUND DISLOCATION OF THE ASTRAGALUS,
the point of special interest being the complete character of the dislocation and the completeness of movement recovered.

Mr. SHEARS related a case of

PANOPHTHALMITIS OCCURRING IN A NEGRO,
who was admitted into the Liverpool Eye and Ear Infirmary, under the care of Mr. Shadford Walker, on Dec. 6th, 1883. A week before admission he had an abscess on the front of his right forearm, with implication of the lymphatics and axillary glands; two weeks later, his left eye became acutely inflamed. On admission the man was very ill, and his left eye in a condition of acute panophthalmitis. There was no cardiac murmur. Temperature 104° F. The next day he had a severe rigor. On the fourth day a whistling bruit was heard just before the first sound at the apex of the heart; this murmur developed rapidly, and two or three days before death a very harsh double bruit could be heard all over the chest and back. On the ninth day he had another rigor, and first complained of severe vertical headache. He gradually became worse and worse, and died in a comatose condition on the 12th day after admission, at the age of 20. At no time had he any symptoms of implication of the lungs. He had no paralysis or convulsions. From first to last, the right optic disc remained quite healthy. At the post-mortem examination there was found to be an ulcer the size of a threepenny piece, with raised and rugged edges, just above the right cusp of the mitral valve, and perforating it. There were no infarctions of the lungs, liver, spleen, or kidneys. On opening the skull, purulent meningitis was found over the vertex and base, but no abscesses in the brain substance. The left eye was shrunken up and completely disorganised. Mr. Shears submitted that the case was one of so-called metastatic panophthalmitis, the primary focus being found in the abscess of the right forearm: from this septic emboli were carried to the vessels of the heart, causing an abscess just above the mitral valve, from this new focus the left eye became affected, and was rapidly destroyed. No cardiac murmur was heard when the man was admitted, but this was probably due to the fact that perforation of the valve had not yet occurred.

Dr. GLYNN showed some specimens of cardiac disease, additionally illustrated by numerous water-colour drawings. The first was one of aortic obstruction produced by a calcareous growth pressing on the root of the aorta. The patient had suffered from extreme dropsy, dyspnoea, and vomiting. At the post-mortem examination there was a difficulty in accounting for the severity of the symptoms at first, and until the calcareous deposit was discovered. Thickening of the endocardial membrane had taken place below the aortic valves, and the left auricle contained vegetations produced mechanically by the regurgitant wave. The pulmonary artery was three inches across, whilst the aorta was only two. The second was a case of cardiac hypertrophy from the high tension of renal disease. The third was a case of aneurism of the mitral valve, the anterior cusp projecting into the ventricle. Four and five were cases of ulcerative endocarditis which had been marked during life by persistent high temperature. The sixth was a case of fatty degeneration of endocardium resulting from anæmia.

CLINICAL NOTE ON KAIRIN.

Dr. ARCHER read a note describing a case of enteric fever in which kairin was used. A young male, æt. 19, was admitted to hospital in a desperate condition, almost moribund, with a rapid feeble pulse and a tendency of the temperature to keep up between 104° and 105°. Although the case terminated

fatally, the drug proved most efficacious in rapidly lowering the temperature. Thus, on one occasion after the administration of kairin, the temperature was found to have fallen more than a degree in a quarter of an hour, and on another a depression of over seven degrees was observed two hours after. It also had a beneficial effect on the pulse, usually slowing, steadying, and making it stronger. On several occasions the patient was apparently rescued from a state of collapse, with lividity of face and extremities, and placed in a condition of comparative safety and comfort, so much so that a faint hope of recovery was entertained. The anti-pyretic action was usually accompanied by rather profuse sweating. It was given in half-gramme ($7\frac{1}{2}$ grs.) doses every hour, with periods of remission, when the temperature was brought within bounds, and repeated when the temperature curves showed a marked tendency to rise. Half-doses ($3\frac{1}{2}$ grs.) did not appear to have much effect; a full dose had to be given after two or three hours trial with the smaller dose. Several published observations, principally of German authors, were referred to, which in the main agreed with what was noticed in this case. The patient was under treatment for only thirty-six hours, and during that time over 144 grains of kairin were given. It was used dissolved in mucilage and water.

Dr. BURTON stated that Dr. Queirolo, of Genoa, had lately been employing kairin subcutaneously, with the result that a much smaller dose was required, and its effects lasted much longer, than when given by the mouth.

Dr. ARCHER then replied.

THE VOLUNTEER MEDICAL ORGANISATION.

A DEPUTATION, consisting of representatives of Volunteer surgeons, the medical profession, teachers in the London medical schools, and others interested in ambulance work, waited on the Marquess of Hartington at the War Office, on Wednesday last, for the purpose of presenting a memorial on the further development of ambulance work in connection with the Volunteer forces. Sir T. Lawrence, M.P., introduced the deputation, among whom were Surgeon-General Sir William Hunter, Surgeon-Major Evatt, Major Gildes, Surgeon-Major Harvey Hill, Surgeon W. H. Platt, Surgeon Andrew Clark, Surgeon J. H. Casson, Lieutenant Macure, John Furlley, Esq., A. T. Norton, F.R.C.S., John Langton, F.R.C.S., J. E. Squire, M.D., G. H. Makins, F.R.C.S., J. Raw, Esq., J. Astley Bloxam, F.R.C.S., and Acting-Surgeon J. Cantlie. The Marquess of Hartington was accompanied by Major-General Elkington, Dr. Crawford, and Lord Morley.

Sir William Hunter drew attention to the objects of the Organisation, as follows:—

This deputation is desirous of drawing your Lordship's attention to the fact that, whilst the Volunteer force at present possesses a body of regimental surgeons, and to some considerable extent regimental bearers, no medical department and no hospital corps capable of working the divisional bearer companies or the field hospitals exist. It is to assist in developing some means of supplying this want that this Organisation has been formed.

This deputation believes that there should be no difficulty, in conformity with the spirit of the Volunteer regulations, to embody a medical corps, consisting of the same class as form the present combatant volunteers, which will supply this want.

The medical corps, when formed, would stand in the same relations to the Volunteer forces as the medical department and the army hospital corps do to the regular army, and this too, without necessarily interfering with the existing regimental medical arrangements of the Volunteer forces.

Judging by the success which has attended the work of this Organisation up to the present, and the interest taken in it by the public, and by the majority of the metropolitan medical schools, large numbers of whose students are now under training, this deputation believes that it only requires such assistance from the State as has already been given to various branches of the Volunteer force to assure its success.

The deputation desires to draw the attention of your Lordship to the fact that such a corps, besides making more complete the Volunteer army, will, it is anticipated, be the means one day of furnishing a trained reserve, capable of affording efficient aid to the country in time of foreign war; such a reserve forming an essential feature in a military service.

This deputation hopes that your Lordship will see fit to grant a capitation allowance to efficient members of the medical corps, and sanction the issue of ambulance *materiel* such as is issued to the medical service of the regular army, for use in the training of its members in ambulance work, and further that the recognised regimental bearers (2 men per company) as authorised by section xvi., paragraph 486, Volunteer Regulations, 1881, who have also qualified in ambulance drill in addition to military proficiency, should be granted an extra capitation grant for so qualifying.

Lord Hartington thanked the deputation for the information they had given him, and said their scheme seemed to have in it a very great possibility of advantage to the country and the Volunteer force, but there was a great deal yet to be thought out. They had better embody their proposal and send it in, and before any formal application was made there had better be some confidential communications between Dr. Hunter, General Elkington, Dr. Crawford, and Lord Morley, who had presided over a Select Committee on the subject of the medical service. Although he thought there would probably be great advantage from the elaboration of the scheme, he would not like to commit himself at present without further confidential communication. It would give him very much satisfaction if the details could be satisfactorily worked out, and in that case the deputation might rely on the assistance of the War Department.

The deputation thanked his Lordship and retired.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

THE INOCULABILITY OF PHTHISIS has been the subject of the meetings of the Academie de Medicine for the last three weeks, and on Wednesday last M. Verneuil mentioned a case which he believed to be eminently satisfactory to the theory. He began by remarking on the facility of inoculating certain animals with tuberculous matter, whilst in the human species the disease is considered to be generally the result of excesses, poverty, bad hygienic conditions, &c. This difference in his mind could not be regarded otherwise than fundamental. But he would not go so far as to say it was absolute, he would dare to say that the intrusion of tuberculous disease in man might also be the result of accidental inoculation, and he even thought that such cases were not absolutely rare. He was permitted to see several of the kind, amongst which was that of a young man, a dresser in the Children's Hospital, who, in making an autopsy of a child who died of pulmonary consumption, wounded himself in the back of the hand with the scalpel. A few days afterwards a little pimple occupied the site of the wound and gave exit to a drop of pus. In a short time other *boutons* joined the first and spread over the whole of the index finger, the skin of which was of an angry red and extremely painful at times. All kinds of medical treatment were tried without success, and, as a last resource, the patient applied to M. Verneuil in order to amputate the finger. The operation was done, and at the same time an abscess found on the back of the hand was opened, giving exit to characteristic tuberculous matter. The wound healed rapidly but the abscess gave considerable trouble. However, he returned to his studies and having taken out his diploma went to settle in the country. A short time afterwards two abscesses made their appearance in the lumbar region which were undoubtedly tuberculous, and up to the present they have not healed. M. Verneuil regarded this case as being similar to that of Laennec, who during the autopsy of a tuberculous patient had wounded himself, and a tumour followed which he destroyed with butter of antimony. Twenty-five years afterwards he died of phthisis.

THE OPERATION OF ESTLANDER.—At the Société de Chirurgie, M. Perrier communicated the observation of two patients attacked with purulent pleurisy with fistula consecutive to the empyema, upon whom he practised the operation of resection of the ribs, known as the operation of Estlander. The first case was serious, and two ribs only were resected, the patient succumbed. In the second, six were submitted to the operation with great benefit to the patient. M. Berger cited another case, that of a man of thirty, whose parents died of consumption and who had had pneumonia some time ago, and finally a pleuritic sero-purulent. At the hospital he was tapped once to his great relief, but, some time afterwards, it was found that the whole pleural envelope was filled with a liquid, the nature of which it was easy to determine. The operation of empyema was performed, giving issue to two quarts of pus, and, immediately the patient improved and the suppuration ceased for the time. However, a few months afterwards, hectic fever reappeared with dyspnoea and profound emaciation. It was at this point that Estlander's operation was decided upon as the last resource, and for this purpose a triangular piece was cut with the base posteriorly, which brought the intercostal spaces into view. Four inches of the ninth rib were resected, three and a half of the eighth, seventh, sixth, eleventh, and twelfth, the third, fourth, and fifth were similarly treated, but to a less extent. The pleural cavity was not opened, and the operation lasted an hour and a half. The patient succumbed a few hours afterwards. M. Monod and M. Séé reported each a case under their care, in which the results were most satisfactory.

DEATH OF DR. FABRE.—Medical science in France has suffered a severe loss by the death of Dr. A. Fabre, of Marseilles, and the poor of that town have reason to deplore his untimely end. Dr. Fabre was attached to the Hotel Dieu of Marseilles, and his clinical lessons were of such a superior kind, that his classes were always well attended even by his own *confrères*, who came to listen to a man unique in the Phœcean town. The *Gazette des Hôpitaux* profited largely by his contributions, and other medical journals were always glad to afford him space. It is not to be wondered that Dr. Fabre should have had a very extensive practice, but with all, he was able to find time to assist the poor, who twice a week crowded his door. His work of charity was so well known, and the strong religious principles he maintained, that he was commonly called amongst the lower class "Saint Fabre." He was offered several times the ribbon of the Legion d'Honneur, but being a strong Ultramontane he always refused, preferring the ribbon received from the Pope, and which always adorned his button hole. Dr. Fabre died suddenly at the age of 54.

THE highest annual death-rates in the large towns last week from diseases of the zymotic class were—From whooping-cough, 1·4 in Newcastle-upon-Tyne and in Bolton, and 1·2 in Huddersfield; from scarlet fever, 3·3 in Blackburn, 2·4 in Leicester, and 2·1 in Leeds; from measles, 2·3 in Birkenead, and 1·6 in Salford; and from "fever," 1·1 in Preston, and 1·0 in Newcastle-upon-Tyne. The 39 deaths from diphtheria included 19 in London, 6 in Glasgow, 3 each in Edinburgh and Birmingham, and 2 in Dublin. Small-pox caused 9 deaths in Birmingham, 4 in London, 3 in Liverpool, 3 in Sunderland, 1 in Wolverhampton, and 1 in Manchester.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 20, 1884.

THE IRISH COLLEGE OF SURGEONS AND MEDICAL REFORM.

THE Fellows of the College assembled at the special meeting on Friday last passed three resolutions hostile to any reform which would require the College to surrender any of its "powers and privileges," a phrase which is equivalent to the refusal of any reform whatever. The following are the resolutions, and they might readily be mistaken for a series of clippings from Dr. Kidd's letter in our last issue:—

"That this meeting approves, and will gladly support, a well-considered measure of reform calculated to remove such defects as have been proved to exist in the constitution of the medical profession; but, at the same time, the Fellows here assembled desire to express their conviction that it would be injurious to the public welfare, and an unjustifiable employment of State authority, to strip of their privileges institutions which can be shown to be using them both well and wisely."

"That, inasmuch as the Bill introduced into Parliament last session would, had it become law, have deprived this and other medical authorities of the power and influence over the profession which they have hitherto exercised, and which were conferred on them by charter, the Fellows of this College are of opinion that any such legislation should be resisted by the entire profession as being in a high degree injurious to its best interests."

"That this meeting having been informed that it is the intention of the Government to introduce into Parliament during this session a Bill similar to that of last year, recommends the Council to use all the influence it can command to obtain such changes in that Bill as may be necessary to preserve the chartered privileges of the College, more especially the right of conferring a title to practise; and failing this, to oppose the passing of such a measure by all constitutional means."

The first of these only was contested by the reform

party, who retired from the room as soon as it became obvious that the Fellows had been brought up for the purpose of putting their hand and seal to the "Huxley dogma," and were not disposed to listen to argument on the subject. The debate was prolonged and vigorous, but as the anti-reform party brought forward no argument additional to that embodied in Dr. Kidd's letter, and as the facts stated in support of their case by the reform party were chiefly those already presented to our readers, it does not seem necessary to occupy our columns with an extended report of the proceedings. The two following amendments were moved to the foregoing resolutions by Dr. Jacob and Dr. Corley:—

"That this College approves of the course pursued by this College as to the Medical Acts Amendment Bill of last session, and remits it to the Council to take such steps with reference to medical bills that may be introduced as may be necessary to protect the interests of the College."

"That, whilst disapproving of certain clauses in the Bill recently before Parliament, we are of opinion that legislative interference is absolutely necessary in the interest of the public, of the medical profession, and of such of the licensing bodies as have been mindful of their duties and responsibilities."

The fact that these very mild amendments were refused by the Fellows by a large majority is sufficient to show conclusively that the willingness for reform professed by the first resolution did not exist amongst them, and that they had come to the College for the purpose of voting the phrases put into their mouths, and nothing else.

This pronouncement of the meeting would amount to a very serious declaration of policy if it were to be accepted as the voice of the Irish College of Surgeons; but the circumstances under which the meeting was summoned, and the number of votes which decided the question, are such as to throw doubt upon the spontaneity of the movement and to detract from the importance of the pronouncement. Out of about 200 Fellows, who, without great sacrifices, might have been present, only 61 attended at any period of the meeting; while, out of 65 Fellows resident in the provinces, only 8 put in an appearance, many of those who signed the requisition for the meeting being conspicuous by their absence. The majority of 30 which voted against Dr. Corley's amendment consisted, we believe, of these 8 provincial Fellows and 22 metropolitans. This is, after all, not a very glorious victory for the anti-reform party, nor one which the Government need much regard, but, of course, it will have its influence on the Council of the College, and will strengthen the hands of those members who have urged a policy of opposition. We can only express the hope that the Bill, when it is introduced and printed, will be found to have been so modified from its last year's form as to take out of the hands of Dr. Kidd and his followers the weapons which they have used against a change for the better.

Into the debate at the Irish College of Surgeons an episode was introduced which all who desire fair discussion of great questions and who are concerned for the dignity of the College must regret. A statement prepared by Dr. Jacob for the purpose of showing the Fellows the falsity of the cry that the College would be extinguished if the Bill should pass, had been placed in their

hands, and certain of the speakers against reform—notably Dr. Kidd, Mr. Stokes, and Dr. Molony—failing any possibility of contradicting or refuting the facts submitted by Dr. Jacob, devoted themselves to personal abuse of him and those who acted with him. Dr. Molony pronounced these statements to be "at least greatly exaggerated," and Mr. Stokes declared them to be "scarcely honest."

Such phrases may, perhaps, be hardly worth notice. In the effervescence of rhetoric and in the agonies of oratorical parturition, persons unaccustomed to debate may be excused for giving utterance to such language, no matter how carefully they have prepared their speeches beforehand; but, when they have been guilty of a slip, they ought to be ready to make the *amende*, and to give as much credit to other people for truth and honesty of purpose as they would claim for themselves.

Dr. Kidd, however, transgressed all bounds of the decency of debate by directing the assembled Fellows that they must receive "with caution" the statements made by Dr. Jacob and his party, and by accusing these gentlemen of having deliberately perpetrated "inaccuracies" for the purpose of "misleading." Such a statement—intended, apparently, as an insult to his medico-political opponents—is calculated to degrade the College and the utterer of it more than anyone else.

The "caution" which was thus inculcated may perhaps be advantageously exercised by the Fellows of the College in respect to Dr. Kidd's dictation to them. Do they know the medico-political creed of their guide? Here it is, taken from his speech as President of the Dublin Branch of the British Medical Association, and published Feb. 4, 1882, page 148:—

"Let us give up the idea of protection. So long as we know and attend to our business, we need not fear the rivalry of quacks. Let Colleges and Universities cease to claim for their degrees, diplomas, or licences any privileges; let that which is certainly the case be openly avowed; let the public learn that no licence is necessary to enable any man to practise medicine."

This remarkable pronouncement is quite consistent with the free trade in diplomas which Dr. Kidd now urges upon the Fellows of the College. But the following paragraph seems hard to reconcile with his eulogy of the existing medico-educational system:—"It must be admitted, however, that the tendency of the system under which we are at present is to induce competition for candidates by lowering the standard of education and examination."

Add to this the remarkable avowals that the College should take homœopaths to its embrace, and that it is not its duty to do more than ensure that its licentiates shall possess the "rudiments" of their profession before sending them out, and we have a fair expression of the medico-political views of the present leader of the College. We respectfully advise the Fellows to accept his guidance with due "caution."

A BILL to regulate the practice of medicine and surgery was recently introduced in the General Assembly of Virginia.

THE PRISONS MEDICAL SERVICE.

ONE of our contemporaries has recently devoted a leader to, and published the following extract from, a letter written to the Commissioners of Prisons (England) congratulating them on the highly satisfactory nature of their Report:—

"The progressive decrease in the death-rate of the prisons, which has now reached 78 per 1,000 of the prison population (showing a diminution of 22 per 1,000 on the mean death-rate of the last ten years, which so lately as 1875 exceeded 14 per 1,000), is a striking proof of the successful care which has been bestowed on the health of prisoners, and the Secretary of State desires that his satisfaction may be expressed to the medical officers at these results of their efforts. Considering that the class of persons who are placed under their care are generally those whom vice and crime have rendered unhealthy subjects, this death-rate (even taking into account the number of diseased persons released on the score of ill-health) must be regarded as singularly low."

We congratulate the medical officers of English prisons on this recognition of their services. When the ordinary death-rate of the population is considered, we think there are few who would dispute the assertion that such a death-rate is low, and taking into account, as pointed out by the Home Secretary, that the class with whom the medical officers have to deal is principally recruited from those broken down by disease, depravity, and vice, the Home Secretary does not exaggerate when he describes it as singularly low.

Such results indicate not only skill and care in the treatment of the sick, but, what is no less important, that great care and attention must have been paid to the sanitary condition of the prisons. Gratifying as the recognition of their services by the Home Secretary must be, it appears that it has not been confined merely to words, but by a general increase of salary. This is as it ought to be. Good work deserves both commendation and practical recognition, and the policy is sound which, while rewarding valuable services in the past, stimulates to further exertions in the future. A sense of duty—and, we may say specially, a sense of professional duty—impels medical men to do their utmost to alleviate suffering and prevent the spread of disease. Human nature, however, exists under the doctor's gown, and gratitude in the sense of an expectation of favours to come, if it does not excite to renewed zeal in the discharge of duty, certainly makes its performance more pleasant.

This "highly satisfactory" state of affairs for the medical officers of English prisons naturally caused us to inquire, How fares it with their *confrères* of her Majesty's prisons in Ireland? Have they been congratulated on their successful skill? Have they received increase of pay? We regret to find they have not. On the contrary, increased work both temporary and permanent has been imposed on them, and although led to expect it, for the onerous duties inflicted on them under the Persons and Property Preservation (Ireland) Act they have been refused any compensation whatever, and although their duties are as onerous and their work as heavy as that of the English medical officers, their pay is far less. We are at a loss to discover the reason of this singular difference in treatment. We did not for a

moment suppose that less satisfactory results had been obtained in the Irish prisons, but if we had, the investigation of the reports of the General Prisons Board would have dispelled any doubts on that point, and the following facts culled from those documents prove conclusively that the "death-rate (even taking into account the number of diseased persons released on the score of ill-health) must be regarded as singularly low."

Neither the extract from the Home Secretary's letter nor the comments in the article state whether his remarks apply only to what are known as local prisons, or include convict establishments. The allusion to the discharge of diseased persons lead us to believe that the reference is to local prisons. We shall, however, give the death-rate for both in Irish prisons. In the year from 1st April, 1879, to 31st March, 1880, being the year after the prisons passed under the Prisons (Ireland) Act from the counties to the Government, the commitments to local prisons numbered 44,659; the deaths in that period, excluding executions, amounted to 23, or '51 per 1,000. In Feb. 1881-82: Commitments, 41,088; deaths, 18, or '43 per 1,000; and in Jan., 1882-83, the commitments were 35,434, and deaths, excluding executions, 7, or '19 per 1,000. The prisoners treated as sick during the same periods, both in and out of hospital, were—1879-80, 36,962; in 1881-82, 37,813; and in 1882-83, 30,740. In the convict prisons we find certain percentages given as to the death-rate which are quite unreliable with regard to the total number of convicts in prison, inasmuch as the percentage is only calculated in those prisons in which deaths occurred. We find, however, in 1879-80 the total number of convicts 1,064; deaths 9, or 8·4 per 1,000. 1880-81, 1,204; deaths 5, or 4·1 per 1,000. 1881-82, 920; deaths 7, or 7·6 per 1,000. 1882-83, 1,141; deaths 8, or 7·0 per 1,000. If the Home Secretary's letter merely refers to local prisons, then these results are immeasurably superior; if to both local and convict, we have a death-rate in England of 7·8—in Ireland of 7·2, and this, too, in the face of defective nursing and great difficulties.

We have frequently called attention to the many and serious grievances under which the medical officers of Irish prisons suffer. We need not now recapitulate them, more especially as they have been brought before the Royal Commission on Prisons Discipline, and we trust they may be remedied. But we would fail in our duty if we did not call for redress for what, if allowed to remain unremedied, would indeed be a gross injustice. The duties of Irish prison surgeons are both as arduous and extensive as those of English prison surgeons, and their responsibilities as great, while their salaries are much less.

The Government have justly recognised that English prison surgeons are underpaid, and have increased their salaries; the increase is not large, yet it is a recognition of the fact that for the work done the remuneration was not sufficient, and at the same time it has paid a well-deserved compliment to the efficiency of its officers. On what grounds of equity, justice, or policy are the Irish surgeons denied a similar recognition? Their work is as well done, yet they are worse paid. Instead of "satisfaction being expressed at the results of their

efforts" they are snubbed, and instead of increased salaries they are ordered to pay substitutes when absent on prison duty. We trust that the Irish members of Parliament will endeavour to see that justice is done to Irish medical men in this respect.

We have already expressed our conviction that the appointment of a medical member of the General Prisons Board and of a medical inspector of prisons was urgently needed. If anything were required to confirm us in that conviction, it is furnished by this example of the different policy carried out towards the prison surgeons in the two divisions of the United Kingdom.

KOUMISS.

SUFFICIENT experience has now been had of the virtues of Koumiss as a food remedy in many cases of disease, to render any defence of the preparation no longer necessary. Both in hospital and private practice so many and valuable advantages have been found to attend its employment that not a few physicians now regularly prescribe it in wasting diseases attended with gastric irritability, and inability of the patient to retain ordinary food. A number of cases in which it has proved exceptionally serviceable have been recorded—some among them being of a kind to demonstrate the fact that Koumiss may be regarded as a specific in certain instances where no other agent is found of any avail. Thus, in 1881, Dr. Sutherland reported to the Clinical Society of London that a female patient of his own, afflicted with chronic vomiting on account of which no kind of food could be kept on the stomach, was finally put upon a diet of Koumiss alone. This appeared to agree with her, and for sixteen months it alone formed the whole of her dietary, no other food of any description having been administered. Many other examples, almost as conclusive of the sustaining powers of the preparation, will at once recur to every reader, and the obvious teaching of such records is that an article so valuable ought to be much more universally employed than it has yet been. Against this course, however, is the considerable expense that may be incurred by any who propose to make an extended use of the preparation which, hitherto, has been thought to be procurable only from institutions where it is specially made. Thus obtained, the article becomes a luxury from the price which is charged for it, and we feel assured that were it but generally known that practically serviceable Koumiss can be manufactured at home, in any ordinary household, its properties would speedily become generally recognised and utilised; and yet this is thoroughly feasible, and has been proved to be so in more than one instance, especially in hospital practice, where, owing to questions of economy, Koumiss is less extensively used than might be the case in the interests of patients. In order, therefore, to enable those who may wish to make their own Koumiss, we consider that the mode of proceeding should be very generally made known; and the following directions are those which it is desirable to follow to ensure success:—

Take of milk (fresh), one gallon;
Koumiss, one quart bottle;
Pounded loaf sugar, two ounces.

Put the whole in a flat open dish, and submit it to moderate warmth for twenty-four hours, covering the dish with fine muslin for protection against dust, &c. An ordinary kitchen at night is a suitable plan for the operation of conversion to take place in, but care must be observed lest too great a degree of heat is employed during the process. At the end of the time named the preparation must be put up in champagne bottles, and the corks firmly wired down, and the bottles, after filling, should be left for another twenty-four hours in a warm cellar, prior to being used. In summer time care will have to be exercised lest the warmth be of a kind sufficient to burst the bottles when stored, and a little experience will readily enable this danger to be overcome. In order, further, to prevent any danger from bursting at the time of using the Koumiss, a napkin should always be placed around the bottles before opening them; but for purposes of convenience it is a good plan to draw the liquor as required by means of an ordinary champagne corkscrew-tap.

When once a supply of Koumiss has thus been made, future brews will be obtainable without having recourse to the purchase of the article for setting up the fermentative changes, since a bottle of the home manufactured material will always be equally serviceable, and thus, too, always accessible.

We shall be glad to receive reports of the success attending trial of this mode of preparation from any who adopt our suggestions; and to hospital managers especially, it may be cordially recommended to follow so simple a plan for providing patients with a valuable article of diet without at the same time straining the income of the charity to meet any additional expense thereby incurred.

Notes on Current Topics.

Nursing at Charing Cross Hospital.

AMONG hospitals at which open disagreements between medical and nursing staffs have threatened to breed mischief like that which has resulted in such harm to Guy's, Charing Cross is the institution most recently under notice. At this place, which, in common with King's College Hospital, has been nursed by women trained in connection with St. John's House, difficulties last year occurred, when the "ladies" followed the example set by those at King's, and deserted their posts in sympathy with the excitable matron of the latter institution, whose resignation was compelled at the instance of the hospital authorities. These sisters then severed their connection with St. John's House also, because their preposterous claim to rule in the wards as absolute mistresses thereof was not supported by the Council; and the treasurer at Charing Cross, like his brother official at Guy's, promptly espoused the cause of the recalcitrant women. Meanwhile St. John's House authorities replaced the rebels with other nurses, who have performed their duties respectfully, efficiently, and to the entire satisfaction of the physicians, surgeons, and resident staff of the hospital; but notwithstanding this Mr. Few, the treasurer in question, has endeavoured to obtain their dismissal from the charity, in order that their places may once more be taken by

those who last year so far forgot themselves and the sacred trust reposed in them. For some time this controversy has embittered matters at Charing Cross; and on Wednesday last it was finally settled for good by the action of the treasurer himself, who summoned a meeting of governors to consider his proposal so reintroduce a body of women with whom the staff had already declared it impossible they could work in union. Most fortunately for the interests of the hospital, the meeting plainly perceived the utter ruin that must ensue should the endeavour Mr. Few was making be successful, and his motion was defeated by an overwhelming majority, while the most perfect satisfaction with the present state of things was given expression to. We may thus hope that a decisive defeat has been sustained by that mischievous class of busybodies who delight to meddle with questions of hospital management, for the solution of which they possess no sort of capacity; but we may also assume that the disasters which have befallen Guy's as a result of permitting such interference of lay authorities, has done not a little to educate governing bodies in the way of perceiving the dangers which they ought to avoid. A treasurer can perform many duties wisely and well; but the moment he essays to exhibit a partisanship to the detriment of supreme medical authority in the wards of the hospital he is attached to, nothing but harm to the charity can result unless, as in the present instance, his own complete discomfiture terminates the difficulty.

The Aspect of the Cremation Question.

ADVOCATES of cremation may well congratulate themselves on the satisfactory change which has taken place in public opinion concerning the reform they seek to introduce in the mode of disposing of dead bodies. Within the last week two most important and significant occurrences have served to mark this progress—one, the announcement that Dr. Cameron will introduce a Bill into Parliament having for its object the legalising of cremation; and the other a definite statement from one of Her Majesty's judges to the effect that there is no law which forbids the decent disposal of human remains by fire. The occasion which evoked this expression of opinion was the trial of Dr. Price, "the Welsh Druid," on Friday last, at Cardiff, on a charge of unlawfully attempting to burn his dead child. The result was a verdict of not guilty, and in charging the jury Mr. Justice Stephen advised them that burning a dead body was not a legal offence in itself, and could only become a misdemeanour by being performed in such a way as to become a public nuisance. Possibly this may have a beneficial effect in influencing the public mind to consider the question with calmness when it comes to be subject of Parliamentary discussion in April next.

THE General Medical Council has been summoned to meet at 2 o'clock on Tuesday, March 25th, the Executive Committee the day before (March 24th), and the English Branch Council on the morning of March 25th. It is not known at present what business is to occupy the Council, or whether the Medical Bill is to be taken into consideration.

Volunteer Medical Organisation.

AN important and influential deputation had an interview on Wednesday last with Lord Hartington, for the purpose of urging on the Secretary of State for War the desirability of establishing a special medical corps of the Volunteer Service, to hold the same position in it as the Army Medical Department and the Hospital Corps hold in the regular army. The advantages of such an adjunct in time of war were pointed out by the deputation, and the arguments in support of it that have from time to time been urged in these columns were insisted on. Lord Hartington returned a very favourable answer to the deputation, and said that if a well-considered scheme were drawn up and forwarded to the War Office authorities, he would promise that it should receive every consideration; and although he was unable to make any definite promise in the matter, he thought it presented many features which would ensure its success. The deputation included Sir Trevor Lawrence, Bart., M.P.; Sir W. G. Hunter, Surgeon-General; Surgeon-Major Evatt, A.M.D.; and representatives from the various hospital ambulance corps which have been created through the indefatigable energy of Surgeon-Major Evatt in the metropolis.

The Bacillus of Cholera.

AT the last meeting of the Royal Medical and Chirurgical Society, held on the 12th inst., a special interest was aroused by the exhibition of a number of microscopic specimens, sent to the President by Dr. Straus, of Paris. These comprised sections taken from various parts of the small intestine of cholera patients, within a short period of death; and others, preparations of the rice-water stools, all being stained, with the object of bringing into view the organisms that might be present in them. Examination of the visceral preparations showed that the epithelial lining of the villi and mucous membrane of the part was completely desquamated, and also that large numbers of villi existed in the villous tissue and in the structure of the mucous membrane, thus lending confirmation to the discoveries already announced by Koch as the result of his Egyptian investigations. Dr. Straus, moreover, identifies the most frequently observed form of bacillus in his specimens as similar with that which Koch describes as resembling the bacillus of glanders, but he is careful to avoid any definite statement on the subject until he becomes aware by what particular method Koch's preparations were made. In the discussion which followed the exhibition of the specimens, considerable variety of opinion as to the probable nature of cholera was expressed, Sir Joseph Fayrer and Surgeon-Major Lewis emphatically declaring their belief that the disease was non-contagious. The latter further asserts that he has long been acquainted with the existence of micro-organisms in the rice water stools, and that he was convinced no single one of the forms of bacteria shown in the specimens could be said to be definitely associated with cholera. Probably the future history of this controversy will depend to a great extent on the success attending Koch's Eastern investigations; but whatever other result they may have, there can be little doubt of

the benefits to science that will result from continuance of the discussions.

Society for Relief of Widows and Orphans of Medical Men.

An extraordinary court of directors of the Society was held on January 23rd, to receive the resignation of Sir George Burrows, Bart., President, Sir Henry Pitman, V.P., in the chair. Mr. Charles Hawkins, V.P., moved, Dr. Quain, Treasurer, seconded, the following resolution:—

"The court of directors in accepting the resignation of Sir George Burrows as President of the Society, desire to place on record its high appreciation and sense of the valuable services he has rendered in this capacity. The constant watchful and benevolent interest which for seventeen years, as President, he has taken in the affairs of the Society, has in a great measure contributed to its successful management and its present prosperous condition, and this court feels confident that Sir George Burrows on retiring from the office of President, will carry with him the affectionate regard of the entire court of directors, and the esteem and gratitude of every member of the Society."

Mr. Charles Hawkins moved, Dr. Quain seconded,—

"That Sir James Paget, Bart., be nominated as President in place of Sir George Burrows, Bart., resigned, and that an extraordinary general meeting be called for Friday, February 8th."

In accordance with the above resolution, an extraordinary general meeting of the Society was held on February 8th, Dr. Harvey Owen, V.P., in the chair, and Sir James Paget, Bart., was unanimously elected President of the Society. The members present adopted the resolution carried at the extraordinary court of directors on the resignation of Sir George Burrows, Bart., and requested the Secretary to forward a copy of it to the late President.

Bichloride of Mercury in the Treatment of Gonorrhœa.

DR. JOSEPH MCCHESENEY, Denning, New Mexico, Surgeon to the Atchison Zopeha and Santa Fe Railway Co., reports the results obtained in the treatment of gonorrhœa by a solution of corrosive sublimate of the strength gr. j. to ʒvj. of water. In some of the cases he tested the differences in treatment by, at the onset, exhausting old and well-tried formulæ for injections in obstinate cases, and then using the bichloride of mercury in the strengths mentioned. In all the cases noted the results were everything that could be desired. In all the patients were cured of the discharge within ten days of the commencement of the treatment. Should any of our readers have the opportunity of putting this method of treatment to the test of clinical experiment, it is desirable that the results should be recorded. Gonorrhœa, like toothache, is still one of those unsatisfactory complaints for which there are a variety of remedies, the action of which, however, are not as reliable as they might be. The writer has had most satisfactory cases, in which rapid and permanent relief was obtained by the injection of a solution of four drops of solution of permanganate of potash (BP) in two ounces of water. One case especially was almost ludicrously rapid in its recovery after this method of

treatment was employed. The patient had been six months a sufferer, and had tried a great variety of treatments under various men. On commencing the injection of permanganate, he was perfectly cured within twenty-four hours, and no subsequent relapse. Certainly this injection is most useful, and almost invariably controls, if not cures, the discharge.

Dr. McChesney directs the injection to be used every four hours. Dr. McChesney's experience accords with that of Dr. Tutakow, who read a paper upon the subject before the Berlin Charite Medical Society, noticing Messor's discovery of gonorrhœal bacteria, and recommending the use of a solution of the perchloride 10 parts in 20,000 to 30,000.

Dr. D. Campbell Black, of Glasgow, whose paper appeared in the *British Medical Journal*, March 10, 1883, p. 456, uses a solution gr. ij. of the perchloride to ʒviij of water. He has never known an uncomplicated case of gleet resist this method of treatment.

Doctor's Signs.

In a very interesting article the *Canada Medical Journal* presents some facts respecting doctor's signs as the editor has observed them in Canada, &c. From this and other statements we learn that in Canada the doctors have a way of erecting signs not common in the States or in this country. Thus the writer says he is acquainted with two signs in the shape of a metal door plate two feet square with five inch letters on the same. He quotes a remark of a well known American physician as he passed the office of a prominent regular Canadian physician over whose door there was a large transparency with the name and number of the doctor, "irregular, eh." He objects also to the following titles placed upon the sign or door plate, "Dr. ———, M.D. Edinburgh (Honors), M.R.C.S. Eng., L.A.H. Dublin." These are reported as quite common. But the latest novelty is a fine large block of granite such as would be suited for a tombstone, with the doctor's name cut in large letters on each side and the block placed as a carriage step in front of the doctor's office.

Sir William Guyer Hunter, K.C.M.G.

WHEN, at a recent meeting of the Epidemiological Society, the announcement was made by Sir Joseph Fayrer that her Majesty had signified her intention to confer upon Surgeon-General Hunter the dignity of Knight Commander of the Order of St. Michael and St. George, the round of applause with which the information was received sufficiently attested how completely the professional brethren of Dr. Hunter accorded with the recommendation on which the decision of her Majesty rested. It is honourable to Dr. Hunter himself that he so satisfactorily and well fulfilled the important mission on which last autumn he was sent to Egypt as to justify his patron in recommending him for the dignity which is about to be conferred upon him. It is also honourable to that patron that he took action with a view to those important services being thus acknowledged. Surgeon-General Hunter is a member of the Indian Medical Service. His official career in that country was peculiarly

successful. For many years he resided in the city of Bombay, where he held in succession a number of responsible and high positions in connection with the Civil Hospital and Medical School. He took a very active part in the sanitation of that capital, as also in its general improvement, and, further, if we mistake not, was for some time President of its Municipal Council. His period of actual medical administration was short, the latest new Regulations relating to the Indian and Army Medical Services having enabled him while comparatively young and in the full enjoyment of energy to accept retirement. A new sphere of usefulness now opens before him, and we cordially wish him many happy years to work and to enjoy the honours he has so well merited.

The Hunterian Society.

ON Wednesday last, Dr. George Roper delivered the annual oration in memory of Hunter, in the theatre of the London Institution, before an appreciative audience. The address was not confined to the customary laudation of the illustrious person whose name both the society and oration were designed to perpetuate, but embraced matters of practical import to the practitioner and student of medicine of to day. After the oration a cordial vote of thanks was accorded Dr. Roper for his eloquent address, which we hope to give in a future number. On the Friday following, the annual Hunterian dinner was held, under the presidency of Mr. Walter Rivington, of the London Hospital, when there were present Sir Andrew Clark, Dr. Braxton Hicks, Dr. Roper, and many other eminent members of the profession.

The Army Medical Service and Egypt.

CONCURRENTLY with the despatch of troops to the seat of war is a general movement in the medical and hospital departments of the Army and Navy. Last week we announced the promotions and appointments in the naval service; this week will witness the departure of some twenty army surgeons; and we understand that Surgeon-General Gilborne, principal medical officer at Aldershot, has received instructions from the War Office directing him to have ready for immediate embarkation a detachment of the Army Hospital Corps, consisting of six officers and about forty rank and file, to join the Soudan field force.

Mr. Croly, of Dublin.

THE return of Mr. Croly to his duties as Surgeon of the City of Dublin Hospital after his recovery from a prolonged and dangerous attack of typhoid was made the occasion of a demonstration of regard and appreciation by the students of the hospital, and also by the Board of Directors. An address was presented to Mr. Croly on his first appearance in the operating theatre, expressive of the affection of the class for him and their satisfaction at his restoration to professional work, and it was replied to by Mr. Croly in suitable terms. The congratulations of the Directors were also well timed and cordially expressed, and we may venture to add our own felicitations upon Mr. Croly's escape from so great a danger.

Improved System of Wood Paving.

WE have to congratulate a well-known member of the profession, Dr. J. McGrigor Croft, late staff surgeon in the army, and now a guardian of the important metropolitan parish of Marylebone, upon the initiation of a new system of wood paving. From what we understand of Dr. Croft's principle of wood-block laying, it is entirely different to any plan in use. The blocks so laid drain themselves of moisture, never burst up, as we see in the puddles of water and dirt that remain after heavy rain in the indents of swollen wood. The passage of vehicles is noiseless, and the horses have a dry grip at all times, which will prevent that sliding and falling now so common on wood and asphalt roads. The cost of laying wood on Dr. Croft's principle is stated to be far less, and will last longer than any other, an important item for ratepayers. We hear the plan has been tried on a heavy thoroughfare and pronounced a great success.

Royal College of Surgeons of England.

AT a meeting of the Council of the College on the 7th inst. it was decided to submit to the Fellows and Members of the College the alterations proposed to be made in the Charter. It will be open to them to discuss such alterations and to recommend further change. This action on the part of the Council is due to the notice of motion given by Mr. Erichsen, and which we have reason to believe an attempt was made to burk.

The Electric Light.

ABOUT two hundred members of the Royal Society of Physicians of Vienna met on the 8th inst. in the auditorium of Professor Stricker's laboratory to witness demonstrations by the electric light. Before the commencement of the proceedings Professor Stricker gave a short explanatory introduction, to the effect that the apparatus was worked by a six-horse power engine located in the underground premises; that the current could be used for lighting the hall (20 Swan lights), or turned into the microscope camera for the purpose of projecting the microscopic image on the screen. The light was collected by a single large lens, and the carbon points of the light were regulated by screws worked by hand, as this plan gave a steadier light than could be got by clock-work apparatus. His assistant, Dr. Gärtner then came forward and projected the microscopic image of the mesentery of a living frog upon the screen, showing the circulation in the vessels, and also demonstrating to the audience the contraction of the vessels produced by the heat of the concentrated rays of light. At first the vessels were wide and the current rapid, as arrangements had been made for protecting the delicate living tissues from the heat; but no sooner was the protection removed than both arteries and veins began to contract, and in the course of about two seconds the arteries had contracted to such a degree that their lumen was obliterated, and the blood current was brought to a standstill. "Our observations," said Dr. Gärtner, "thus prove that an elevated temperature acts as an irritant upon the blood-vessels, that in consequence of this irritation they contract powerfully, even to total obliteration of their lumen. The fact well known to physicians, and especially to

gynaecologists, of the hæmostatic action of heat finds in these observations an experimental foundation."

Professor Stricker then gave an address on the structure of tendons, illustrated in the same manner, and afterwards Professor Kundrat demonstrated by the same process a series of pathological preparations. The whole of the proceedings elicited the liveliest interest.

PROFESSOR FLOWER, F.R.S., will commence a course of nine lectures on "The Principal Types of the Human Species," at the Royal College of Surgeons of England on Monday next, Feb. 25th, to be continued Wednesdays, Fridays, and Mondays, at 4 o'clock each day. Members of the profession will be admitted free on presentation of their cards.

THE Lords of the Admiralty have decided to abolish the present staff of hospital nurses, and to replace them by men chosen from the Fleet, who are to receive special training at the hospitals. They will thence be drafted to sea, but, on paying off, will return to their hospital instead of being sent to the dépôt ships as at present.

THE Liverpool poisoning case, which has been adjourned several times during the past few months, was concluded on Saturday by a verdict of wilful murder against the two women, Higgins and Flanagan, who stood accused of administering arsenic to divers persons (the husband being the victim in one case) for the purpose of obtaining money on insurance policies after the death of the said persons.

DR. PRICE was again placed upon his trial for the partial cremation of his illegitimate child, at Cardiff, on Saturday, the Jury having disagreed on the previous night. Counsel for the prosecution having elected to offer no further evidence, the Judge, in discharging Dr. Price, said he hoped that in future he would have more regard for people's feelings, while the public might make allowance for his eccentricities.

WE are asked to announce that a Bill will be introduced by Mr. Coleridge Kennard for the withdrawal of grocers' and other shopkeepers' licences for the retail sale of spirits and liqueurs. The Bill is under the auspices of the Church of England Temperance Society; but with every wish to help forward legislation for the control and suppression of drunkenness, we must honestly express our conviction that the withdrawal of the grocers' licence is tantamount to handing the liquor traffic over entirely to the publican.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 32, Madras 46, Paris 25, Geneva 27, Brussels 23, Amsterdam 29, Rotterdam 23, The Hague 21, Copenhagen 22, Stockholm 25, Christiania 25, St. Petersburg 40, Berlin 22, Hamburg 26, Dresden 25, Breslau 29, Munich 30, Vienna 25, Prague 40, Buda-Pesth 30, Rome 28, Turin 28, Venice 32, New York 21, Brooklyn 20, Philadelphia 21, and Baltimore 23.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 20·6 per 1,000 of their aggregate population. The death-rates in the several towns were:—Wolverhampton 15; Bolton 16; Bristol, Derby 17; Portsmouth 18; Halifax, Hull, Blackburn, London, Sunderland, Birmingham 19; Nottingham, Bradford, Brighton 20; Huddersfield, Leeds 21; Edinburgh, Sheffield, Plymouth, Salford 22; Liverpool, Norwich, Newcastle-on-Tyne 23; Leicester, Cardiff, Preston, Birkenhead 24; Oldham 25; Glasgow 26; Manchester 27; Dublin 30.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

DEBATE ON ALBUMINURIA AT THE PATHOLOGICAL AND CLINICAL SOCIETY OF GLASGOW.—A very important meeting of this Society took place in the Faculty Hall, Glasgow, on Tuesday night, the 12th inst. Dr. MacCall Anderson presided, and there was a large attendance of the profession. The subject to be considered by the Society was "Albuminuria, its Pathology and Clinical Significance," which was ably introduced by Dr. Newman. Dr. Newman dwelt especially on the anatomy and histology of the kidney, basing thereon his subsequent deductions. He believed that normally albumen escaped through the Malpighian capsule, but that it became absorbed in passing along the convoluted tubes. He contended that there was no such thing as normal albuminuria. Dr. Roberts, of Manchester, in a very able address, followed Dr. Newman, confirming his observations, especially to the clinical aspects of albuminuria, and to the tests by which its presence is discovered. In contradistinction to Dr. Newman, he maintained that there was such a thing as normal albuminuria, and he dwelt on these puzzling cases of the disease, even complicated with cardiac complications which get well. He referred to the urine test for albumen proposed by himself, the sodium tungstate test as recommended by Dr. Oliver, of Harrogate, the picric acid test recommended (but certainly not first introduced, as many will unjustly persist in writing and speaking) by Dr. Johnson, and other tests. As the result of a re-examination of the whole question, Dr. Roberts confessed that, after all, the old test of heat and nitric acid was the most valuable and most delicate one for albumen. Heat alone discovered albumen in urine where no other test did. Dr. Roberts' address was listened to with marked and deserved attention. Professor J. D. Hamilton, of Aberdeen, was the next speaker, and his address was a singularly lucid, brilliant, and suggestive one. He reviewed the various Continental opinions on the subject under discussion, the histological difficulties with which the question is surrounded, and his explanation of the thickening of the arteries and enlargement of the left ventricle was exceedingly ingenious and plausible. His whole address betokened great and extensive familiarity with his subject, and his deductions bespoke the cultured and cautious logical mind. After a sitting of two hours, which seemed a very short time, Professor Gairdner in a graceful and generous manner proposed a vote of thanks to the lecturers, which was heartily accorded. We purpose reverting in detail to this important discussion. It is to be resumed on the 19th inst., and it is announced that Professor Greenfield, of Edinburgh, and Dr. Mahomed, of London, are to take part in it.

THE TERCENTENARY OF THE EDINBURGH UNIVERSITY.—The Lord Provost's Committee of the Edinburgh Town Council had before them on the 14th inst. a request by the University Senatus for their co-operation in reference to the forthcoming centenary celebrations, so as render them as successful and as worthy of the occasion as possible. The Committee agreed most heartily to give every assistance in their power, and remitted to a sub-committee to place themselves in communication with the Senatus on the subject. The celebration is to extend over Wednesday, Thursday, and Friday, 16th, 17th, and 18th of April, and provisional arrangements have, so far, been completed.

EDINBURGH.—HEALTH OF THE CITY.—For the week ending with Saturday, the 9th inst., the mortality in Edinburgh was 95, and the death-rate 20 per 1,000. There were 19 deaths under 1 year and 26 above 60, of which 4 were above 80 years. Diseases of the chest accounted for 50 deaths, and zymotic causes for 19, of which three were due to fever, 4 to scarlatina, and 6 to measles. The intima-tions of these diseases for the week were 3, 43, and 158 respectively.

GLASGOW DEATH-RATE.—The deaths in Glasgow for the week ending with Saturday, the 9th inst., were at the rate of 27 per 1,000 per annum, as against 23 in the preceding week, and 23, 28, and 33 in the corresponding periods of 1883, 1882, and 1881 respectively.

FATAL MEAT POISONING CASES AT GOVANHILL, GLASGOW.—The question of meat poisoning to which attention had been directed by Haber in 1878 (*Archiv. der Heilkunde*), forces itself again on the public by somewhat extensive poisoning from this cause at Govanhill, Glasgow. Up till the present moment two deaths have been reported, while no less than eleven other persons have suffered severe sickness, though no more fatal results are anticipated. The particulars, as reported to the police, and the result of inquiries made by Detective Davidson, are as follows:—Robert Miller, nine years of age, son of Robert Miller, residing at 60 Inglefield Street, died on Monday afternoon, shortly after partaking of a small portion of the tinned meat. No suspicion of having been poisoned seems to have entered the minds of the boy's parents, and the body was interred. On Wednesday night John Webster, two years of age, a nephew of the seller of the meat, and son of a butcher, residing at 36 Inglefield Street, died after a short illness. In his case it has transpired that he also ate a small portion of the tinned meat a short time before his death. Dr. Robt. W. Forrest was called in, and certified that death resulted from poisoning, and after making an examination gave it as his opinion that the poison was contained in the tin. The boy Miller's mother and brother partook of the mutton at the same time, and they, too, were similarly affected, but afterwards recovered; and are now considered out of danger. From inquiries made by the detective, it has been ascertained that eleven persons, in addition to the two boys who died, had consumed a small portion of the meat. In each case sickness ensued, accompanied by vomiting and purging, but none of them are now considered in danger.

"THOUGHT-READING."—In our last impression there is a paragraph on this subject, one which has recently engaged a good deal of attention from medical men both in Edinburgh and Glasgow; and after having seen Mr. Stuart Cumberland perform his experiments, we are constrained to admit, no less in justice to him than to ourselves, that the paragraph in question fails to do him justice, and that it was written from the sceptical point of view, perhaps characteristic of medical men in matters relating to preternatural phenomena, a con-

dition of mind, however, rather praiseworthy than otherwise, while on rare occasions it may be pushed unconsciously too far. We are not going to cavil, as does one of our local contemporaries, with Mr. Stuart Cumberland for the use of the term "Thought-reading;" we think upon the whole the term is fairly allowable. The charm of Mr. Cumberland's exhibitions consists in his transparent honesty of purpose, and in his exposing by perfectly natural means the fraud of "Spiritualism," for which we have been indebted to our Transatlantic cousins, with so many other things good and bad, and which, we agree entirely with Mr. Cumberland, has done so much to subvert the highest and best interests of religion and morality, and has driven not a few to lunatic asylums. Of course it is hardly necessary to remark that few people of any intelligence believed that the phenomena accredited to so-called "Spiritualism" were caused through the agency of disembodied spirits; indeed, should such tricks constitute part of their celestial recreations, few sensible people would envy them their existence or their pastimes; but the question, on the other hand, arose, How are these phenomena produced? Rapping ("spirit rapping") constituted one of the phenomena of spirit presence and action, and answers were given according to a certain number of knocks as agreed upon between the medium and "spirit." Now, Mr. Stuart Cumberland demonstrates that he can produce these mysterious raps without disturbing the repose of disembodied spirits, and in possibly a more vulgar fashion. He possesses the power, in common with spirit media, of partially dislocating the joint of the great toe, through the action of the *peroneus longus* muscle, and thereby producing perfectly distinct and audible "spirit" knocks. This doubtless required long practice, and an unusual development of the muscle in question. But of Mr. Stuart Cumberland's demonstrations by far the most wonderful are his ability in a very large percentage of instances of discovering objects hidden through the agency of touch. Of collusion, we may remark, we are satisfied there could be in the instances to which we were witnesses be absolutely none. Thus, a pin was hidden in a particular place, and within an umbrella in St. Andrews Hall (Glasgow). While the pin was being hidden Mr. Cumberland left the Hall. Taking the gentleman who hid the pin as a medium, and blindfolded, Mr. Cumberland sallied forth in this great hall, and before a large audience, to find the secreted object—a test one would have thought in all conscience a trying one of his power. It is a condition of success admitted by Mr. Cumberland that the medium must concentrate his thoughts on the object of search, to the exclusion as much as possible of any other thought. In this instance there was a little bungling about the localisation of the pin; it was removed from the position in which it was originally placed, yet with the knowledge of the medium; and this makes Mr. Cumberland's success all the more striking. After wandering about the hall for a little with his medium, Mr. Cumberland was seen to hover about the place in which the pin was originally placed, and, not finding it readily, he said there must have been something strange as to the conditions of the experiment. It was remarked that he was very near the spot, when, in a few minutes, amidst great applause, the hidden pin was produced. In like manner Mr. Cumberland invited Dr. Neil Carmichael to think of some person among the audience. Dr. Carmichael did so, told the chairman the person in question (a gentleman whose name even was unknown to Dr. Carmichael), and, blindfolded, Mr. Cumberland led Dr. Carmichael to the gentleman thought of. Though not quite so successful in discovering the number of

a bank-note on this occasion, Dr. Carmichael being, according to Mr. Cumberland, a bad medium, still his partial success was very surprising, three out of the five figures on the note being accurately given. It is but fair to say that with Dr. McGregor Robertson, on a previous occasion, the operator was entirely successful. In like manner, Mr. Cumberland cleverly showed how the cabinet phenomena were entirely due to muscular ability. On these, which are the less surprising, we cannot afford space to enlarge. To medical men Mr. Cumberland's demonstrations are in the highest degree interesting, as attesting to the extraordinary extent to which the muscular sense may be developed. The condition as between the operator and the medium, as Dr. Yellowless observed to us, is one allied to hypnotism—a subordination of the one will (that of the medium) to another (that of the operator). It will be obvious that in a large hall, and before a numerous audience, the difficulties must necessarily be increased, and that to be successful to the extent that Mr. Cumberland usually is implies an amount of self-possession which very few command. Mr. Cumberland claims only to interpret an unconscious muscular action on the part of the medium, so far as we can understand, and he does it with marvellous success. The mysteries with which clergymen in Edinburgh invested his clever exhibitions are matters simply to be laughed at. As an accomplished exposé of a silly and pernicious fraud, Mr. Cumberland has our entire sympathy, and we have every confidence in recommending such of our professional brethren as have not yet seen him perform to make themselves acquainted with the striking manifestations he has to show.

A NOVEL THEORY OF VOICE TRAINING.—Under this heading we gave an account in our issue for Jan. 2nd of a lecture in Glasgow, by Dr. Moffat, on "Voice Training by Chemical Means," that gentleman having maintained that the presence of peroxide of hydrogen in the air and dew of Italy had intimate connection with the beauty of Italian vocal tone. In opposition to this absurd theory, Mr. Lennox Browne, F.R.C.S.Ed., delivered a lecture on Thursday evening last, in the rooms of the Society for the Encouragement of the Fine Arts, proving that, so far from Italian voices being in a majority, but a small minority of singers in Italian opera were of that nationality. Analysed into its constituent properties, it was shown that hydrogen in a marked degree caused deterioration of voice, while oxygen undiluted must have the effect of unduly exciting the membrane of the air passages. Still, further, there was nothing to show that this peroxide of hydrogen existed in a greater proportion in the towns and cities in Italy than elsewhere; on the contrary, the air in the majority of Italian towns was most insanitary. Still further analysing this artificial air, it was shown that, supposing the peroxide to have any beneficial effect, it was combined with two ingredients—ammonia (a most poisonous gas) and peppermint, which must necessarily render the preparation more unstable than it naturally is, and the conclusion was come to from the different points of view of chemistry, physiology, and actual practice, that the scheme was unworthy the slightest consideration of scientific men.

The office of Medical Officer to the Bank of Ireland has become vacant by the resignation of Dr. Rutherford Kirkpatrick. The appointment is worth at least £150 a year, and is appointed to by the Society of the employees of the Bank, not by the Directors.

THE CENTENARY OF THE IRISH COLLEGE OF SURGEONS.

ON Monday, the 11th, the President of the College, Mr. Wheeler, celebrated the 100th anniversary of the incorporation of the College by a banquet, at which he entertained the Lord Lieutenant, Earl Spencer, and the Heads of Departments in Ireland, as well as the officials of the College. The dinner was laid in the Albert Hall for about 180 guests, amongst whom were the Lord Chancellor, the Lord Justice of Appeal, and others of Her Majesty's judges, Mr. Brooks, M.P., Sir Arthur Phayre, Lord Clarina, the Provost of Trinity College, the Presidents of the College of Physicians, Academy of Medicine, Irish Medical Association, and Royal Hibernian Academy, Sir Robert Jackson, the Governor of the Apothecaries' Hall, the Medical Commissioner of the Local Government Board, and most of the leaders of the profession in Ireland.

The entertainment was in all respects a complete success. His Excellency proposed the toast of "The College of Surgeons," coupled with the health of Mr. Wheeler, who, in replying, gave a brief history of the College, and referred to the various epochs of its progress in very happy terms. The speeches of His Excellency were admirably conceived and delivered, and that of the Provost notable for its intellect and character. The music was excellent, and all the adjuncts of the entertainment of the highest order.

The President may congratulate himself on having taken out of the hands of the Council and effected so successfully the celebration of this very auspicious and now historical event.

Correspondence.

THE FELLOWSHIP OF THE LONDON COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The issue of the "List of Fellows, Members, Extra Licentiates, and Licentiates of the Royal College of Physicians" (London) for this year leaves one in still deeper mystery as to the line of action of the College in the selection of its Fellows. As regards the Members and Licentiates, an examination has to be passed successfully. But upon what principle the Fellows are chosen is an enigma to an outsider. It would be invidious to select the names of those who have been made Fellows since this decade came in; but it may be stated that of the thirty-nine selected only nine have any claim to be considered as well-known members of the profession; possibly some would limit that as a too liberal allowance. Now there can be no objection to mentioning the names of some well-known men who still remain on the list of members. Taking them as they stand, chronologically, we find—

- 1844. James Henry Bennett, the author of several works on the Uterus, on Consumption, on Nutrition in Health and Disease, &c.
- 1851. Arthur Hill Hassall, author of works on Food and on Microscopic Research, &c., a famous analyst.
- 1853. Jabez Spence Ramskill, a well-known physician, and contributor to the System of Medicine.
- 1857. Horace B. Dobell, author of works on Thoracic Disease, and Food.
- 1859. James George Davey, the author of "The Ganglionic System of Nerves," and of "Insanity," &c.
- Charles H. Felix Routh, who has written on Uterine Disease, Overwork, &c.
- Edward John Tilt, author of "The Change of Life," "Uterine Therapeutics," &c.
- Edgar Shepherd, an authority on Insanity.
- Robert Greenhalgh, author of several works on Diseases of Women.
- 1860. Julius Althaus, author of "Diseases of the Nervous System," "Use of Electricity," &c.
- Sir Wm. Smart, author of many contributions on Military Medicine.

1862. Charles Robert Drysdale, author of "Syphilis," "Antecedents of Consumption," &c.
 1864. Morrell Mackenzie, a well-known authority on Diseases of the Throat.
 1865. Heywood Smith, author of several gynecological works.
 1867. William Henry Day, author of "Headaches," and "Diseases of Children."
 — Prosser James, author of works on the Throat, on Climate, and on "Mineral Waters."
 1871. Lyttleton Forbes Winalow, author of works on Insanity.
 1872. Thomas Crawford Hayes, known in connection with Diseases in Women and Children.
 — J. Milner Fothergill, author of works on Therapeutics, on the Heart, and Gout, &c.
 1874. Clement Godson, an authority on Diseases of Women.
 1875. Edward Mackey, author of works on Therapeutics, and on Climate.
 — George Ernest Herman, favourably known as an authority on Diseases of Women.
 1877. Fancourt Barnes, author on Obstetrics, and Translator of a German Lexicon.
 — Vincent Harris, joint author of well-known "Manual for the Physiological Laboratory," &c.
 — Samuel West, author of "How to Examine the Chest."

1878. George H. Savage, an authority on Insanity.

Such are some at least of the men not unknown in the medical world who have been Members of the College long enough to be eligible for the Fellowship.

It is certainly not contributions to medical science that is the test, that is evident!

It is equally clear that unprofessional conduct cannot be alleged against the bulk of the names mentioned.

Is it social position? That does not seem very clear.

Connection with a teaching hospital cannot be the requisite, that is obvious.

What, then, in the name of wonder, is the test by which this mysterious body selects from its Members for the Fellowship?

Something was said a little time ago about a new regulation by which the claims of Fellows to be elected would be enumerated when chosen: the next list will perhaps indicate some outline of the principle by which the selection is guided. The selection of its Fellows was a matter on which an ex-President was very eloquent not many years ago. If their choice could be explained to the medical world some puzzled men would be enlightened, of whom the writer is one.

Yours, &c.,

M.D.

Feb. 14, 1884.

THE EMIGRATION OF STUDENTS TO SCOTLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At the recent meeting of the Fellows of the College of Surgeons of Ireland the speakers against the Medical Bill, finding it necessary to their case to show that the existing system of licensing was as nearly as possible perfect and needed no change, sought to discredit the proofs offered by me as to emigration of students to Scotland. Dr. Kidd thought fit to caution the Fellows against believing my statements, and declared that "inaccurate" assertions had been knowingly made by me for the purpose of "misleading," while Dr. Molony and Mr. Stokes—without advancing any refutation of them—described my statements as "exaggerated" and "scarcely honest." Dr. Kidd assured the Fellows that, if such emigration existed, it was caused by the fact that a double diploma is granted in Scotland and not elsewhere. It is, in my opinion, quite unjustifiable that such observations should be made by speakers who had the same sources of information as I had, and did not think it worth their while to examine into the subject before making public statements so offensive to me. However, lest the Fellows of the College should be influenced by Dr. Kidd's remarks, I beg you to permit me to quote as proofs the following excerpts from the testimony given before the Royal Commission on this point:—

Sir James Paget (Question 241): And I fully believe from all I have heard—but I am bound to say that it is only by report—that they (the Scotch College examinations) are at too low a standard. Again, I have to admit reports which I am bound to believe, that in the Scotch corporations they are

admitted too low. The reports are distinct statements that the worst of the students in England go to Scotland; that the worst of the students, especially in provincial schools, do not come to the College of Surgeons of England, but go to the College of Surgeons of Edinburgh, or to the Faculty of Physicians and Surgeons in Glasgow. I have never heard any statement of that kind with regard to Ireland.

Mr. S. Gamgee: I have known many men who have been unsuccessful in the English examinations once, twice, and thrice, go across the border and come back with the double qualification from the Edinburgh or the Glasgow Colleges. With regard to the Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, I have known men get through there who had failed in our College of Surgeons repeatedly, and I have no hesitation in saying they were men who were entirely unfit to enter the medical profession.

Dr. Semple: Many (students) consider it (the London Apothecaries' examination) too severe. There are men who regard chemistry as a kind of *pons asinorum*, and avoid it by all means in their power; but some of those men go to the College of Physicians of Edinburgh, and get over the chemistry somehow or other, or to the Faculty of Physicians and Surgeons of Glasgow.

Mr. Christopher Heath: Men who fail here (London) can go and get a diploma elsewhere. . . . Men who fail at the examination of the College of Surgeons can go and get a diploma elsewhere. They generally go to Glasgow by preference, and sometimes to Edinburgh. . . . The double licence of the College of Physicians and College of Surgeons at Glasgow is considered the easiest, and next to that is the double licence of Edinburgh. As regards the Glasgow Faculty, I only judge by the results. I know that men who go up, who failed here, come back with diplomas.

Mr. C. MacNamara: If men fail here in one examination, they pass to another and less stringent examination in some other part of the country.

Mr. H. Morris: I remember many instances of persons who could not pass the examinations here, and who went to Scotland or to Ireland; but some of the instances have not been altogether on account of the difference in the severity of the examinations of the different bodies, but for other reasons.

Mr. Thos. Cooke: I have known a great many who, having failed in London, have gone to Scotland and passed. There are a great number who do that.

I omit my own evidence to the same effect, but refer to a tabular statement (page 69) submitted by me to the Commission, which puts beyond dispute that of 2,630 qualifications granted to Irish students in 10 years (1865-74), 491 were granted in Scotland. I also refer to an analysis of the published pass lists of the Edinburgh Colleges for one year, from which it appears that, of 277 students passed, only 35 were Scotch educated, the remaining 242 being English, Irish, and chiefly Canadian.

I have found it necessary to quote these proofs in vindication of ungentlemanlike aspersions upon my truthfulness, but I regret to have to do so at this time. I think it right to express my belief that the Scotch Colleges have improved their examinations, and are willing that this condition of things shall be a "bygone," if the Medical Bill should pass, and I think that, this being so, these Colleges are entitled to a larger representation on the local Medical Board than the Bill gives them.

All other of my statements made to the Fellows of my College I am equally prepared to prove by indisputable documentary evidence.

I am, Sir, yours, &c.,

ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.L

Obituary.

DR. C. H. DIXON.

ONE of the episodes of the English military occupation of Egypt which most nearly touched the feeling of the medical officers on service there was the untimely death of Dr. Charles Hampden Dixon, who was killed by a fall from his horse, leaving behind him the universal regrets of his brother officers, combatant and non-combatant. Dr. Dixon was the son of the Rev. Robert Vickers Dixon, sometimes

Fellow of Trinity College, and now Archdeacon of Armagh, and during his studies in the Medical School of the University of Dublin he took high rank by his industry and intelligence. Having obtained the M.B. and B.Ch. in 1880, he passed at once into the Army Medical Department, and in the beginning of the Egyptian campaign took charge at Cairo. There his unwearied and conscientious performance of his duties, as well as his many attractive social qualities, gained for him the respect of his superiors, the warm friendship of his fellow-officers, and, it may be said, the love of the sick of whom he had charge. Shortly before his death he suffered from a serious attack of illness, and it was, we believe, in some measure from the weakness which resulted that the melancholy accident happened which caused his death. His funeral was an occasion of almost public mourning in Cairo, for it was attended not only by his medical brethren, but by every officer up to the General Commanding who could be spared from duty, and the warmth of affection with which he was regarded was manifested by the erection of a marble Celtic cross to his memory by his brothers.

The following is an extract from a letter subsequently written by General Stephenson, commanding the forces in Egypt, to Dr. Dixon's relatives:—

"I had special opportunities of judging of your son's good disposition as well as of his professional merits, in consequence of his being entrusted with the medical charge of the headquarter staff. His genial, pleasant manners made him a great favourite with us; his attention to his duties was untiring, especially during the trying time of the cholera epidemic, when his devotion to his patients was deserving of all praise. A high opinion was entertained of his professional abilities, and the universal feeling of regret at his premature death, which was marked by the attendance at his funeral of every available officer in the garrison, a feeling which I have never known surpassed, is a higher tribute than any which I can pay him to the respect and regard which all of us entertained towards him."

Literature.

BRAY'S SCIENCE OF MAN. (a)

MR. CHARLES BRAY is one of that small body of men who deserve to be classed as "acute" thinkers. He is known to many readers through "The Philosophy of Necessity," a work which has afforded suggestion to a considerably larger number of writers and thinkers than have cared or remembered to acknowledge the source of their inspiration; and his freshness of style and close intellectual grasp of difficult problems have been the means of opening up to others than himself a realm of speculative thought, the cultivation of which has served to enrich modern literature with much that is valuable and permanently good in itself. In "The Science of Man," Mr. Bray discusses his subject from a philosophical standpoint purely, although the first two chapters of the book are so far materially scientific that they include a physical and morphological disquisition on the telluric conditions surrounding the individual and influencing his development. Next "mortality" is considered; and this section is written in the author's happiest style. It will serve to convey an admirable conception of the originality of his labours; and though the conclusions arrived at may fail to find acceptance, nothing can be urged against the innate cleverness that pervades the reasoning and the exposition embodied in the section. "Physics and Metaphysics," "Religion and Sociology," are subjects of succeeding chapters, the work being concluded by a summary of the whole argument.

Mr. Bray has opinions of his own on the subject of Man, and opinions which do not necessarily fit exactly in agreement with those held by the foremost apostles of the scientific creed. He bases future advance on a quantitative increase of the nervous system of man, and will not accept utilitarianism in its full completeness; but in all his work there is a tacit admission, sometimes too forcibly expressed, that individual rectitude and individual happiness must be conjoined in a perfect society. Though outside the strictly technical field of a medical man's reading, "The Science of Man" is a book that it will be good for medical men to read.

(a) "The Science of Man: a Manual of Anthropology, based on Modern Research." By Charles Bray. London: Longmans & Co.

It is impossible that its perusal shall do less than stimulate a happy reflection; and it may become a profitable study, as it certainly will prove to be pleasurable. We cordially recommend it to all who can feel an interest in healthy speculation and sound philosophy.

THE ORGANS OF SPEECH AND THEIR APPLICATION IN THE FORMATION OF ARTICULATE SOUNDS. (a)

THIS book is one of the International Scientific Series, and brought out in the same style as its predecessors. The subject is discussed with special reference to the requirements of philologists, so that the author has departed a good deal from the usual method of arranging sounds in physiological works. He has constructed, as we believe, a system in which all known articulate sounds find a place, and, indeed, all with which we may hereafter become acquainted. Such a work must interest both philologists and musicians, as well as anatomists and medical men. Indeed, everyone of a liberal education might be pleased to dip into it; and the woodcuts will be of considerable assistance to the general reader in enabling him to follow the author through his technical statements. We would specially commend the account of the production of vowel sounds, and the engravings by which this is very clearly illustrated.

ROBERTS' MEDICINE. (b)

DR. ROBERTS' handbook of medicine is too well known and appreciated for any lengthy notice of a new edition of the work to be necessary. Certain changes effected in it, however, demand attention, chief among which is the return to the one-volume form of publication originally adopted by the author. Whether this is an improvement on the dual shape observed with the three editions preceding, must be determined by the success achieved by it; but for ourselves we confess to entertaining a preference for the two volumes, as being more conducive to comfort in reading.

The work has been very carefully revised throughout, and in many parts, especially that treating on diseases of the nervous system, it has been re-written, to be in conformity with latest advances. The arrangement of the articles remains as heretofore, the distinctive features of the book being preserved, so that it will retain the characteristics which have won for it so large a share of favour as a student's manual. It is an undeniably good text-book, and well deserves the popularity it enjoys.

Pass Lists.

Army Medical Service.—The following is a list of candidates who were successful for appointments as surgeons in Her Majesty's British Medical Service at the competitive examination in London on February 4th, 1884:—

	Marks.		Marks.
1 Barefoot, J. R. ..	2440	11 Doyle, J. J. F. ..	2145
2 Clement, R. H. ..	2420	12 Manders, N. ..	220
3 Hunter, G. D. ..	2335	13 Colledge, L. R. ..	2100
4 Beever, W. C. ..	2300	14 Freyer, S. F. ..	2075
5 Anderson, L. E. ..	2275	15 Birt, C. ..	2070
6 Russell, G. B. ..	2250	16 Henderson, R. S. F. ..	2020
7 Spence, A. E. C. ..	2220	17 Mitchell, H. ..	2000
8 Mallins, J. R. ..	2200	18 Butterworth, S. ..	1990
9 McCormack, R. J. ..	2180	19 Holmes, C. J. ..	1930
10 Thompson, H. N. ..	2169	20 Lane, J. R. ..	1920

Naval Medical Service.—At the competition for commissions in the Medical Service of the Royal Navy, held on the 4th February and following days, in the Hall of the University of London, Burlington Gardens, the undermentioned gentlemen were the successful candidates:—

	Marks.		Marks.
1 Puddicombe, F. M. ..	2425	7 Smith, J. L. ..	2140
2 Gunn, D. S. ..	2230	8 Thomas, J. H. ..	2130
3 Gordon, H. J. ..	2220	9 Lilly, F. J. ..	2120
4 Harries, H. ..	2200	10 Dowson, J. ..	2070
5 Corcoran, E. ..	2145	11 Dean, G. F. ..	2035
6 Thomas, J. Lloyd ..	2145	12 Welch, G. ..	2060
		13 Iliewicz, H. F. ..	2030

(a) "The Organs of Speech and their Application in the Formation of Articulate Sounds." By George Hermann von Meyer, Professor of Anatomy, Zurich. London: Kegan, Paul, Trench & Co. 1833.

Notices to Correspondents.

✂ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

WHAT COOKS DIE OF.

THE special affections of professional cooks, says the *Sanitary Engineer* in its last issue, are firstly, those due to alcoholism, then anæmia, phthisis, rheumatism, dyspepsia, diseases of the liver, and certain diseases of the skin. Consumption is not infrequently found amongst cooks, for two reasons, first, the impure air which is breathed, and second, the constant variation of temperature to which they are exposed. These same causes also produce rheumatism, which, in many cases, is distinctly due to the unsanitary state of the kitchens. Varicose veins due to prolonged standing, and hernias caused by lifting heavy weights, are frequent among cooks. Much might be done to improve their health by providing well ventilated and lighted kitchens, but the chief source of their ailments is one which they themselves must control, viz., the excessive use of wines, beer, and alcoholic liquors of all kinds.

MR. F. P. H. is thanked for the information, which he will find referred to in another column.

DR. J. S. (Liverpool).—You may safely prescribe the preparation; it is not a patent nostrum, albeit proprietary; its composition is known, and we have personally seen excellent effects from its administration.

OATMEAL PORRIDGE.

WE cordially endorse the opinion of the *Medical Times*, which asks: Why is it that that most economical and nourishing of all foods—*oatmeal porridge served with milk*—finds, in spite of all that medical precept can teach, and medical example endorse, so few advocates in this country? Children who have been brought up to make it their daily breakfast take to it naturally and easily, and thrive under its use. No hard-working adult who has proved its powers of support through a long morning of cold, exposure, and hard exercise, will allow that any other kind of food is so sustaining and so easily assimilated. Yet how rarely does it form a feature of our national breakfast table! This is chiefly, we believe, because few know how it should be prepared, in its perfection, so as to be both attractive and digestible.

AN AUTHOR.—Your book was duly received and acknowledged in these columns some months since. A lengthened criticism has more-over been written, and now awaits the exigencies of space.

AN AGGRIEVED PRACTITIONER.—A patient has a perfect right to dismiss you and call in another practitioner, or his friends may do so, and you have no legal remedy; but you can have no cause for grievance against your brother practitioner, who will probably be treated in the same uncerimonious fashion as yourself.

THE OLDER ELECTRICITY.

"PROFESSOR TYNDALL will begin a course of six lectures at the Royal Institution, On the Older Electricity: its Phenomena and Investigations, on Thursday week (February 28), illustrated by experiments. Professor Hughes will give a discourse on Friday evening, next, On Theory of Magnetism, illustrated by experiments.

N. E. R.—It is scarcely a subject that comes within the range of medical journalism to hazard an opinion upon. Our correspondent should attend the Course of Lectures at the London College of Surgeons, which commences on Monday next, when, perhaps, Prof. Flower will enlighten him as to the classification of the races of the human species.

DR. WHISTLER.—With pleasure, in an early number.

MR. L. J. M.—The person named does not appear in the official Register, or in this year's Medical Directory; beside which, we have reason to know the man to be a quack.

MR. ROBERT JOHNSON.—There was a full discussion of this question in these columns some five years since; you had better apply to the publisher. Your query is not one that can be answered in a notice to an unknown correspondent.

Meetings of the Societies.

WEDNESDAY, FEBRUARY 20TH.

BROMPTON HOSPITAL FOR CONSUMPTION.—At 4 p.m., Dr. R. Douglas Powell, On Emphysema.

THURSDAY, FEBRUARY 21ST.

HARVEIAN SOCIETY.—At 8.30 p.m., Dr. W. H. Day, On a Case of Scarlet Fever in a Boy, followed by Nephritis, Convulsions and Death; Temporary Relief by Wet Packing.—Dr. Broadbent, On Prognosis in Structural Diseases of the Heart.

FRIDAY, FEBRUARY 22ND.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Parker, On Mammalian Descent.

ROYAL INSTITUTION.—At 8 p.m., Sir F. Bramwell, On London (below bridge) North and South Communication.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Mr. Mansell Moullin, On a Case of Thrombosis of the Vena Cava.—Mr. E. Clement Lucas, On a Case of Charcot's Joint Disease.—Mr. Noble Smith, On a Case of Dislocation of one of the Semilunar Cartilages.—Dr. Samuel West, On a Case of Multiple Hepatic Abscesses in a Boy.—The following living specimens will be exhibited:—A Case of Excision of the Patella, by Mr. E. Clement Lucas; Anomalous Affection of certain Bones and Joints, by Mr. W. Marrant Baker; A Case of Nodules on the Finger, by Mr. Godlee; Case of Pulmonary Regurgitation, by Dr. J. Kingston Fowler.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY—Hospital for Women, 2 p.m.—Metropolitan Free, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Orthopedic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 2 p.m.

TUESDAY—Cancer Hospital, Brompton, 3 p.m.—Guy's, 1.30 p.m.—St. Mark's, 9 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 2 p.m.—West London, 8 p.m.

WEDNESDAY—Great Northern, 2 p.m.—London, 2 p.m.—Middler, 1 p.m.—National Orthopedic, 10 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Mary's, 1.30 p.m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.

THURSDAY—Central London Ophthalmic, 1 p.m.—Charing Cross, 2 p.m.—Hospital for Diseases of the Throat, 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London, 2.30 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.

FRIDAY—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—King's College, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal South London Ophthalmic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.

SATURDAY—King's College, 1 p.m.—London, 2 p.m.—Royal Free, 9 a.m. and 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

Vacancies.

Armagh Union, Richhill Dispensary.—Medical Officer. Salary, £140. Election, February 25. (See advt.)

Birmingham General Hospital.—Resident Medical Officer. Salary, £180, with board and residence. Applications to the House Governor by February 28.

Chesterfield Union.—Medical Officer for the Bolsover District. Salary and fees about £48 per annum. Applications to the Clerk by February 23.

Coombe Hospital, Dublin.—Assistant to Master. Applications to Master, or at Coombe Hospital.

Fulham Union, London.—Resident Medical Superintendent. Salary, £350. Applications (printed forms will be furnished) to be made by February 25, to the Clerk, Board Room, Hammermith.

Kent Hospital.—Physician on the Staff. Applications to the Secretary at the Hospital, Canterbury, by March 22.

Oxford, Radcliffe Infirmary.—Dispenser, non-resident. Salary, £100. Applications to the Secretary before February 27.

Royal Free Hospital, London.—Resident Medical Officer. Salary, £104, with board. Applications to the Secretary before Feb. 2. (See advt.)

Appointments.

GRAY, E. B., M.D. Oxon., M.R.C.S., Consulting Physician to the Radcliffe Infirmary, on resignation of the office of Physician.

GRIFFITH, W. S. A., F.R.C.S., M.R.C.P. Lond., Physician to Out-patients at the Samaritan Free Hospital.

GRINDON, F. J., M.R.C.S., Medical Officer and Public Vaccinator to the Olney District, Newport Pagnell Union.

GROOM, W., jun., M.R.C.S., Medical Officer to the Tenth B. District of the Wisbech Union.

LANE, W. A., M.S., F.R.C.S., Assistant Surgeon to the Hospital for Sick Children, Great Ormond Street.

ROBERTS, J. F., L.R.C.P., L.R.C.S. Ed., Medical Officer to the Ravens-stonedale District of the East Ward Union.

SAITHE, B. T., M.A. & M.B. Camb., House Surgeon to the Seamen's Hospital, Greenwich.

Births.

OWEN.—February 10, at Kent Lodge, Southsea, the wife of A. Lloyd Owen, M.D. Dub., of a son.

Marriages.

GAITSKELL-SMART.—February 12, at St. Andrew's, Fulham, Lieut. Walter J. Gaitskell, R.M., to Emily Caroline, eldest daughter of Sir William Smart, K.C.B., R.N., Honorary Physician to the Queen.

ROBERTSON-ROCHFORD.—February 14, at St. James's, Piccadilly, C. A. Lockhart Robertson, M.D. Cantab., F.R.C.P., to Mabel, only daughter of the late Colonel Rochford, Madras Army, and step-daughter of G. W. Turnbull, M.D., Exmouth.

SAUL-BROWN.—February 12, at St. John's Episcopal Church, Dumfries, Wm. Saul, M.D. of Bedford Square, London, to Mary, third surviving daughter of the late William Brown, ninth Baronet of Colstoun.

Deaths.

BEALES.—February 8, at his residence, Chapel House, Congleton, Cheshire, Robert Beales, M.D., J.P., aged 59.

MACKINNON.—February 12, at Campbelltown, Mary Stuart Mackenzie, widow of Dr. Campbell Mackinnon, C.B., Inspector General of Hospitals and Honorary Physician to the Queen.

BOY.—January 17, at Humansdorp, South Africa, John James Roy, M.R.C.S., only son of the late D. T. Roy, M.D., of Hammermith, aged 36.

Original Communications.

ON DISEASE OF THE SHOULDER-JOINT.

By FREDERICK JAMES GANT, F.R.C.S.,
Senior Surgeon to the Royal Free Hospital.

THE shoulder-joint is rarely the seat of disease, and few cases are recorded. Omitting rare instances of morbid growths in connection with the humero-scapular articulation, and speaking from a large experience with regard to inflammatory affections of other joints, I have met with disease of the shoulder-joint in the form of caries, very seldom, and as synovitis occasionally. Of chronic rheumatic arthritis or synovitis I now and then see a case; and I have known acute synovitis of traumatic origin, proceed rapidly, within forty-eight hours, to suppuration and destruction of the joint; or again, abscess has formed in the course of six months, giving a chronic character to the disease. But the following case is perhaps unique. The synovitis was apparently of rheumatic origin, yet it proceeded slowly to suppuration, and with the formation of a very large chronic abscess, in, and around the joint; and the extra-articular portion being bilocular, lying partly under the deltoid muscle and in the axilla, and partly in the supra-scapular fossa. This suppurative synovitis resulted in complete destruction of the articular surfaces, leaving the capsule entire except an opening on the inner side, which communicated with the external abscess.

The particulars relating to the clinical history and characters of this disease are also worthy of notice. A man, æt. 43, whose father had suffered much from rheumatism, had himself experienced rheumatic pains, chiefly in the hips, loins, and back, never in the knees or ankles. A year ago he was laid up with such an attack, which lasted four months. He had never been quite free from pain since in the parts affected, and dates his present illness from that attack. At the end of nine months he first felt pains in the right shoulder, with a return of pain in the hips; this attack having

come on after straining efforts in using a chopper, which was his customary work. The shoulder pain gradually became more severe, and a month after its accession, a diffused swelling appeared all around the joint, giving some relief. Having suffered more or less in this state for two months longer, the man came under my care, in the Royal Free Hospital, November 30, 1881. The joint was then acutely painful, especially in the motion of abducting the arm, and this movement was attended with a dry creaking sound. The shoulder appeared double the size of that on the other side, owing to a considerable fulness of the deltoid muscle, and this swelling had a semi-fluid consistence, as felt through the substance of the muscle, beneath which it evidently lay. The contour of the shoulder gradually enlarged, and then a second, softer swelling appeared in the supra-scapular fossa, which seemed distinct from the former around the joint, the indistinct fluctuation of the one swelling not apparently communicating with the other. I often tried to determine this question, not only by palpation, but also by putting the joint through its various movements, but whatever altered relation the peri-articular enlargement could thus be made to assume, the supra-scapular swelling remained unaffected, whether in point of size, tension, or the transmission of any fluctuation. At length the swelling beneath the deltoid extended downwards into the axilla, and somewhat forward to about one inch under the clavicle. The whole appearance, so far as it could be included in one aspect, is represented on next page. Starting pains now occurred at night, and when the man attempted to raise the arm he felt a "clic" in the joint. The general health remained undisturbed by pyrexia; but marked albuminuria made me unwilling to subject the joint condition to any operative interference. Aspiration was resorted to, partly with the view of determining the diagnosis as to the presence of a large chronic abscess, or a soft fast-growing sarcoma. The supra-clavicular swelling was first appealed to; it yielded a fluid too thick to pass through a large-sized aspirating needle. About a drachm having been withdrawn, it was found to consist of pus, with a large

admixture of fatty cells. Aspiration of the axillary portion of the joint swelling gave issue to a similar fluid. Another attack of severe pains in nearly all the joints was followed by a notable enlargement of the shoulder. But the proportion of albumen in the urine diminished from a fourth to one-eighth, the specific gravity remaining at the same point, 1005, and the reaction acid. The general rheumatic attack seemed, however, to concentrate at length in the right hip.

which became exceedingly painful, with some swelling round the great trochanter.

Choosing the best opportunity for operation, I opened the axillary tumour by incision; only a small quantity of pus escaped, and then a drainage tube was inserted. My usual dressing, dry lint and tenax was applied. The discharge from the axilla continued, and certainly brought relief. But the shoulder remained full and tense. It was, therefore, deemed desirable to repeat the operation over the joint. A longitudinal incision, from the acromion downwards, to the extent of four inches, gave free and dependent exit to a quantity of sanious pus, and allowed also of the introduction of the finger, so as to explore in all directions. The swelling around the joint evidently did not communicate with the supra-scapular swelling, the abscess was bilocular. The capsule of the joint was found to be entire, except a small opening on the inner side; and as the articular movements were perfect, and without any grating sensation, the articular surfaces were unaffected at this period of the case. A second incision was made in the supra-scapular swelling, and that cavity emptied. A drainage tube inserted into either cavity, that around the joint, and that which lay above the scapula, provided a free exit for any discharge from both. A third drainage tube in the previous axillary opening prevented any bagging in that direction. The wounds were otherwise closed, united with silver wire, and dressed with dry lint and tenax pads.

These procedures proved to be very salutary. The discharge continued, but of a fairly healthy character, and daily diminishing in quantity. On the sixth day very little was found on the dressings. The temperature, which before opening the abscess, had been 101.2, fell to 99. The general health rallied, the patient feeling stronger and taking more nourishment. But after a few days further improvement, albuminuria prevailed to an overwhelming degree, and the man daily succumbed.

Post-mortem examination revealed nothing beyond the usual appearances of old standing disease of the kidneys, and concomitant changes in other organs. The shoulder-joint had undergone complete destruction of the articular cartilages, exposing two or three patches of caries on the head of the humerus, and the glenoid cavity being also completely denuded. The capsular ligament remained entire, except on the inner side, a small opening there communicating with the large extra-articular bilocular abscess.

The whole case is anomalous and instructive in its exceptional character among diseases of the joints.

GANGRENE (a)

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S.,

Emeritus Professor of Clinical Surgery at the London Hospital.
Consulting Surgeon to the London Hospital, and to the Royal London Ophthalmic Hospital.

MR. HUTCHINSON commenced his clinical lecture on Gangrene by narrating the histories of a number of illustrative cases, as follows:—

CASE I.—An elderly gentleman, residing at Reading, when on his way to church, slipped, and fell to the ground, and sustained a compound fracture of the thumb of one hand. The wound subsequently became gangrenous, and during the patient's illness a rash made its appearance on his body, the gangrene at the same time spreading, and ultimately causing death. Mr. Hutchinson was not consulted until after the fatal issue of the case, when it was contended on behalf of an insurance company that death was due to scarlet fever, the rash observed ante-mortem being appealed to as evidence of the fact. This, however, was, in Mr. Hutchinson's opinion, undoubtedly caused by the septicæmia set up by contamination of the blood by the gangrene, which was of the spreading kind, and to the effects of which, and the accident which originated it, the death of the patient was attributable.

CASE II.—In this case the subject was a surgeon and a friend of Mr. Hutchinson's, who, while performing an operation on a diseased hip-joint, scratched one of his fingers, the injury at the time being regarded as one of very slight character. The next night, however, intense pain was experienced in the injured finger, followed by inflammation, which rapidly increased in severity until, four or five days after the accident, the whole finger had assumed a gangrenous condition. The patient was a man in the enjoyment of excellent health, without any evidence of arterial disease, and amputation of the affected finger was resolved upon and performed, the absence of any disease above the seat of gangrene being first clearly established. This occurred ten or twelve years ago, and the patient has been well ever since, the wound having healed up quickly and perfectly. In this case a very trifling initial wound sufficed to set up changes resulting in gangrene of the tissues, and the supposition at once presented itself that an introduction of poisonous material from the diseased joint on which the gentleman was operating when his finger was scratched, this being, in the lecturer's opinion, a reasonable explanation of the circumstances.

CASE III.—A young woman, in good health, by trade a sempstress, pricked her finger with a clean needle while sewing, and the injury was succeeded by inflammation of the finger, passing on to gangrene, and necessitating the eventual amputation of the digit. The stump healed without difficulty, and no bad symptoms marked the progress of recovery after the operation. In this instance no explanation of the gangrene is afforded by the immediate circumstances of the case.

CASE IV.—A lad, æt. 18, was admitted into the London Hospital about twelve months ago for gangrene

(a) Abstract of a Lecture delivered on Wednesday, Feb. 13th, at the London Hospital.

of the hand. He had been a butler in the country, and placed amid surroundings very favourable to good health, and seemed to be in the enjoyment of it. He was of florid complexion, temperate in habits, well nourished, and well cared for in all respects. He accidentally pricked one of his fingers, and soon afterwards, during cold weather, but not intensely so, he carried a luncheon basket out to his master who was shooting. While so engaged the injured finger was exposed to the cold, and this so affected it that it speedily inflamed and became black and gangrenous. The gangrene, however, was not of the spreading kind, and was limited above by normal healthy tissues, and offering a favourable subject for amputation of the finger, this was performed.

This group of cases was interesting, said Mr. Hutchinson, from offering examples of the most varied circumstances under which one form of the disease he was discussing presented itself. The patients were of very different ages, and otherwise most unlike one another; and he adduced them in proof of the fact that it is in the power of inflammatory changes to induce a local gangrene in persons who are otherwise in a quite healthy state, and who may recover from the affection and once more return to a permanently healthy condition. Such instances could only be regarded in the light of accidents.

As examples of a different class of cases, the following were next recorded:—

CASE V.—About two or three years ago, a man was admitted into the London Hospital with the ends of all his fingers gangrenous at the tips, the rest of the digits being in a red and swollen condition. The patient had always possessed a feeble circulation and had throughout life been constantly subject to chilblains. One night, through the occurrence of a railway accident, he had been compelled to spend many hours in working under exposure to the cold, and during this time he had to handle a quantity of iron. He did not suffer from frost-bite in any way, the degree of cold not being sufficiently intense to produce it; but notwithstanding, he was attacked with inflammation of the fingers, which passed on into the gangrenous state observed on his admission into hospital.

CASE VI.—A little girl, *æt.* 12, came under Mr. Hutchinson's care with her right arm, from the elbow down, dusky, livid, and seemingly on the point of becoming gangrenous. The other hand was slightly affected in the same way. This congestion had been induced as the result of long exposure to cold at a boarding school, where fires were not regularly maintained in the rooms inhabited by the pupils. The child was one of a family distinguished for its feebleness of circulation, and her system was consequently in a state to be readily depressed by exposure to a degree of cold which would in others of robust frames be unattended by any ill consequences, on which account the case excited a good deal of anxiety in those who had it in charge. It was even feared that some, at least, of the fingers of one hand would be ultimately lost by gangrene, but this catastrophe was averted by the treatment pursued. This consisted in wrapping the arm in cotton-wool, and keeping the patient in a room of a warm, even temperature, and later on slight friction of the hand and arm, followed by application of a bandage; recovery finally taking place.

It has long been known to comparative pathologists that cold exerts a definite influence on domestic animals submitted to it soon after birth; and one familiar fact in this connection is afforded by the condition of the tails of young pigs, which are occasionally absent in all the members of the same family. When this peculiarity is observed it may be taken as evidence that the animals were littered during the prevalence of cold weather, for it is only at such times that the loss referred to occurs; and then it is not an infrequent event. In the vegetable kingdom, also, a similar state

of things obtains, for we find that during frosts it is the extreme shoots and terminal buds of plants that become dry and shrivelled up, these parts being those farthest removed from the vital centres of the plant, and least subject to the preserving effects of the sap circulation.

In that form of gangrene of the extremities which assumes a symmetrical character and which is known as Raynaud's disease, the conditions obtaining in the affected individual are of the kind already referred to and illustrated above. The circulatory process is maintained in a feeble inefficient fashion, the constitution thereby suffering, and being less robust, while the arterial vessels very readily contract on exposure to cold, and do not, without much difficulty, recover their normal calibre. The case of the little school-girl already narrated affords an admirable example of this class of patients.

In some instances, however, the disease fails to follow the symmetrical distribution described by Raynaud, and regarded as a typical characteristic; and careful examination of these cases assists us to understand the causes which give rise to the symmetrical disease. Such an example was recently recorded at a meeting of the Clinical Society of London by Mr. A. Pearce Gould. (a) It was that of a young man in whom pressure on the subclavian artery had been set up by an exostosis developed on the first rib, and which irritation resulted in gangrene of the limb with obliteration of the arteries commencing at the finger tips and spreading gradually towards the axilla. At one time, was probably the bony mass near the shoulder was much bigger than when the patient came under treatment, and consequently the pressure it produced on the artery more considerable. The first stage of the affection was inflammation of the fingers with impeded circulation from pressure above, this last factor being absent in the cases hitherto recorded in the lecture, and leading to thrombosis or inflammation of the arteries, which gradually advanced up the limb until all but the axillary trunk failed to yield any evidence of pulsation. Explanation of the impossibility of recovery of the case is at once found in this character of the injury which occurred, and which is found in the worst cases of gangrene—that is, the plugging of peripheral vessels and extension of the process thence upwards into main trunks leading from the heart.

Frost-bite is that form of gangrene which results when the tissues are directly exposed to severe cold, without immediate restoration of circulation through the part. In such cases operative interference is not advisable because the condition of the structures surrounding the injury, as a rule, quickly reverts the normal; and it is not, therefore, a common occurrence for gangrene of this nature to spread indefinitely. Generally, within a few days the extent of the gangrene is well circumscribed, and if due provision be taken for protecting the limb sufficiently, only that portion of it will be lost which chanced to be the seat of primary injury, *i.e.*, the part most exposed at the time. Such injuries are not followed by septicæmia.

(To be continued.)

THE Fellows and Members of the Academy of Medicine of Ireland have agreed to entertain its President, Dr. Banks, at a dinner, which is to take place in the College of Physicians on the 6th of March next. The hon. secs. to the banquet are Drs. Kidd and Henry Kennedy, and we understand that a large number of the Fellows have already sent in their names.

(a) See *Medical Press*, Feb. 13.

Attention is drawn to these by loss of voice. Tubercle and perichondritis are rare, compared with the catarrhal form, and are never present without the catarrhal form.

As a very important point in diagnosing tubercular from syphilitic forms of laryngitis I would have you bear in mind that syphilis is confined to the larynx, but tubercle never, and consequently sputum is not thrown off in syphilis, unless there is ulceration, but is so invariably in tubercle.

In all cases of phthisis there is more or less tumefaction of the larynx, and since the mucous membrane is more loosely attached at the upper point of the larynx than at the lower, there is always a bulging at, and above, the level of the false cords. When the condition is severe enough to affect the voice, the hoarseness would be that of catarrh with discoloration of the true cords. It is not uncommon for this condition to attract the attention of the patient before any signs of chest disease present themselves, and I have frequently been able to anticipate the diagnosis of consumption by the examination of the larynx.

The diagnosis of this disease is not very difficult. It is said by the patient to have commenced as a common cold with hoarseness of voice, cough, and the throwing off of sputum. Treatment which would be that of catarrhal laryngitis has but little effect upon it, though slight relief is obtained by staying in the house, and in an even temperature for a few days. The disease is very soon recognised as a chronic form. Now, among the chronic forms of laryngitis we have only syphilitic, tubercular, and a form of chronic laryngitis kept up by a persistent cause. If we can, by symptoms or their absence, exclude the syphilitic and the third form, we negatively prove the presence of the tubercular variety, and if, in addition, the tumefaction over the false cords is at all marked, the disease is almost positively proved. This form does not run on to ulceration without the development of tubercle in the mucous membrane. In such cases little points of tubercular matter may be seen in the membrane, and perhaps, also, in the epiglottis, which very soon become cast off, leaving small ulcerations behind.

It is not often that these ulcers become cured. I do not doubt that were the tubercular disease limited, the ulcers would heal, but I consider tubercular disease of the larynx incurable, inasmuch as it is a disease not confined to the larynx.

The third form of tubercular, or strumous laryngitis, if you look to our table of diseases, is that in which the cartilages necrose.

If you ask what treatment I advise in tubercular laryngitis, I can only say disregard the larynx and treat it entirely as a case of tubercular consumption.

(To be continued.)

NOTE ON THE USE OF APOMORPHIA IN INFANTILE CONVULSIONS.

By EDWARD COTTERELL, M.R.C.S.Eng., L.R.C.P.Lond.

On Nov. 11th, 1883, I received a summons requesting my immediate presence to a child in a fit. Upon my arrival I found the patient, a child, *æt.* 18 months, suffering from typical infantile convulsions. The mother stated that the child was attacked about half-an-hour after its dinner, which upon inquiry I found consisted principally of greens and potatoes. The attack was preceded by vomiting. There was great congestion of the veins of the neck, and the breathing was stertorous. I immediately proceeded to use artificial respiration by the Marshall Hall method, and after about five minutes the breathing became less stertorous, and the cyanosis less. I thought it would be a good plan to evacuate the contents of the stomach, in spite of the mother's assurance that the child had returned all its dinner, and, failing to produce reflex vomiting by irritation of the

fauces, I procured some apomorphia. I administered two minims of a two per cent. solution of this drug subcutaneously, and in one hundred seconds the stomach evacuated its contents—a prodigious quantity—with hardly any effort.

Immediately after this the convulsions ceased, and the child became quite conscious, nor has it subsequently had any attacks of a like nature.

I am not aware of apomorphia having been used before in the treatment of infantile convulsions, and my experience of this treatment up to the present rests upon this single case, but the result was so gratifying that I am persuaded to publish it, being confident that in apomorphia we have a drug capable of controlling the fits when these are due to gastric irritation; and I am sure that a very large percentage of infantile convulsions—at any rate, those occurring amongst the children of the poor—are due to injudicious feeding. Another recommendation in favour of the use of a hypodermic injection of apomorphia in this disease is the ease with which it can be administered.

Bicester.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Case of Acute Cerebral Meningitis.

Under the care of Dr. REGINALD SOUTHBY.

(We are indebted to Mr. ALBERT GRESSWELL, B.A. Oxon., M.R.C.S., for this Report.)

E. W., *æt.* 24, single, by occupation a cook, was admitted May 24, 1882, into Faith Ward, and died on the following day at 8 a.m. When first seen she lay on her back comatose, with the eyes closed and directed to her right. The pupils were equal, circular, and reacted to light. At intervals she moved different parts of her body and limbs. The arms and legs were natural. The pulse was 118, soft. The respirations, 30, were somewhat stertorous. The heart and lungs presented no abnormal signs. The abdomen was occupied by a prominent hard swelling in the hypogastric and left inguinal regions. On vaginal examination the os uteri was found to be directed forwards. Catheterisation did not effect any reduction of size of the swelling in the abdomen. The legs did not pit on pressure. The history as given by the relatives was as follows:—When three years old the patient had "low fever." When four and a-half she suffered greatly from vomiting for six months. About three years ago she fell from a third-floor window a distance of forty feet on to a stone pavement below, rending the skin of the forehead and crushing the left wrist and the right hand, and greatly bruising the skin of the left groin. She did not regain consciousness for a week, and is said to have had much discharge from her nose, but none from her ears. She recovered under Mr. Baker in this hospital, but had a very bad memory ever after this occurrence. She stayed at home for a year after leaving the hospital, and then, about two years ago, she resumed work as a cook and continued to enjoy fairly good health. She had, however, frequent fainting fits, in which she never completely lost her senses. A year ago she first told her friends that her stomach was painful. Has always been regular in the recurrence of the catamenia. Each monthly period since her fall has been attended by great pain in the left lumbar and left inguinal regions, and by severe pain during defecation and micturition. During the last six months the catamenia have been extremely painful, so much so that she has been unable to stand, and micturition and defecation have been exceptionally distressing. The doctor to whom she applied is said to have attributed these symptoms to inflammation of the womb, owing to too long standing at her work during the catamenial periods. Her last menstruation was about five days ago, and she was obliged then to give up work entirely and rest in bed for a day or two. Her present illness commenced apparently on May 22. In the morning she showed no signs of ill health, but towards evening she complained of "dreadful headache." At 1 a.m. on the 23rd she roused her sister, saying, "Do get up at once, as I feel that I am going mad."

Soon afterwards she became extremely sick, the vomit being like jelly and of a greenish colour. The sickness ceased about 8 p.m. the same day. Soon afterwards she raved and shouted, and frequently said that her head was on fire, and the friends were obliged to call in a policeman to keep her quiet. She has gradually been losing her senses from the first onset of the present attack, and has lain wholly unconscious, with twitchings of the muscles of the face, legs, and arms, since the morning of the 23rd. She has passed her water under her since the evening of the 22nd, but has had no motion since the 22nd. The urine drawn off by catheter on admission was acid, specific gravity 1030, and had about 5 per cent. of albumen, but no sugar. She lived only a few hours after admission. She was ordered—D. L. Beef tea, four eggs, and extra milk one pint. Also—

Pulv. jalapæ co., ʒss;
Mucilaginis, ʒj;
Ex aquâ, statim.

Her progress after admission is summed up in the note of the following day.

May 25th.—At 11.30 p.m. last night her temperature was 104°·6°. She was then sponged, after which the temperature fell to 103°·4°. At 2 a.m. this morning her breathing at times stopped, apparently for a few minutes at a time, and her temperature rose to 103°·8°. She was again sponged. Her pulse was extremely hypercrotic, varying from 140 to 160 per minute. Two drachms of pure ether were injected subcutaneously, and she was fed through a nose-catheter with milk, eggs, and brandy, ʒij. The respirations became more hurried (54 per minute), and also more markedly stertorous. The bowels were opened, and her water was passed freely under her. The pulse gradually became more rapid, and even still more soft, and she died at 8 a.m.

Post-mortem Examination by Dr. Moore, May 26th, 1882.

Body.—Has traces of a fracture of the left arm and fingers. Lean. No dropsy.

Head.—Calvaria, nil. Dura mater, nil. Brain: Beneath the pia mater the whole upper surface was smeared with purulent lymph, and there was a little on the base. None around the roots of the nerves or in the ventricles. The vessels of the whole brain were fuller than natural.

Chest.—Lungs: Some adhesions between the layers of the pleura; otherwise normal.

Heart.—Weight, 7½ oz. Valves nil.

Abdomen.—Liver, nil. Spleen soft and enlarged. Stomach and intestines, nil. Kidneys engorged. Capsule readily stripped off the surfaces, which are smooth. Pelves engorged, and containing large blood-clots. Ureter and bladder, nil.

Remarks.—This case presented many points of interest. The sudden accession of severe headache, the violent vomiting, the rapid intensification of the headache, the rapid onset of delirium and coma, the apparent interruption of the respiration, for a few minutes at a time, were among the chief symptoms which were suggestive of cerebral meningitis. Prior to hearing the history of the patient from the friends, the question as to whether the case might be one of diabetic coma presented itself, but on examination the urine was found to contain no sugar, and the account given showing that previously to May 22nd the patient was well in every respect, gave no support to this view. This patient presented no premonitory symptoms; on the contrary, the illness was ushered in suddenly by intense and persistent headache. In cases of tubercular meningitis, on the other hand, especially in children, premonitory symptoms are usually present. The age of the patient, which was 24, favoured also the diagnosis of simple cerebral meningitis, as opposed to tubercular meningitis; the lungs, moreover, presented no abnormal signs, as they often do in the latter disease. The short duration of this case, from the evening of May 22nd to 8 a.m. on the 25th, is noteworthy. The question in such a case, as to the cause of the attack, is full of interest. Was the attack here due to the fall 4½ years ago, or was it due to some other cause? Several similar cases have been recorded by Dr. Southey in the *Lancet*. In these cases Dr. Southey attributed the acute attacks of meningitis to the injury to the head received a considerable time previously. There was no trace of tubercle in any part of the body.

Among the fishes most commonly eaten, the cod is poorest in total solid matter, in albuminous compounds, and in fat.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND. PATHOLOGICAL SECTION.

A MEETING of the Pathological Section was held on Friday evening, Feb. 1st, at the Royal College of Surgeons, Dr. A. H. CORLEY, President of the Section, in the Chair.

Dr. E. H. BENNETT, Hon Sec., read the minutes of the previous meeting, which were confirmed.

SPONTANEOUS RUPTURE OF THE FEMORAL ARTERY.

The PRESIDENT detailed the history of a case in which rupture of the femoral artery had been the cause of death, and he exhibited the illustrative specimen. On the evening of Dec. 20th, 1883, A. B., æt. 56, a labourer, an inmate of the North Dublin Union Workhouse, was observed to be limping, and on being questioned complained of pain in the thigh, which was seen to be swollen. He was examined by Dr. R. Kenny the same evening, and rupture of the femoral artery was diagnosed; but the swelling had increased to such a degree, and the signs of collapse were so marked, that surgical interference was out of the question. There was no attempt at rallying, and he died next morning. A post-mortem examination was made under very unfavourable circumstances. All that could be done was to examine the limb and remove the diseased artery. There was enormous swelling, extending from Poupart's ligament to the knee, and obstruction to venous return had produced considerable oedema of the leg. A quantity of blood, partly fluid and partly coagulated, roughly estimated at nearly two quarts, was found diffused under the fascia lata. An examination of the artery showed a fusiform thickening of about three quarters of an inch in greatest diameter, and three inches long, extending from the apex of Scarpa's angle into Hunter's canal, and an opening somewhat funnel-shaped was seen in the anterior aspect of the vessel, the coats being unequally destroyed. The artery was pervious both above and below the rent, but for the whole extent of the dilatation was occupied by a soft reddened clot. On slitting up the vessel, it was perceived that there were three slight saccular dilations existing in the fusiform portion of the artery, and that it was the highest of those that gave way. Although the history was necessarily so meagre, it seemed evident that some obstruction to the current through the superficial femoral must have been of considerable duration, as the trunks of the profundus femoris and its branches were all considerably enlarged.

ELEPHANTIASIS OF THE SCROTUM.

The SECRETARY exhibited for Dr. W. H. HART, of Sierra Leone, an example of elephantiasis of the scrotum, removed by him from a Negro chief, æt. 56. In its shrunken condition, after preservation in strong spirit, the tumour weighed 14lbs. 5ozs.; weighed immediately after removal, it was 31lbs. The patient was in fair health, but affected by pityriasis. He had no fistula or urinary trouble, and had been tapped for hydrocele. On his admission no fluctuation could be detected in the tumour. He spoke no English, and his history was learned with difficulty. The tumour had been growing for ten years. His youngest son is 18 years old. He had come down from the country for operation, being willing to take any risk. On March 28th, 1883, Dr. Hart operated antiseptically, and with Esmarch's bandage. Both spermatic cords were ligatured, and lateral and a mesial flap saved. The testes were removed. Two veins were tied on removal of the Esmarch band. Considerable shock followed the operation, but the temperature on reaction rose only to 101°·2. On March 3rd the temperature, &c., were normal. On April 20th he was discharged with only a small portion of the surface of the penis being as yet uncicatrised. The examination of the tumour showed a vast hypertrophy of all the structures of the scrotum, amongst which the testes were, after a patient search, found, without serous envelope, the tunica vaginalis being obliterated, but the glands appeared healthy.

TWO CASES OF EPITHELIOMA FROM LOCAL IRRITATION.

Dr. BALL showed two specimens of epithelioma. The first was from the front of the scrotum of a man, æt. 40, who had worked as a distiller of crude carbolic acid from tar for nine years previous to admission to Sir P. Dun's Hospital. The

larger tumour was two inches long, and one and a-half inches broad, and beside it was a smaller wart, to which was adherent a well-marked horn. These growths were removed, and two years subsequently another small tumour was removed from the side of the scrotum. This was not connected with the cicatrix, and the author considered that it was attributable rather to a continuance of the original irritation than to an infection of the tissues by the previous growth. The glands in the groin, which were somewhat enlarged and hard before the first operation, had decreased markedly after the removal of the scrotal disease. A microscopic examination, which was made by Dr. Abraham, showed the appearances of ordinary epithelioma. Inquiries were made as to the health of the other operatives at the works where this man was employed. One man was seen with a large number of small epitheliomatous warts over the body, and Dr. Ball was informed that two men who recently worked there had horns, followed by open sores on the face, but he was unable to trace these cases. As only sixteen men were employed, it would appear that the fumes given off in the destructive distillation of tar produce an irritation peculiarly liable to originate epithelioma of a chronic form and in all respects similar to the chimney-sweep's cancer, as described by Pott. The second case was from the nose and upper lip of a man, *æt.* 49, who had suffered from lupus of the face and nose for many years. He had been under treatment by Dr. Walter Smith for lupus, and was transferred to Dr. Ball's care for removal of the tumour. There was a fungating mass of nearly black colour, and great vascularity involving the tip of the nose, the alae septum, and extending down into the upper lip. The sub-maxillary glands were not enlarged. The patient positively stated that this growth had only commenced three months previously. It was removed freely; but when the patient was seen three months after the operation a number of glands evidently carcinomatous were to be felt deep in the sub-maxillary space, the cicatrix appearing quite healthy. The intense malignity of this case formed a marked contrast with the former, and Dr. Ball suggested as an explanation of this fact the great vascularity of the tissues induced by the lupus before the commencement of the carcinoma. Dr. Abraham reported the case as distinctly one of epithelioma. In the deeper portions were to be found a very large number of small round cells, as usually found in lupus. The author alluded to a recent communication made to the Berlin Medical Society by Dr. Lewin, on "Carcinoma Developing on a Basis of Lupus," in which he reviewed the published cases of this condition stated to number about twenty.

NOTE ON TUMOUR OF THE NOSE.

Dr. ABRAHAM communicated a note on the tumour of the nose discussed by Dr. Ball. The deeper parts of the sections were chiefly made up of a more or less round-celled growth, much infiltrated with other small darkly-staining cells and nuclei. The texture was often loose and oedematous, and the lymph channels and spaces were well marked. Some of the latter contained finely granular and occasionally fibrous coagula. Protoplasmic masses were also to be sometimes found in various parts of the tissue. Towards the surface of the growth the larger cell-elements could be traced into prolongations from the epidermis, and in this situation numerous epithelial cell-nests were developed.

FRACTURE OF THE UPPER EXTREMITY OF THE HUMERUS.

Dr. E. H. BENNETT exhibited an example of fracture of the upper extremity of the humerus, which was, in his opinion, consecutive to dislocation. Having referred to his communication on this subject made at the Cambridge meeting of the British Medical Association, and to the paper by Mr. Eve, published in the *Medico-Chirurgical Transactions*, he expressed his opinion that this new example agreed with the five specimens already described by him in its general characters, the head of the bone being only slightly differently placed. It was united by ligament both to the scapula and to the humerus. It projected into the axilla, beneath the vessels, and had pierced the sub-scapular muscle at its lower border. It retained a great part of the sub-scapular attachment—*i.e.*, of the lesser tunicle of the humerus attached to it. The long head of the biceps was united to the bone in the fibrous tissue between the fragments. The specimen, unfortunately, was without life history.

The Section then adjourned.

SURGICAL SECTION.

At a meeting of the Surgical Section held in the Royal College of Surgeons, Mr. WHEELER, President, occupied the chair.

Mr. WILLIAM STOKES, Hon. Sec., read the minutes which were signed.

LIVING SPECIMENS.

The PRESIDENT.—A young girl, *æt.* 18, after removal of enormously hypertrophied breasts, the largest weighed 20lbs. 2. Excision of knee in a boy, *æt.* 11, for caries. 3. Child a year after harelip operation by exhibitor's method.

Mr. STOKES.—Case showing result of excision of the upper jaw for fibro-sarcomatous tumour, originating probably in the antrum.

Mr. LAMBERT H. ORMSBY.—Case of excision of knee-joint.

Dr. ARTHUR H. BENSON.—Primary lupus conjunctiva.

SPECIMENS EXHIBITED BY CARD.

The PRESIDENT.—Vesical calculi removed by lateral lithotomy.

Mr. STOKES.—1. Amputation at hip-joint, parts removed on account of a rapidly growing sarcomatous tumour on inside of thigh. 2. Cast of the thigh showing size and position of the tumour. 3. Multilocular ovarian cyst recently removed from a patient, *æt.* 17.

Mr. LAMBERT H. ORMSBY.—Amputation of the thigh (upper third) for large sarcomatous tumour of thigh.

Dr. J. HAWTREY BENSON.—Viscera of a woman who died of purpura hæmorrhagica.

THE RADICAL CURE OF HERNIA—THREE PAPERS.

Mr. WILLIAM STOKES, (Professor of Surgery, Royal College of Surgeons) read a paper on

THE RADICAL CURE OF HERNIA BY PERITONEAL AND INTER-COLUMNAR SUTURE.

Having alluded to the fact that the subject of the radical cure of hernia, had from remote antiquity to the present engaged attention, he mentioned, although it could not be said definitely, that the wished-for goal had been attained, still, thanks to Listerism, much had been gained. In proof of the fact that the feasibility of obtaining radical cures by operation, is a question *sub judice*, he referred to the writings of various eminent surgical authorities, some of whom are opposed to, and others in favour of, such attempts being made. The object of the various operations hitherto performed, viz., obliteration of the neck of the sac, with approximation and union of the tendinous structures about the hernial passages, also the methods of "dissection" were discussed. The author believed that the method recently adopted by himself and his colleagues, was simpler and more efficacious than any of those he mentioned. It consists in the insertion through the open neck of the sac and close up to the external abdominal ring of a deeply indented carbolised catgut suture or sutures according to the size, width, and depth of the neck, and this is followed by the approximation or closing of the canal and pillars of the ring, by the insertion of two or more sutures of a stronger or more durable material, such as chromicised catgut, gilt or silver wire. In fact, it was a dual system of suture, one being peritoneal and the other inter-columnar. Four cases were recorded in which this plan was adopted. In three of these successful results were obtained. The unsuccessful case was one of congenital inguino-scrotal hernia. The hernia reappeared three months after the operation. The failure was probably due to not having used a sufficiently durable material for closing the pillars of the ring, that which the author employed being chromicised catgut. In future he would employ in similar operations either carbolised silk or silver wire.

Mr. BARTON also read a paper on the radical cure of hernia. At the outset he laid down the principle of treatment, viz., that the internal ring should be so effectually closed as to prevent the hernia coming down into the canal at all. He described Wood's operation as a combination of this and of the old plan of invagination, which latter should be discarded, and the closure of the rings perfected. The direct operation was recommended, refreshing the edges of the ring as recommended by Gross, or cutting away the sac, as practised by Czerny. Three cases were related, 1, that of a boy *æt.* 3, who had a hernia as big as a cocoa-nut, and which could not be held up. 2. That of a young man who had been rejected at the physical examina-

tion at Sandhurst, for a small inguinal hernia. 3. A child three years old. In all three the internal ring was closed with silver wire, which was left in, but in the first case it had to be removed, subsequently, as the wound re-opened. The result was that in the first case the child left the hospital with a truss, but the hernia again came down. In the second case the result was satisfactory, and the gentleman was admitted to Sandhurst. In the third case the child was exhibited, but sufficient time had not elapsed to pronounce upon the result. The cases proved, first that the operation was readily performed, secondly, that (with antiseptic precautions) it was safe, and thirdly, that it was advisable, if not directly necessary to retain the wire sutures *in situ*.

Mr. KENDAL FRANKS read a paper on the

RADICAL CURE OF HERNIA BY THE METHOD OF DISSECTION.

This paper appeared in our issues for Jan. 23 and 30.

Mr. W. THORLEY STOKER said there were two distinct classes of cases, the class in which the operation was compulsory where strangulation existed, and the class where operation was a matter of election to promote the patient's convenience rather than to save his life. In nearly all cases of operation for femoral hernia, a permanent cure had been effected, but in large inguinal ruptures a radical cure was not so frequent, and in such cases the peritoneum should be sutured. In the second class of cases, he advocated Wood's operation. He did not think it mattered much whether the pillars of the ring were drawn together or not. A cure was effected by the inflammation exciting exudation of coagulum and lymph, which drew the parts together, thereby closing the opening as with a cork. He protested against leaving in the wire suture where the ring was sutured in inguinal hernia, as most unscientific and unsurgical-like, and a possible source of future trouble.

The PRESIDENT mentioned the result of nine cases in which he had operated by different methods. In a case of inguinal hernia on the left side, he exposed the neck of the sac, he then drew it down and applied a ligature, divided the neck and removed the sac below the ligature. This case was successful when seen two years afterwards. He performed a similar operation in the case of a female suffering from a small inguinal hernia in the centre and above Poupart's ligament, which became strangulated, and she was perfectly cured, having been seen five years afterwards. In a femoral hernia on the left side in a female, *æt.* 18, he opened the sac, pulled down, excised, and closed the edges, and the result eighteen months afterwards was most satisfactory. He adopted the dissection method in other cases, but without improving the hernia. In cases where the canal was greatly distended by a large hernia, it would be almost impossible to have a radical cure follow any radical measure, and the most likely was by excision of the sac.

Dr. MCARDLE observed that it was almost impossible to bring the edges sufficiently close together to keep behind the sac, and that the irritation of the veins was likely to produce phlebitis.

Having regard to the lateness of the hour, the further discussion was, on the motion of Mr. Ormsby, seconded by Dr. McArdle, adjourned to a special meeting.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

THE ADJOURNED DEBATE ON ALBUMINURIA.

This important debate was resumed on the 19th inst.

Dr. MACCALL ANDERSON Presided.

There was a good attendance of members of the profession, especially juniors.

Professor GAIRDNER opened the proceedings with a judiciously conceived address, in which difference of opinion from previous speakers was very notable. At the outset, Dr. Gairdner referred to Bright's opinions at considerable length, and then referred to Dr. Roberts' address on the first night of the debate. Dr. Gairdner differed from Dr. Roberts in believing that there is such a thing as normal or physiological albuminuria. He characterised the case mentioned by Dr. Roberts of cure of albuminuria, with hypertrophy of the left ventricle, as very unusual, though within the range of possibility. Dr. Gairdner inculcated the taking of a more hopeful prognosis in cases of albuminuria.

Dr. MORTIMER GRANVILLE restricted his remarks to "the

clinical significance of albuminuria," and amusingly ignored and flatly contradicted Dr. Gairdner's views. He dwelt on albuminuria as associated with nervous disturbances. He believed that albumen is always present in the urine; and directed special attention to two not generally recognised groups of albuminuria in which albumen occurred in the urine without renal organic change, viz., in young men in whom the genito-spinal centre had been debilitated and rendered preternaturally excitable, not necessarily by sexual excess, but by the struggle to repress and restrain the passions, a mental and nerve-centre excitement which might be so brought up as to prove as mischievous in its effects as excess or abuse. He said that these cases were frequent, and were often confounded with kidney disease as there were frequently pains in the region of the kidney. In the second class of cases to which he directed attention the patients suffered from mental depression or "nervousness," with perhaps "agoraphobia" or "claustrophobia," and were men of studious or sedentary habits at middle life. In these cases albumen was found in the urine, in some instances alternating with the presence of sugar. He held it unscientific and pernicious to regard these cases as due to renal origin. He denounced picric acid as an unreliable test.

Dr. MAHOMED read a lengthy paper which he, however, curtailed. In its entirety, the paper will doubtless be read with interest, but under the circumstances it appeared diffuse and disconnected. He criticised the theory propounded by Professor Hamilton that the increase of arterial pressure was due to the diminished specific gravity of the serum, and pointed out that the specific gravity of the serum was not usually decreased to any considerable extent in Bright's disease, quoting Quincke in support of this.

Dr. JAMES FINLAYSON also spoke.

The debate will be resumed on another night.

INCUBATION OF INFANTS.

THE results obtained by the aid of an incubator for rearing infants have just been published by M. Anvard, resident at the Maternity Hospital, in his *Archives de Tocologie*. The first incubator was used in Paris by M. Tarnier, and consists of a large wooden case divided into two portions, the lower of which contains warm water, while the infant is placed in the upper one.

Fig. 1.

At first the incubator was heated by means of a thermosyphon, but his system has been abandoned, fearing that through the negligence of the attendants the lamp would be left alight too long. The apparatus is now heated by filling the reservoir with boiling water both morning and evening, and thus a mean temperature of 80–82° C. is kept up. The child is clothed in the usual garments, because, if the skin was in contact with the air at a temperature of 32° C., it would lose some of its animal heat, and when taking out the infant to feed it, the danger of cold would be very great, were it unclothed. Among the different cases (151 in number) in which the incubator was used there were 98 infants which were born prematurely. Of these 81 died.

M. Anvard based his statistics on the weight of the children, and discovered that among those who weighed less than 2,000 grammes the death-rate was at the "Maternité," 66 per cent., at that of Paris, 65 per cent., while in those places where the incubator was used it was only 38 per cent. In the treatment of oedema, which is a serous infiltration of the tissues caused by the bad state of the infant when born, and the rigours of the exterior temperature, and in which as a rule 16 out of every 20 cases die, when the incubator was employed only 4 of the 25 placed in it failed to recover. It has been said that children brought up in this way die when exposed to the outer air, but such is not the case, as M. Anvard conclusively proves. It has also been stated that immature children placed in the incubator only live one or two months, viz., until the time arrives in which they ought to have come into the world; but this objection is not founded on any scientific basis, and is therefore not of any value. M. Winckel, of Dresden, has started a new theory of permanent baths, but we have not investigated it sufficiently to form any opinion. The accompanying cuts (Figs. 2. and 3.) show the new incubator brought

Fig. 2. Section of Incubator.

Fig. 3. Exterior of Incubator.

out by M. Anvard. In the lower part the stone bottles (Fig. 4.)

Fig. 4.

with filled hot water are placed, and the child is in the upper portion. They are replaced at the door O, which can be moved

to left or right. The air comes in at T, and passing over the water, becomes heated, and ascends through a wet sponge E. It goes out at A, where a little wind gauge is adapted to show the current. A thermometer is hung in the upper portion of the incubator. In the coldest weather, by changing the water every two hours, and putting the fresh in boiling, a temperature of 31° C. to 33° C. is kept up.

AIDS TO HYPODERMIC INJECTION.

WITHIN the past few years, medication by means of hypodermic injection has become much more general, and there are many circumstances in which this form of treatment is of signal value. In an especial manner does this obtain in cases of localised pain of a neuralgic nature, and where it is important to cause emesis when the patient is unable to swallow from disease or otherwise. While the first attempts at hypodermic injection date back to 1845 (it is even contended that they were employed in America in 1839), it is mainly to the late Dr. Andrew Wood, of Edinburgh, that their popularity has been due, and the agent chiefly employed has been some form of morphia. Since 1855, numerous other medicaments have been subcutaneously introduced into the system in certain cases with undoubted benefit.

Dealing in such cases with minute doses of strong alkaloids, it is of much consequence that the quantity thus employed be accurately gauged. The employment of ordinary solutions is not only troublesome, but without scrupulous care accurate dosage is difficult to ensure. In Wyeth's Tablets, now placed before the profession by Messrs. Burroughs & Wellcome, of London, these objections are satisfactorily obviated. The tablets, which are flattened convex discs, contain varying doses of the alkaloids or other active principles which it is desired to employ, combined with sufficient sulphate of soda to ensure consistency and to facilitate solution. These discs dissolve quickly in cold water; but warm water or gently heating by holding the spoon containing the fluid over a candle or spirit lamp ensures complete and speedier solution. For the sake of portability and general convenience, Messrs. Burroughs & Wellcome have just issued a neat pocket-case containing sixteen tubes filled with the most useful of Wyeth's tablets, an improved hypodermic syringe, and the requisite needles.

This case must prove a boon to active members of the profession, and will, we believe, become indispensable to the general practitioner's armamentaria. Of the alkaloid doses so contained we may mention sulphate of morphia, in $\frac{1}{4}$, $\frac{1}{2}$, and $\frac{3}{4}$ -grain doses, and we can personally testify to its efficacy; pilocarpine, in $\frac{1}{4}$ -grain doses, so valuable in causing diaphoresis and salivation; and atropia, in usual doses, which acts as a speedy antidote to the pilocarpine. Apomorphia is presented in 1-10-grain doses, a quantity sufficient to cause abundant vomiting in from three to four minutes—a property which can be taken advantage of in various forms of poisoning, pneumonia, tonsillitis, &c. Finally, we may mention aconitia, which, in 1-260-grain doses, affords marked relief in neuralgia. D. C. B.

THE Annual Metropolitan Dinner of the Irish Graduates' Association will be held at the Holborn Restaurant, on St. Patrick's Day, Prof. G. F. Yeo in the chair.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 27, 1884.

INDIVIDUALISM IN DISEASE.

MODERN conceptions of diseased conditions are in many respects of a different kind to those which were formulated at a time when the factors determining the onset and progress of illness were less definitely comprehended, and studied, than is the case in the present age. This difference needs to be carefully borne in mind, moreover, whenever an attempt is made to compare the state of knowledge possessed at successive periods in the history of medicine; and it would be manifestly unfair to charge to ignorance on the part of previous inquirers, the perpetration of errors against the commission of which we ourselves are protected, by reason of an increase in positive information at our disposal. Within recent years, too, there has been introduced an object of study to which the existing generation owes more than is perhaps generally understood; but the influence of which, great as it is in the present, is calculated to effect immeasurably larger advances in the future. It is difficult to assign an appropriate and sufficiently descriptive name to that of which we speak, but sooner or later some term indicative of it must be commonly adopted, and until a better has been suggested, it may be safe to use the word "individualism." The study of individualism as a factor in disease has for many of our ablest and most enthusiastic investigators an attraction which they find it impossible to resist; and to which, it must be added, they owe no small part of the success their labours have achieved. Slowly but surely the deeply suggestive meaning of diathesis, temperament, and idiosyncrasy

has forced its way to appreciation; and the crude ideas which formerly were entertained in this connection have yielded to clear and certain evidences of the intimate relations, subtle though they often, nay, nearly always, are, which exist between the two bodily states of health and non-health.

Innumerable records of cases could be quoted to prove that something above and beyond the visible signs of injury co-operate to determine the course it shall pursue in different subjects of the same disease. In one, it may be that a steady downward tendency to death will characterise the same affection which in another patient, situated possibly in close contiguity to the first, and submitted to exactly the same local surroundings, will pursue a course of comparative harmlessness, and leave the sufferer finally to enjoy a quick recovery. Possibly, also, both patients may at the outset have been in a condition of health in no wise inferior to that it had been usual for them to experience; and yet, as is well known in clinical work, the ultimate results of the illness will in the two cases be diametrically opposite. Whatever the causes leading to such diverse consequences are, they are intrinsically individual in their nature; and for an explanation of them we have to appeal to that factor in diagnosis to which we have referred under the title "individualism." It is in effect a compound of personal peculiarities, and includes, in addition to the specialities already named, those molecular and tissue characteristics that defy every attempt of the most perfect instruments of precision to elucidate their essential features.

It necessarily follows from this explanation that all attempt to unravel the mystery involved in this connection must be to a great degree purely speculative; and it is sometimes urged as a reproach against modern scientific medicine and surgery that this is a ruling defect in its method of research. But the charge is a most unmerited one in the face of all that has been accomplished hitherto; and it would be a grievous loss indeed should encouragement of the merely practical modes of advance lead to neglect of those which seem to lead to no immediate goal of finality. There are still encountered in the wards of hospitals and in private practice, a formidable array of diseases that too often prove intractable of cure, and that provoke the practitioner's despair. Not one of these but well deserves to be perpetually studied from every side, and under every auspice, until such time as means shall have been found to arrest the tribute of human life exacted as a consequence of the inability of science to combat their ravages. Not one of them, either, but is admittedly dependent in an infinite degree for its manifestations, on attributes of individualism which primarily determined its appearance in the subject of it rather than in any one of a hundred others similarly circumstanced. Cancer, rabies, phthisis, and tetanus may be taken as examples in point; and though the three first may justly be regarded as having greater dependence on structural properties of tissues, this, in the way that is of gross appearances, is inadmissible in respect of the last instanced, tetanus.

There are many facts connected with this affection that seem to surround it with a vague but terrible interest. It is an unmistakeable entity in clinical experience; it

cannot be confounded with anything else when once it has fairly established its hold upon its victim ; and in its acute form it offers the smallest chances of successful treatment. Its occasional occurrence in hospital practice is not unreasonably regarded with most anxious feelings by surgeons in charge ; and it is not a little peculiar that single cases are rare, although very long intervals may elapse between their appearance. Recently, a case occurred in the male accident ward of the London Hospital ; and within a few days a second case, being that of a woman in quite a different part of the building, terminated, like the first, fatally. It is not, of course, to be supposed that any direct connection between the two cases can be traced ; but it is quite possible to conceive that the individualism of these two patients predisposed them to react to whatever influences—climatic, atmospheric, telluric, or otherwise—combine to bring about changes that have for a result the production of tetanic convulsions.

The case of the man mentioned above possessed many points of interest in connection with the study of tetanus. He was but a little over twenty years old, and had been admitted after an accident through which the right hand had been crushed and lacerated, the thumb particularly being involved. The injury was not in any way one of excessive severity, and seemed to progress favourably ; but on the eighth day from the accident tetanic symptoms supervened, and death occurred within fourteen hours. In what way could the result have been brought about here, as in many similar cases ? We know that injury to nerves is usually regarded as the exciting cause ; but appreciable injury is by no means always present. Nor can this, of itself, be adduced as sufficient, for else we must look for tetanus as attendant on every wound in which nerve structures have been implicated ; whereas such consequences are, fortunately, rare exceptions. Irritation of nerves, whether direct or secondary to chemical changes of decomposition in the wound, is, however, an undoubted essential factor in the etiology of the disease ; and the transmission to, and possible exaltation of the irritation at, the reflex centres, constitute indispensable elements in it. Speedy removal of the local source of irritation, therefore, occasionally has checked the advance of the tetanus to uncontrollable stages ; but it is more than doubtful whether this plan of procedure is feasible in the majority of acute cases in which the course of the disease is rapid from the outset.

We have taken tetanus as an example of those diseases in consideration of which individualism must occupy an important place, because it is a typical instance of the class we are dealing with. It may very well be, however, that the principle we have endeavoured to enunciate must ultimately obtain a much broader application than even its advocates would elect to give it at present ; and that we shall be able to indicate the cause of every bodily affection with an exactitude in every particular case to which it now seems presumptuous to aspire. In surgery especially, is the field widest for its application ; for it is in the treatment of surgical diseases and injuries that the influences of individualism exert most marked differences of effect. What is required beyond all things is the power to recognise their presence by external signs before their

effects have been demonstrated by the progress of the case ; and especially do we look for and aim at, the acquisition of a power to direct, and if need be modify, the influences when they have been recognised. To this we would fain hope we are tending ; and every step that brings us nearer to such an end is one more triumph of science over disease, another trophy wrested from the hand of death.

ALCOHOLISM AND ITS REMEDY.

It is not such a great number of years since the first public outcry was heard against the abuse of alcoholic liquors, but since then it cannot be denied that great and important steps have been taken, and especially in one direction, towards remedying this great evil. The work has been carried on in the main by amateurs and quasi-scientists, and has principally consisted in a great and widespread endeavour to unite in large societies all such as shall promise to take a pledge not to use alcoholic liquors as a beverage. These gigantic strivings have been, however, materially aided by scientists, though these in their turn may have been pressed on to the work by the public outcry, who have satisfactorily shown that to persons in health alcohol in any ordinary and recognised shape or form is not a necessity. They have also shown that except in very small quantities the regular use of it is not only unnecessary, but harmful. With regard to this limited and very small quantity, however, the scientist and the average total abstainer are not at one. The scientist says that, in regard to this limited and very small quantity *per diem*, it is a matter of indifference whether a healthy adult takes it or not ; whilst the average total and aggressive abstainer says that alcohol is a poison that ought on all hands to be avoided.

Looking at our temperance and total abstinence societies, one would be tempted to say that an immense deal of good had already been done ; but looking, on the other hand, at our excise, revenue, and criminal returns, one would be almost tempted to despair of any good ever being or likely to be accomplished, so little influence has the great movement apparently had during the last half century in reducing the quantity of alcohol consumed per head of population and in improving criminal statistics. What is to be done to stem the torrent of drunkenness is still the great question of the day. Many people think that the present generation is past praying for ; that habits once formed will not be altered by much preaching and entreaty ; that the compulsory virtue that would be brought about by prohibition of the liquor traffic would be no virtue at all—it would simply be like the continence of the eunuch ; and that the only hope lies in healthy opinions and clear knowledge instilled into the minds of those whose habits are yet unformed—*i.e.*, the young.

Drunkenness appears to be the special vice of cold countries, and yet all cold countries have not a drunken population. Take Germany for instance. Continental winters are much colder than ours ; yet, notwithstanding their rigorous winters, Germans may be rightly called a sober people. A great deal of beer is drunk in

the German countries, and quite recently temperance societies have been formed there. They have, however, not owed their existence to attempts to put a stop to beer-drinking, but to curtail a spreading tendency to indulgence in schnapps or spirits. Beer drinkers are not supposed to require reformation, and it is only those who indulge in more potent beverages who are responsible for the introduction into Germany of the *Mäßigkeitsverein*, or Moderation Society.

For this class of dram drinkers, then, the temperance cause has been taken up in the Empire. There is one difference, however, between German and British temperance societies: the German article is a temperance or moderation society, whilst the British is in most cases a total abstinence society, and therefore in no sense but a nominal one a temperance society.

A German pastor named Georg Friedrich Fuchs has recently published a small *brochure* on "Alcoholism and its Remedy," that has been somewhat of a surprise to medical readers, for the reason that it does not discuss the subject so much from a theological as from a scientific and common-sense standpoint. Herr Fuchs has studied his subject long, and has made himself completely master of the literature of it. Going back to the year 1839 for his statistics, he depicts the effects of the abuse of alcohol on the person of the victim, upon his offspring, on the tendency to crime, and on the suicidal tendency in colours a little, perhaps, too lurid. This part of the subject is treated rather with the unconscious bias of the advocate than with the unprejudiced calmness of the judge. A man not trained in the study of general diseases must follow some medical guide or guides; his own limited knowledge of medicine will not always lead him to choose a safe one. He cannot check the teaching of another by his own observations, for he has not been trained to observe, so that the colouring of the picture he gives us is to some extent excusable.

On the other part of the subject, however—that treating of the remedy for the abuse of alcohol—his views will meet with the approbation of all who have studied the subject dispassionately. He does not demand that alcohol shall be absolutely banished—that its sale shall be prohibited. He does not recommend "local option," a measure which means that two men shall have the power of dictating to the third what he shall drink—a monstrous piece of legislation, if ever it come to pass. He places his hopes, not on one panacea, but on the dissemination of a healthy public opinion by means of moderation societies (*Mäßigkeits-vereine*)—not total abstinence societies; on the founding of asylums for drunkards, and on the establishment of people's coffee-taverns and wagons. We in Great Britain know that these coffee-taverns, when properly conducted, not only supply a great want, but may be made profitable to the shareholders. One such company known to us, taking in its numerous branch establishments about £1,000 weekly, has for years paid 10 per cent. He thinks, further, that alcoholic liquors should be highly taxed, although he acknowledges that this in itself is not sufficient to prevent the immoderate consumption of alcohol, and as proof of this he points to Sweden, where, notwithstanding high taxation, the

most rigorous conduct and supervision of the drink traffic, and notwithstanding all the repressive legislation against drunkenness that Sweden has seen fit to enact, the consumption of alcoholic liquors has again increased during the last few years. The Dutch laws, which prohibit the sale of spirituous liquors to youths under 16 years of age, he thinks worthy of consideration. We believe there is some such law in this country—a useful law, no doubt, but not nearly so much so as a more wide-reaching and practicable one in the same direction might be made to become. Who has seen children of tender years emerging from the public-house, bearing home the paternal or maternal beer, and has not been struck by the thought that legislation ought to step in and with a stern front forbid these infants to enter public-houses altogether unless accompanied by their proper guardians? Here is surely a blot. Let children be prohibited from entering these places, let publicans be prohibited from serving any one under 16 years of age with any intoxicating liquor whatever, and the legislature will do more at one stroke towards preventing the present familiarity of our youth, and in time of our adults, with these dangerous and demoralising places than all our local option dreamers will be able to accomplish in a lifetime. This legislation is practicable, and it would bear directly on those who are properly under tutors and governors, and not on grown men and women. In this country the law does not allow that drunkenness is any mitigation of the heinousness of crime. The German law on this point, in our author's opinion, should be altered, not in the direction of lengthening the punishment, but in that of sharpening it. He would order certain fast days, in which the only food of those in jail for drunkenness should be bread, and water the only drink, and this in the face of his acquaintance with the edict of George the 2nd of Hanover, of the year 1736, in which it was decreed that if a drunkard were not to some extent visibly improved in his vicious propensities after three days' incarceration on a bread-and-water diet, he should be held to be a criminal and punished accordingly. His proposal to limit the number of licensed houses to one in all villages of less than 1,500 inhabitants, with an additional licence for each additional 1,000 of population, would, in our opinion, benefit the holders of such licences as were granted much more than the cause of temperance.

THE IRISH CONJOINT EXAMINATION.

WE learn that the Irish College of Physicians has peremptorily, and without entering on the other propositions submitted by the College of Surgeons, rejected the amended scheme for a conjoint examination between the two Colleges, because of the opinion expressed by the College of Surgeons that the Apothecaries' Company should take part in the proposed examination.

The College of Physicians, we understand, arrived at this decision notwithstanding the utmost efforts of the Reverend Dr. Haughton to bring the Fellows to agree to the proposal, and we quite expected that they would do so.

It is necessary here for us to enlighten our readers

respecting misrepresentations which were made at the recent meeting of the Irish College of Surgeons respecting the views of those who have opposed this scheme.

The Irish conjoint examination project was got up avowedly for the purpose of defeating the Medical Reform Bill by effecting voluntarily, in a slipshod way, and to a limited extent, that which the Bill proposes to effect compulsorily, completely, and universally. This conjoint examination scheme contained two propositions—*First*: That the Colleges should combine to hold an all-round qualifying examination for Ireland at a fee of £31 10s., instead of £42, the aggregate of the present diploma fees. *Second*: That, therefore, each College should cease to grant its licence separately or to any claimant who had not passed the other College or some body approved by the other College. It has been publicly stated that we opposed conjoint examination for Ireland, and we take this opportunity to say that such an assertion is totally false. On the contrary—as the authors of this statement well know—we approved of the conjoint examination in the interest of the Irish student, and would have supported it in these columns if it had been put forward uncomplicated by the second of the two propositions. But we condemned and will continue to oppose the suggestion that the Colleges—especially the College of Surgeons—should be precluded from granting their licences, in future, to such students as prefer to take them separately or in conjunction with the licence of some body other than the College of Physicians. We believe that the Colleges have no legal power to divest themselves of their separate licence-granting functions, that if they had such power the Act would be suicidal, and that no reason whatever has been shown why Ireland should not do as Scotland has done—i.e., hold a conjoint examination without forcing any student into it, and without abandoning the right to licence separately those who desire to qualify themselves in this way.

We advise those who try to make capital out of a printer's error in our columns to apply to themselves their oburgation against "inaccuracy" of statement, and to abstain from making assertions as to our policy which anyone who chooses to refer back to our pages will find to be untrue.

Appropriately to the discussion of the Irish conjoint examination we may point out the utter inconsistency of those who are trying to run this conjoint examination against the Medical Reform Bill. They denounce the latter measure because it deprives the Colleges of their separate licensing powers, while, at the same moment, they advocate a scheme which produces the same result without securing thereby the benefits derivable from the Medical Bill. They try to get up a howl as to the financial loss which the Colleges would sustain from compulsory and universal conjoint examination, while they urge the Fellows of the College of Surgeons to regard with serenity the minimum loss of £1,100 a year, which, it has been proved, will result to the College from their own voluntary combination scheme. Was ever a policy so contradictory and ridiculous?

But, in truth, we do not believe that these considerations have much weight with those who use them so freely

to influence others. They resist medical reform because they like the *status quo*, and mean to keep it alive as long as they can, and whether it is kept alive with loss to the Colleges of privileges or of money does not make much difference: if the public suffer, so much the worse for the public.

Notes on Current Topics.

Quis Custodiet Custodes Ipsos.

MR. CLEMENT LUCAS has afforded an instructive illustration of the snares which candidates for surgical diplomas are sometimes called upon to avoid, and from the toils of which it is not easy to understand how escape is to be arranged. Mr. Lucas had been describing a case of Charcot's joint disease; and in commenting on the peculiarities of the affection, he referred to the fact that examples of it had been submitted to candidates at a certain examination in surgery conducted under the auspices of a well-known corporation, and that the examiners had chosen the patients for testing the knowledge of candidates in respect to *chronic rheumatic arthritis*. We are not informed whether this incident is of recent date, and the imagination is left to perform the not difficult task of supplying the name of the corporation in question; but the inference which Mr. Lucas and Dr. Buzzard—who, also, mentioned the fact—would draw from it is sufficiently obvious. It is quite possible that a candidate who recognised the real nature of the disease, and whose diagnosis must, therefore, be essentially unlike that arrived at by his examiner, would on this account suffer rejection as a consequence of his better knowledge, and though it is very unlikely either that many examiners could be guilty of so extreme an error of judgment, or that the occurrence could be frequently repeated, still the question irresistibly suggests itself whether the interests of surgery and of candidates for surgical qualifications do not demand a more generous use of skilled supervision in relation to the details of examinations than is always the case at present.

Grog.

SOME very shocking details of the way in which publicans treat their customers were recently brought to light at an inquest held on the body of an unfortunate woman whose death was attributed to over-indulgence in a villainous compound known as "grog." This horrible concoction was stated by a witness, to whom, also, its qualities as a beverage had commended it, to consist of an admixture of drippings and overflow from all the taps in a public-house bar. These, it appears, are all gathered together in one vessel, and then sold at sixpence a quart to whoever is weak enough—or mad enough—to ask for it. It is terrible to conceive the effects such a mixture must produce on those who habitually drink it; and how seriously it can undermine the health is proved by the statement of the coroner who conducted the inquiry already referred to, and who declared that this was the fourth victim of "grog" in connection with whose decease he had, within a short period, been called on to hold an investigation. The existence of an adulteration Act probably influences the

ale of this mixture thus charged with so heavy a bill of death in no prohibitive manner; but it is quite clear from the nature of the evidence that means ought to be taken to prevent the indiscriminate purchase of so hurtful a compound by the habitual inebriates who seem to be its chief patrons. It will probably be news to many that such stuff is a regular article of sale in public-houses, but there will arise no possible doubt of the necessity for interfering with the practice if it can be done. Brandy, whisky, beer, and gin, in varying proportions, and in association, are wholly unsuited to become an article of general consumption, however moderate may be the price at which the mixture is retailed.

M. de Lesseps' Fracture.

THE *Times*, in a recent issue, contained an account of the habits and character of the eminent creator of the Suez Canal; and among other personal anecdotes the article narrates that M. de Lesseps insisted on adopting his own form of treatment when he was so unlucky as to sustain a fracture of the arm. Instead of submitting to have the limb dressed in the ordinary way, and supported in a splint, he elected to do entirely without such assistance, and the only apparatus employed by him consisted of a handkerchief for a couple of days, after which time the hand was kept supported in the waistcoat until union and recovery were complete. This mode of procedure, though probably M. de Lesseps was unconscious of the coincidence, is exactly that which not a few authorities in surgery regard as the most scientific way of treating fractures. In a recent clinical lecture, Mr. Hutchinson, for instance, strongly advocated treatment of broken bones without submitting the injured limbs to the pressure and fixation incident to use of splints and strapping. In a majority of cases, moreover, such a course is not only possible, but probably, also, preferable. The ends of the bones, when once placed in apposition, have a tendency to preserve this position, and only in exceptional instances is there any danger of secondary displacement; such cases, of course, being of a kind to demand artificial support and fixture. M. de Lesseps thus, and in all likelihood unconsciously, pursued the course which improved surgery would have followed in treating his fractured arm. His indomitable strength of will and power of endurance, by the exercise of which alone, the writer in the *Times* seems to think, could he so treat himself, were useful and important assistants towards his early and easy recovery from the results of his accident.

Dr. Beaney.

THIS very well-known Melbourne practitioner has, we understand, succeeded in forcing himself into the Irish Academy of Medicine. Having been some years ago elected a member of the Dublin Pathological Society, he was entitled thereby to be a member of the Academy without ballot on the absorption of the Society into that organisation and on payment of the subscription. The subscription was paid, not by Dr. Beaney, but for him, and no direct application for co-option to the Academy was made by him, and the General Council, therefore, declined to receive his money or recognise his status as a member until they were advised by counsel that they

could not avoid doing so. They, therefore, took legal advice as to (1) whether the circumstances made him a member without ballot; (2) whether, being a member, they could expel him for some act done before the constitution of the Academy; and we hear that they have been informed that in law Dr. Beaney is a member, and that he cannot be got rid of unless he does something more to justify his expulsion.

No doubt the Reverend Dr. Haughton, who, notwithstanding a warning to be cautious how he identified the University with this gentleman, acted as Dr. Beaney's sponsor in Dublin, and thus, indirectly, made him a member of the Pathological Society and of the Academy, will be proud of the distinction thus achieved by his *protégé*. Considering that neither the General Council nor the Fellows of the Academy are consenting parties to the grant of the Fellowship to Dr. Beaney, we hope that no Fellow will think himself called upon to dissociate himself with the Academy because that gentleman has thus forced himself into it.

The Notification of Infectious Diseases.

WE understand that Mr. Hastings, M.P., will not this year introduce the Bill for compulsory notification by the medical attendant, which heretofore he has taken charge of for the Social Science Association, nor will Government touch the question. Mr. Meldou's Bill for Ireland, for notification primarily by the householder and secondarily and voluntarily by the physician, will be introduced if the progress of the session gives any promise of its passing; but the "Vigilance Committee," who are anti-vaccination, anti-vivisection, and anti-everything, and who are represented in the House by Mr. Hopwood, Mr. Burt, and one or two other Radical members, will block and oppose any such Bill.

Meanwhile the Brighton Town Council is trying to force the compulsory notification system on the physicians of that town, who are fighting for their freedom. If the Town Council should succeed, no doubt their Bill will be sent to the same committee which last year refused to hear any evidence on behalf of the medical profession, in which case, no doubt, the obnoxious system will be extended to Brighton.

Housing the Poor.

THE long debated question of housing the poor of large towns is now to become a question for consideration by a Royal Commission specially appointed for the purpose, and on which His Royal Highness the Prince of Wales will have a place. The direct interest taken by the Prince in this matter was very practically demonstrated last week, when he paid a personal visit of inspection with Lord Carington and Dr. Buchanan to some of the poorest and worst courts about Holborn and St. Pancras. It is quite possible to hope that some tangible result will after all be obtained from the public agitation recently provoked over the dwellings of the poor; and if this should really be the case it will be easy enough to forget the vast amount of false sympathy that has been expressed, and the paltry sentimentalism exhausted on the subject. What is wanted is less talk and more action; and this at last we seem to be on the eve of having. The

work before the Commission is heavy, and in much of its details probably wearisome; but that it will be thoroughly and earnestly performed we cannot fail to be convinced. As Chairman of the Commission, Sir Charles Dilke, whom report speaks of in this connection, will be able to render invaluable service, and to assist the deliberations that will ensue by providing the members of the Commission with his accumulated experiences of the necessities that call for such action as will ensue. It would be impolitic to anticipate that the committee can report in time for any legislative interference during the current session of Parliament, even supposing such a step should be recommended; and it is likely that with abundant time for subsequent public discussion of what has been accomplished during the sittings of the Commissioners a better and more enduring set of benefits will be conferred upon the classes to be assisted.

The Liverpool Poisoning Case.

FROM a local paper we learn that a confession is alleged to have been made by one of the women now under sentence of death in her Majesty's prison, Kirkdale, to the effect that the poison employed was obtained by soaking arsenical fly papers, of which sixteen can be procured for a shilling, in water. The papers, it is said, were allowed to stand for a few hours, and were then taken out singly, each one being well squeezed, so as to extract all the moisture therefrom. The liquid remaining, which was almost colourless, but which probably contained from eight to twelve, or even sixteen, grains of arsenic, was poured into a bottle, and the mixture was then ready for its diabolical use.

It is now stated that the local police will for the future forbid the sale of these papers, except under the conditions imposed by the Sale of Poisons Act. The ease with which poisons can be procured in this country by all classes of persons, in spite of Acts of Parliament, is a constant ground of complaint. The authorities must have been aware long before the occurrence of this tragedy, or rather, series of tragedies, that many so-called fly papers contained arsenic, and arsenic is one of the poisons the sale of which is prohibited, except under restrictions, and yet no obstacles have been placed to the purchase by any child or adult ignoramus or criminal of these dangerous articles. Probably no restrictions would have been placed on their sale but for this rude awakening of the official mind from slumber. In Prussia, on the contrary, no such rude awakening has been necessary. Arsenical fly papers were placed last year, as noted in these columns, amongst the list of dangerous articles, and their sale was prohibited, except under the conditions applicable in the case of other well-known poisons. We venture to express the hope that what should have been done before will be done forthwith, not in one locality, but throughout the country, and that these papers, saturated with deadly poison, will not for the future be so easily procurable.

THE Princess Louise, Marchioness of Lorne, on Saturday afternoon visited the Westminster Hospital, and was conducted through the wards by Dr. Allchin. Her Royal Highness expressed much interest in her visit.

The Profession at the Levee.

ON Thursday last a Levée was held at St. James's Palace by His Royal Highness the Prince of Wales, on behalf of Her Majesty the Queen, the presentation to this court being, by Her Majesty's pleasure, equivalent to presentation to the Sovereign. The following members of the profession had the honour of presentation:—Sir William Bowman, M.D., F.R.S., by the First Lord of the Treasury, on being created a baronet. Sir Prescott Hewett, F.R.C.S., by the Earl of Kenmare, on being created a baronet. Deputy Inspector-General Belgrave Ninnis, M.D., on promotion, and Surgeon-Major T. H. Hendley, by the Secretary of State. Dr. George Fleming, President of the Royal College of Veterinary Surgeons, also had the honour of presentation by the Duke of Cambridge, on being appointed head of the Army Veterinary Department.

Pallida Mars.

WE have, we fear, added a new marvel to the wonderful celestial phenomena of this season, by introducing to our readers a Pallida Mars. We hasten to explain, however, that we have no reason to believe that the fiery planet has been "sicklied o'er" by volcanic dust, or that the War God has come amongst us, and like "an apothecary on a white horse" has ridden forth "on his vocation," calling to mind that ancient prototype "Death in the Revelation." The fact is, that, by the curious blunder of a printer, steeped perhaps like Keats to the very lips in Lemprière and Took's Pantheon, Pallida Mars has been substituted for Pallida Mora, just as "The Child of Harrow's Pilgrimage" was substituted for "Childe Harold's Pilgrimage," on the title page of the first edition of Byron's great poem. The error does not discompose us, for the capital R in regumque which should have begun a new line, will show the initiated that the quotation was not repeated parrot-wise, but came straight from the *Ars Poetica*.

Workhouse Surgeons as Coroners.

IN the House of Commons last week Mr. Sexton asked the Chief Secretary to the Lord Lieutenant of Ireland whether Dr. Parke, the coroner for the northern division of the County Down, is also medical officer of the Newtownards (County Down) Union Workhouse; whether on the 17th ult. an inquest was held on the body of an inmate of the Newtownards Workhouse, and it became necessary for two justices of the peace to hold the inquest, as Dr. Parke, in his capacity of workhouse medical officer, had to appear as a witness in the case; and whether Dr. Parke would continue to hold the offices of coroner and workhouse medical officer, with the result that he never can act as coroner whenever it may be needful to hold an inquest on the body of an inmate of the workhouse? Mr. Trevelyan said the facts were as stated in the question. The Local Government Board had under consideration the question whether Dr. Parke should continue to hold the office of medical officer to the workhouse if he retained the position of coroner to which he had been elected. Mr. Sexton gave notice of a further question on the subject next Thursday.

It is a question whether the rare necessity for holding

an inquest on a workhouse patient would be a legitimate reason why the Local Government Board should "deem" the medical officer of the Union Hospital "unfit" to continue in office. In our opinion it would be totally unjustifiable to remove a workhouse medical officer for such cause, and we are confident that if one were so deprived of office a court of law would reinstate him. However it may be contended that it is inconvenient for such officer to be a coroner, it could not be for a moment maintained that his duties in the workhouse are materially interfered with by his holding the second office, and, in any case, the Local Government Board could not reasonably "deem" him "unfit," or call on him to cease from being coroner until some occasion arose in which his medical duties were interfered with by his coronership. If anyone has a right to object to the plurality of offices it is those who pay the coroner, and it appears by their election of him that these are quite content with the arrangement. We need hardly observe that Mr. Sexton's question is not prompted by any consideration of this sort, but is simply politico-religious.

The German Congress for Medicine.

THE third Congress for Medicine will be held in Berlin from the 21st to the 24th of April. The President, as usual, will be Professor Frerichs. A large part of the programme has already been arranged. There will be, 1st day, a discussion on "Genuine Pneumonia," introduced by Herren Jürgensen of Tübingen, and Fräkel of Berlin; 2nd day, one on "Poliomyelitis and Neuritis," introduced by Herren Leyden of Berlin and Schultze of Heidelberg; 3rd day, one on "Nervous Dyspepsia," introduced by Herren Leube of Erlangen and Ewald of Berlin. A number of other papers are already announced, and amongst them one by Dr. Hermann Weber of London, on "School Hygiene in England, particularly in regard to Infectious Diseases."

Poor-law Superannuation.

WE are asked to announce that at a meeting of the Council of the Poor-law Medical Officers Association held at their rooms, 3 Bolt Court, on the 19th of February, it was resolved, "That a Memorial should be addressed to the President and Fellows of the Royal College of Physicians; the President and Council of the Royal College of Surgeons; the Master and Wardens of the Society of Apothecaries, praying that they will severally memorialise Her Majesty's Government in favour of an amendment of the Poor-law Medical Officers' Superannuation Act, whereby its present permissive clauses may be made compulsory."

Solidified Creosote for Toothache.

CREOSOTE is a popular remedy used for the pains caused by caries of the teeth. The *Revue de Thérapeutique* says that as its excessive fluidity frequently occasions bad accidents in the mouth of the persons that use it, it can be solidified by the addition of a certain quantity of collodion, 0 grams to 13 grams of creosote. This mixture is more manageable than the simple creosote, and forms a varnish which closes the orifice of the tooth and prevents the air from influencing the dental nerve.

Recent Analysis of Human Milk.

IN an article in the *Jahrbuch für Kinderheilkunde*, Bd. xx., Heft 4, Dr. Emil Pfeiffer, of Wiesbaden, records the results of his recent investigations into the composition of this, the most important article of diet for children. The analyses performed were very numerous (109), and were made to include the most varied kinds of milk, from an early to a late period of lactation, milk from primiparæ and from multiparæ, and lastly, milk from women in the various grades of society. After showing that analysts, with the exception of Vernois and Becquerel, have relied on too small a number of samples, and that the methods of analysis made use of by these are unreliable, and that they have been improved upon, he proceeds to give his own results.

He first shows the ever varying proportion of colostrum in milk, that on the first day after delivery it is 8.6 per cent.; from the third to seventh, 3.4 per cent.; in the second week, 2.28 per cent.; in the second month 1.84 per cent.; in the seventh month, 1.52 per cent.; that thus, in the early period of lactation the proportion of albumen is high, and that the sinking is very gradual. The proportion of fat is a varying one, but it usually increases in the later periods. The quantity of sugar is at first very small, it then increases very rapidly, and later on more slowly. The specific gravity and the quantity of solids vary with the varying proportion of fat.

According to our author, the characteristic of a young milk is that it contains a greater proportion of albumen and salts; and of an old, that it contains a lesser proportion of albumen and salts, and a higher of sugar.

By carefully measuring the daily quantity of milk given in a large number of cases and for long periods, he has arrived at the conclusion that the quantity constantly increases up to the 28th week of lactation, and then diminishes. Reckoned according to the weight of the child, the infant takes in an increasing quantity, especially from the fifth to the tenth week, and after this period the increase is smaller. The increase in weight of the infant is also greatest in the period of corresponding greatest increase in the quantity of milk. The milk of older nurses contains less fat and more albumen, sugar, and salts than that of younger women. Abundant and wholesome food improves both the quantity and the quality of the milk; food rich in albumen increases the proportions of albumen and fat, and diminishes those of sugar and salts, whilst a vegetable diet poor in albumen has the contrary effect.

The influence of menstruation varies with the period of lactation in which the menses appear. When they first return towards the end of the period of lactation, the quantity of milk supplied diminishes considerably, and undergoes no increase later on, and with the exception of lessened increase in weight of the infant no disturbances are noted. In those cases in which the menses return early there is also a diminution in the quantity of milk, but the diminution in this case is only transitory, after the period is over the supply again increases. Many children show no disturbance whatever at these times, but the majority become restless, and cry a good deal, the motions become frequent and liquid, green and

lumpy. In one case examined Dr. Pfeiffer noted an increase in the quantity of milk, and of contained sugar, with diminution of albumen, in other cases increase of the salts, and diminution of albumen and sugar. The changes, however, are not constant nor uniform, and this explains why some children do not suffer at the menstrual periods of their nurses whilst others do.

In agreement with many other observers he found that the milk first drawn from the breast is blue, watery, and poor in fats; whilst that which appears later is yellower, thicker, and more creamy. In testing the milk of a wet nurse, therefore, it should be borne in mind that that which is first drawn is not a fair sample, and probably the condition of the woman's own child will give better evidence of her fitness for fulfilling the duties of a wet nurse than any examination of the milk by an expert.

The German Congress for Surgery.

THIS Congress will be held in Berlin from the 16th to the 19th of April. The scientific general meetings will take place in the Aula of the Royal University in the afternoon of each day, and the mornings will be devoted to demonstrations of cases and preparations in the University clinics and in the Royal Charité. Intending visitors are requested to address themselves up to the 15th of March to the President, B. von Langenbeck, Wiesbaden, and after that date to the same gentleman, Berlin W., Hôtel du Nord.

Jamaica Dogwood.

DR. H. K. WELLS, Erie, Illinois, reports most favourably upon the use of the fluid extract of "pescidia erythrina" in $\frac{1}{2}$ j. doses in syrup, at bed time, in the treatment of a case of hysterical mania, where all other treatment had failed. The dose was ordered to be repeated every four hours until quietude or sleep ensued. The treatment was commenced on the 2nd of October (*The Therapeutic Gazette*), two doses being given that night. On the 5th of October a vast improvement in the patient's condition was noticed, and by the 7th Dr. Wells' services were dispensed with.

Dr. Elmore Palmer, of Boulder, Colorado, in the same Journal notes the results obtained in the case of his own wife, who suffered from most obstinate attacks of nervous headache, a legacy inherited from her father. Treatment of every description had failed to give relief. The effect of the fluid extract of Jamaica dogwood was immediate, given in a tea-spoonful dose. Whenever she is now troubled with a tendency to the recurrence of one of these attacks, a dose of the extract at once disposes of it, and peace and happiness reigns in the Doctor's household.

With regard to the introduction of "new remedies," disappointment is too frequently experienced, when these, which are highly vaunted by others, are put to the test of clinical experience in one's own practice. Yielding to this sense of disappointment, we are always liable to look with incredulous eyes upon the claims of new drugs, and consequently, deprive ourselves of many a useful addition to our therapeutical resources. This is a danger to be guarded against. Failure may possibly

be due to a faulty selection of suitable cases on our own part, to idiosyncrasy on the part of the patient, or to some error in the proper method of administration, or in the proper dosage. We ought, therefore, to give the drug a fair and impartial trial, and to judge of the results with unbiassed minds. We certainly have not, as yet, exhausted the secrets of nature, and, as of late years many new and most useful drugs have been brought into use for the benefit of suffering humanity, so we know not what great and important discoveries may be made in the future. We may often be deceived, but not always; and one good remedy may readily stand sponsor for the time we have given to demonstrating the shortcomings of many useless ones. Even one useful addition to our armamentarium out of a hundred useless ones may be reckoned as good work done for the cause of medicine. What might, as far as previous knowledge and means of treatment are concerned, have proved an intractable or even hopeless case, may, by the good effects of the new and useful remedy, be brought to a favourable issue.

The Third International Otological Congress

THIS Congress is announced to be held in Basle from the 1st to the 4th of September of the present year. It is requested that gentlemen intending to read papers, &c., and those even who simply intend to be present, will signify their intention not later than May 15th to some member of the committee or to the President, Professor Burckhardt-Merian, Basle.

Iodoform Plaster.

DR. POPE recommends the use of this plaster in cases of glandular enlargement, bursitis prepatellaris, pleuritic effusion, and chronic epididymitis. In the cases in which he has tried it (*Wiener Med. Blätter*) there was a marked diminution in the size of the tumour, or the amount of effused fluid, in what may be considered a short time, i.e., ten days.

The formulas he uses are 1st. R Emplastrum iodoformi fortius, one part iodoform to two parts emplastrum adhesive and emplastrum plumb.

2nd. R Emplast. iodoformi to six parts of the plasters named. The plaster is spread on leather, and is left to remain *in situ* for six days. The strong preparation is recommended in glandular enlargements, &c. The weaker proves useful in the case of boils, minor injuries, &c. The great drawback to the use of iodoform is its inconceivable odour. One must feel thoroughly assured of the benefits to be derived from its use to put up with it.

THE creation of Surgeon-General William Guyer Hunter, M.D., to Knighthood of the Order of Saint Michael and Saint George, "in recognition of services rendered during the recent outbreak of cholera in Egypt," was officially gazetted on Friday last.

A LITTLE boy, *set.* 11, died at Tottenham last week from hydrophobia occasioned by the bite of a dog in October last. The wound, which was in the thumb, healed quickly after it had been poulticed, and no untoward sym-

ptoms manifested themselves until a day or two before the boy's death, nearly five months after the occurrence.

A SHOCKING tragedy was perpetrated at the West Derby Union Hospital on Sunday, when a patient, who had been recently discharged from the hospital cured, made his way into the nurses' room, and almost severed the head from the body of a nurse named Groves, 50 years of age, and then cut his own throat. No motive can be assigned for the crime.

TO-MORROW (Thursday), at 8 p.m., Dr. Neale, editor of the *Medical Digest*, is announced to deliver a lecture at Dr. Parke's Museum of Hygiene, explaining the action of the "Chemical Lung" in supplying fresh, pure air, independent of ventilation, as adapted to sick rooms, hospital wards, and theatres, or other public buildings. Dr. B. W. Richardson, F.R.S., has promised to preside.

TOOTHACHE is treated by Dr. Kirchbauer by the internal administration hourly until relief commences to be effected of tablespoonful doses of a mixture consisting of—chloral, butyl, 5·0; glycerin, 30·0; aq. dest., 100·0; syr. cort. aur., 20·0; ol. foniculi, gtt. 5 (*Pharm. Post.*, xvi., 537). He also uses what he calls "chloral-carbol wadding." A small plug of the medicated wadding is placed in the aching tooth.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 29, Madras 65, Paris 24, Geneva 29, Brussels 22, Amsterdam 28, Rotterdam 25, The Hague 24, Copenhagen 22, Stockholm 22, Christiania 23, St. Petersburg 38, Berlin 22, Hamburg 24, Dresden 30, Breslau 27, Munich 28, Vienna 28, Prague 38, Buda-Pesth 27, Rome 35, Turin 32, Venice 33, Lisbon 41, Philadelphia 25, and Baltimore 22.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 20·1 per 1,000 of their aggregate population. The death-rates in the several towns were:—Portsmouth 11; Wolverhampton 14; Cardiff 15; Halifax, Leicester 16; Oldham, Leeds, Birmingham, Blackburn, Norwich 17; Edinburgh, Brighton 18; Bristol, Derby, Bradford, Nottingham, London; Plymouth, Hull 20; Birkenhead, Salford, Sheffield, Huddersfield 21; Bolton, Manchester 22; Newcastle-on-Tyne 23; Preston, Liverpool 24; Sunderland, Glasgow 25; Dublin 31.

THE highest annual death-rates in the large towns last week from diseases of the zymotic class were—From whooping-cough, 2·4 in Bolton, and 1·2 in Huddersfield; from scarlet fever, 2·9 in Leeds, and 1·7 both in Sheffield and Newcastle-upon-Tyne; and from measles, 2·4 in Derby, 1·9 in Salford, and 1·3 in Oldham. The 48 deaths from diphtheria included 26 in London, 8 in Glasgow, 5 in Hull, 2 in Liverpool, and 2 in Leeds. Small-pox caused 10 deaths in Sunderland, 3 in Birmingham, 2 in London, and 1 in Liverpool.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

ARBROATH.—INFIRMARY APPOINTMENT.—A meeting of the Directors of the Arbroath Infirmary was held on the 20th inst., the President, Mr. Muir, of Abbey Bank, presiding, to appoint a lady superintendent of the infirmary in room of Miss Liberty, who has resigned. The Committee submitted the names of three ladies, all of whom they reported were well qualified for the appointment. Miss Francis E. Kay, of the Western Infirmary, Glasgow, was unanimously appointed on the recommendation of the Committee.

THE INTERNATIONAL HEALTH EXHIBITION.—The Lord Provost of Glasgow has issued a circular drawing attention to the International Health Exhibition to be held in London during the ensuing summer, under the patronage of the Queen and the presidency of the Prince of Wales, and inviting the attendance of those in Glasgow able and willing to take part in the exhibition at a conference to be held within the council chambers shortly. By this exhibition it is proposed to illustrate chiefly food, dress, the dwelling, the school, and the workshop, as affecting the conditions of healthful life, and the most recent appliances for elementary school teaching and instructions in applied science, art, and handicrafts.

KIRKWALL.—DEATH OF DR. McROBERT, WESTRAY.—This gentleman died suddenly in that island on the 21st inst. Dr. McRobert was a native of Aberdeenshire, and practised in Ross before receiving his appointment in Westray. He was in the prime of life.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 16th inst., the mortality in Edinburgh was 79, and the death-rate 17 per 1,000. There were 13 deaths under 1 year, and 17 above 60, of which 2 were above 80 and 1 above 90 years. Diseases of the chest accounted for 40 deaths and zymotic causes for 11, of which 1 was due to diphtheria, 3 to scarlatina, and 3 to measles, the intimations of these diseases for the week being 0, 42, and 157.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 16th inst., were at the rate of 25 per 1,000 per annum of the population, as compared with 27 in the previous week, and 29, 28, and 29 in the corresponding weeks of 1883, 1882, and 1881 respectively.

AN ADULTERATION CASE AT GLASGOW.—Before Sheriff Balfour, Glasgow, last Thursday, Duncan Brown, grocer, was charged with having sold $\frac{1}{2}$ lb. of black pepper which contained about 20 per cent. of added starch. The Sheriff, after Dr. Tatlock and Professor Dittmar, analysts, had been examined, said the prosecution was the first of the kind he had heard of in Glasgow. The evidence of the analysts was that the effect of the added starch was not injurious to the pepper in any way, but only reduced its strength. It might be said for the respondent that he bought the pepper in the ordinary way from a wholesale merchant, and he was not aware of the inferiority of it. At the same time, under the Act he was liable for the sale. The evidence of the chemists practically was the same, and established the addition of the 20 per cent. of foreign starch. In the whole circumstances, seeing that it was the first prosecution of the kind, he inflicted the mitigated penalty of 10s.

SCOTCH VITAL STATISTICS.—From the official returns of the Registrar-General for the week ending the 16th inst. we learn that the death-rate in the eight principal towns of Scotland was 20·9 per 1,000 of estimated population. This rate is

4.9 below that for the corresponding week of last year, and 3.8 below that for the previous week of the present year. The lowest mortality was recorded in Leith, viz., 14.1 per 1,000; and the highest in Glasgow, viz., 25.3 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3.0 per 1,000, being 1.0 below the rate for last week. Acute diseases of the chest caused 113 deaths, or 4 more than the number recorded during the previous week.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—The important debate on "Albuminuria," which was referred to in our last, was resumed on Tuesday, under the presidency of Professor McCall Anderson. Professor Gairdner opened the proceedings with a well-considered address, and was followed by Dr. Mortimer Granville, of London, in a highly-coloured and one-sided argument, which, if followed out to its logical conclusion, would be fraught with considerable danger, and would meet with strong opposition from Sir James Paget, Dr. Dickinson, and other thoughtful men on the same side. Dr. Granville was followed by Dr. Mahomed, of Guy's Hospital, with a paper on the subject, after which the debate was again adjourned. A *résumé* of this debate will be found in another column, but we purpose reverting to the whole debate in detail at its conclusion.

DONATIONS TO EDINBURGH CHARITIES.—We understand that Mr. William Renton Clapperton, Edinburgh, as executor for a gentleman deceased, has, from the funds placed at his disposal by will, made payment of the following donations free of Government duty:—To the Edinburgh Royal Infirmary, £500; Convalescent House, £100; Royal Edinburgh Hospital for Sick Children, £50; Institution for Relief of Incurables, £25.

Correspondence.

THE FELLOWSHIP OF THE LONDON COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—"M.D." has done good service in calling the attention of the profession to the gross wrong done to many who have reason to complain of their being so continuously passed over by the powers that be in the College in their yearly selection of Fellows. The College has become a "cliquey" body where the staff, of some hospital, have their own way, and where personal feeling is allowed to have full swing. In the "good old times," an Oxford or Cambridge graduate was sure of his Fellowship sooner or later. I know of one man, one of your list of 25, who felt himself much and rightly aggrieved when a man, many years his junior, a specialist in the same line, and that speciality one not in favour at the College, was made a Fellow over the heads of many of his seniors because he was put forward by the clique party of his own hospital, on whose staff he held a recent appointment. The College is losing its prestige and its Fellowships, therefore, their value.

I am, &c.,

ONE OF THE TWENTY-FIVE.

Feb. 21, 1884.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have noticed a letter in your issue of the 20th inst. headed "The Fellowship of the London College of Physicians," in which M.D. has done me the compliment of placing my name amongst those of the Members whom he deems worthy of election to the Fellowship. In his effort "to remove the mystery as to the line of action of the College in the selection of its Fellows," which, as I think, requires no further elucidation than that it acts on the principle actuating very generally the privileged bodies of London, M.D. does not suggest any positive reason, and none of those are satisfactory of the series he proposes in an ironically inquiring style, as if he considers them outside

the bounds of possibility. Perhaps it may not have occurred to him that, of the Members whose names he has flatteringly recorded, there may be several who have not accepted the College invitation.

For myself, I have felt it to be a favour twice conferred on me within the last twelve years, in official proposals of nomination for election, which offers I have considered to be equal to an election on two occasions, from which I have recoiled, and therefore it becomes my duty to remove imputations from the College so far as concerns my own case. It may occur to inquirers that there must have been special reasons for this abnegation of professional position, so justly coveted by many of its members. Such reasons do exist, which I have assigned, to the effect that, in my opinion, M.D.'s in the public services who receive decorations from the State for professional services rendered bring honour to our profession, and more particularly to the Colleges of which they are members, and that those bodies act creditably to themselves which recognise the honours won by their own members.

I believe there were such instances by our College in the last century, but I am not aware of any in my own time, when other medical corporations of both Scotland and Ireland have afforded them with prompt enthusiasm. My hope is that, in the near future, the Royal College of Physicians of London may become alive to its reputation for professional *esprit de corps*, and may, likewise, show promptitude in backing up any recognition of meritorious services made by the Government, and that those coming after me, being in my circumstances, may find their names published in a list of Honorary Fellows.

I am, Sir, yours, &c.,

WILLIAM R. E. SMART, M.D., R.N., K.C.B., K.L.H.,
Honorary Physician to the Queen; ex-President of the
Epidemiological Society.

February 23rd.

BICHLORIDE OF MERCURY INJECTIONS IN GLEET.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to point out with reference to your article on this subject in your last impression, that my original paper, in which this treatment was recommended was published in the *British Medical Journal*, of 23rd April, 1870, thus many years before the recent recommendations on the continent and America. Of course, I exclude from this treatment cases of gleet due to stricture. The strength of the solution which I found to be most beneficial was from gr. j. to gr. ij., to ʒviij. of water. I quote the following from the paper in question:—"I need not say that this is an agent that ought not to be tampered with, nor indiscriminately employed. . . . The pain occasioned by the application of the bichloride is at first somewhat more severe than that produced by the nitrate of silver, but not nearly so permanent. Frequently one injection is found to arrest the discharge. Should one application not suffice to arrest the discharge it must be repeated, not, however, within a week or ten days."

I am, &c.,

D. CAMPBELL BLACK.

Glasgow, Feb. 22nd.

THE MEDICAL ACTS AMENDMENT BILL

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the leading article of your last issue you take exception to a term employed by me during the recent debate at the Royal College of Surgeons on the Medical Acts Amendment Bill in reference to certain statements that have been repeatedly made by promoters of the Bill, namely, that many of them (the statements) are "scarcely honest." Be assured I am very sensible of your kindness in being magnanimously disposed to excuse my having used the term as being a probable result of my "effervescence of rhetoric" and "agonies of oratorical parturition." You suggest, however, that as the expression may have been the result of a "slip" that prompt *amende* should be made. I may state that nothing could be further from my intention at any time than to say anything personally offensive to you, nor on the occasion above referred to were any observations of mine directed to you individually. I regret, however, that I find myself unable to withdraw the expression complained of, and I

venture to repeat again that many of the statements that have on various occasions been made in reference to the reasons for passing the Bill and its probable results when passed, deserve to be stigmatised as "scarcely honest." These may be briefly summarised:—

1. That there exists an ignoble traffic in the sale of diplomas, notably in the Scottish Corporations.

2. That examinational defects formerly observed in these and other licensing bodies are still to be found.

3. That the Bill is the result of a demand made by the "voice of the profession."

4. That after the Bill is passed the existing medical and surgical corporations will not be losers either as regards finance or prestige.

5. That those who are not favourable to the Bill in its present form are *ipso facto* "enemies of reform."

The expression I made use of—deliberately, I may add, and not in any haphazard way—may not have been, as you say, "worth notice" on your part. However that may be, I feel confident that anyone possessing a knowledge of the character of the examinations in the various medical and surgical licensing bodies of the United Kingdom, and who regards the subject calmly, dispassionately, and free from bias, will admit that the term "scarcely honest" is not too strong a one to apply to the above five statements, which have been so persistently, pertinaciously, and obstinately thrust upon a bewildered, befooled, and ignorant public.

Yours, &c.,

5 Merrion Square, Dublin.

WILLIAM STOKES.

Feb. 23, 1884.

[If all the statements referred to by Mr. Stokes were incorrect that fact would not justify an imputation on the "honesty" of motive of those who put them forward. It would be quite possible to believe that they were the result of erroneous information or of misconception, not of dishonesty; the language used by him is, therefore, quite unjustifiable. But, as a fact (notwithstanding what Mr. Stokes says), the statements to which he refers are true, and proved to be so. The evidence as to the Scotch emigration and the causes of it supplied by a correspondent to our pages last week did not, as Mr. Stokes would lead us to believe, refer to bygone times. It was given two years and a-half ago by men most of whom were then, and are now, in daily observation of the Scotch traffic. That that traffic has not now ceased is proved by the pass-list published in our issue of only two weeks ago (Feb. 13, page 151), from which it will be seen that of 74 examinations passed for the Edinburgh double diploma 24 were by Englishmen, 26 by Irish, 15 by foreigners, and only 9 by Scotchmen.]

With evidence such as this before us we are in a position to assess the value of Mr. Stokes's five pronouncements. The only proof which he attempts to put against the facts, figures, and testimony quoted in our columns is the observation by himself and two other visitors of one single examination for the double diploma; and knowing what we do of the value of such isolated means of observation and of the verdict given by gentlemen who accorded high praise to examinations which are notoriously contemptible, we certainly prefer to depend on the evidence of facts and figures which Mr. Stokes well knows that he cannot question. We shall be in a better position to judge how far that gentleman is an "enemy to reform" when he refers us to the speeches made, letters written, and suggestions offered (if any) in advancing of reform, or we should rather say, not in hostility to it. We have never heard of him distinguishing himself in this way.—ED.]

A PRIZE, or prizes, is to be offered for a cheap and palatable non-intoxicating beverage. It is hoped that funds will be provided sufficient to offer two handsome prizes of £700 and £300 respectively. A well-known analyst has been consulted, and has reported favourably on the conditions to be fulfilled by each competing beverage.

Literary Notes and Gossip.

THE decision of the judges respecting the essays for the Warren Prize on the subject of Cancer has been announced. Six essays were presented, but none were deemed worthy of the prize.

AMONGST journalistic changes we may mention that the sub-editor of the defunct *Medical Examiner* succeeds Dr. Cholmeley as Editor of the *Medical Times*; and that Mr. Kenneth Millican has resigned the Editorship of the *Midland Medical Miscellany*.

A ROYAL Commission is to report on the whole question of the dwellings of the poor, and the composition of the commission will include among others His Royal Highness the Prince of Wales. Sir Charles Dilke will act as chairman, and an exhaustive inquiry is to be instituted.

DR. WICKHAM LEGGE's Bradshawe Lecture on Cardiac Aneurysms has at length assumed a printed form, having just been issued as a pamphlet by Messrs. Churchill. Unlike the other lectures delivered under the same auspices this had not hitherto been made accessible by publication in the medical journals. A copious bibliography is appended to the work, which has made of it a very useful contribution to medical literature.

"A WAREHOUSE wanted for the library of a medical man," will be a common heading for advertisements in the future, if an American contemporary's prediction is verified. Commenting upon a recently issued English work of large dimensions, the writer says: "The result of the combined efforts of writer and publisher of this literary balloon, is a volume which, if it should be the beginning of a fashion, would soon make it necessary for every doctor to rent a warehouse for the accommodation of his library."

IT is worthy of record, as a sign of the spirit animating modern conceptions of scientific merit, how the name of Darwin has been honoured in Paris in a way that our French neighbours may be deservedly complimented on. A proposal having been made to name a principal street in the French capital after the immortal evolutionist, it was met with immediate approval by the authorities, and henceforth the Rue de Darwin will testify to foreigners that appreciation of merit can be extended in France even to those who are not claimed as sons of the soil on which the memorials to them have been raised.

THE author of the Fothergillian Prize Essay for 1883, Mr. Norman Porritt, L.R.C.P. Lond., &c., has recently issued the work, for which the gold medal was awarded to him, in the shape of a handy and tastefully got up volume. Special value attaches to it on account of the large number of cases included in it, and illustrations of the efficacy of operative interference in treatment of diseases of the chest with effusion, the full title of the work being "The Operative Treatment of Intra-Thoracic Effusion." Messrs. Churchill are the publishers.

BEASLEY'S "Book of Prescriptions" has recently made its appearance for the sixth time as a new edition, and has undergone very careful revision with the effect of preserving the usefulness it possesses for the practitioner and student. A good many of the prescriptions which seemed out of place in a modern work of the kind, and were retained in the fifth issue of the work, have now been discarded, while all necessary additions have been introduced as required. The volume deserves all the success it has achieved in the past, and in a great number of instances it will prove a valuable assistant to the busy practitioner.

AMONG the more important new works issued during the present month, may be mentioned Dr. Thudichum's "Treatise on the Chemical Composition of the Brain," a work that is destined to take an important part in future medico-legal trials, Daniell's "Text-book of the Principles of Physics," and Heitzmann's "Microscopical Morphology of the Animal Body." Of new editions of established

works, the following are before us: Whittle's "Manual of Practical Materia Medica," Parrish's "Treatise on Practical Pharmacy," (5th), Fothergill's "Physiological Factor in Diagnosis," (2nd), and Warren's "Treatise on Hernia," (2nd).

A NEW monthly periodical with the title of *Flame*, has been started in Berlin, the object of which is to further the cause of Cremation. *Flame* edited by Julius Stein, Second President of the Berlin Cremation Society, will give information concerning the history, objects, and usefulness of the movement, and will publish communications from the various societies formed to promote it. It will also contain papers on kindred subjects, cemetery affairs, inspection of bodies, prevention of the dangers of apparent death, prolongation of the period allowed for disposal of the dead, erection of mortuaries, &c. The movement will not be permitted to die out, and it has already found supporters, especially among the physicians. The price will be four marks yearly.

LITERARY necessities are to be freely provided for in connection with the forthcoming Health Exhibition at South Kensington, and we learn that an exhaustive series of explanatory and scientific manuals will be issued in the shape of guides to the various sections of the exhibition. Pictorial illustrations, too, will be freely introduced, and the authors entrusted with the production of the handbooks are all gentlemen specially fitted by their researches and inquiries to achieve the labour confided to them. In the Dress section an especially elaborate guide is to be forthcoming, in which the history of clothing from the earliest times down to the present will be described, and pictures will be presented to illustrate the gradual growth of civilised excesses in the form of necessary decoration. Other subjects also will be similarly exhaustively dealt with, and a really valuable library of reference books is likely to be the result.

A DICTIONARY of Surgery written in accordance with modern views and discoveries has long been felt by surgeons to be a want of the time, and it is satisfactory, therefore, to learn that such a work has at length been projected by Messrs. Smith, Elder and Co. The editorial duties in connection with it have been undertaken by Mr. Christopher Heath, than whom no one more thoroughly well qualified to fill this difficult post could have been selected. It is confidently assumed that two years will see the completion of the book; which is to be cast on lines somewhat similar to those pursued in the construction of Quain's "Dictionary of Medicine." The surgery, however, will probably be somewhat less bulky in form, all the articles will be signed, and several of the best known and most eminent authorities on special subjects have already promised to contribute articles.

Two Medical Directories have been issued during the past few days, "The Irish Medical Directory," edited by Dr. Jacob, of Dublin, and the "Australian Medical Directory," edited by Mr. Ludwig Bruck. The former has done good service to the profession for many years past, and is too well known to need more than a passing reference. The Australian on the other hand is a new venture, and betokens the rapidly increasing importance of our Australian, New Zealand, and Tasmanian Colonies, and the prominent position the medical profession must necessarily occupy wherever British enterprise opens up ground for our overgrown population. Beside the Directory proper, there is a *résumé* of all the laws relating to the Colonies; the prospectuses of the Colonial Universities, and a "Short History of 130 Universities and Medical Colleges in all parts of the World." Considering the difficulties which such a first undertaking involves the editor must be congratulated on his work. The price, however, fifteen shillings, is absurdly high, and almost prohibitive for a work of 200 pages.

DR. OLIVER, of Harrogate, has brought out a useful little book on "Bedside Urine Testing." The object of the work is to introduce the testing of urine by test papers instead of by the usual chemicals and re-agents hitherto employed. There can be little doubt that physicians will be glad to exchange caustic and corrosive solutions which

they are now obliged to carry about with them for the simple little pocket book of test papers which Dr. Oliver has been so instrumental in bringing forward. These urine test papers are very simple, and, as a rule, give a correct indication of the condition of the urine, but they are very little known, comparatively speaking, and consequently very little used. They are probably not altogether quite so reliable as the former method of urine testing, but we doubt not that the author of this little work will not remain idle in the matter, but will endeavour to, and will probably be successful in, bringing the testing of urine by papers to perfection.

ONE of the first and most obvious results of growth of population is the starting of literary ventures in the shape of newspapers and periodicals. We recently referred to this fact as connected with medical journalism in Australia. This week, the first number of a medical journal has reached us from another of our dependencies, South Africa. Like all beginnings, it is a small one, but it is nevertheless an evidence of enterprise among colonial brethren which affords us pleasure to notice and to encourage. Dr. Hartley, the editor, has launched his bantling with the usual discouragements, in consequence of which he begs that the first number may not be taken as a fair specimen, the reason for which he thus epitomises:—"In some cases our friends did not promise, in a few they did not reply, and in others they have promised but have not performed." It may afford our *confrères* a crumb of consolation if we assure him that before the end of a year he will have become as accustomed to them as to the payment of his printer's bill.

We congratulate Dr. Graham Brown on the appearance of a second edition of his "Medical Diagnosis" (Edinburgh: Bell and Bradfute), in about a year after the issue of the first. Short as this time is, the author has found it desirable to make a few changes, and he has added a considerable amount of new material. The additions relate to the general state of the patient—the symptomatology—the diseases of the alimentary system, and instrumental diagnosis. The engravings of Ziemssen's motor points now becoming familiar are inserted, and there are two photographs of drawings of ophthalmoscopic images. The laryngoscopic section is perhaps the weakest, being compiled almost entirely from a single writer—woodcuts included. The significance of pepton and the mode of its separation from albumen are briefly and clearly stated, as are a number of other points in this department. For the estimation of hæmoglobin Dr. Brown prefers Gower's method, gives an engraving of the instrument required, and directions for its use. The bacillus of anthrax is figured after Koch, and we suppose in a future edition he may add that of tubercle.

THE first edition of Martindale and Westcott's Extra Pharmacopœia having been exhausted in a few weeks, the second edition has now made its appearance without great loss of time. In addition to the matter contained in the first edition, the present issue contains accounts of a number of new drugs and preparations, a therapeutic index, and a number of references to current literature. We note but few omissions in the main body of the work. Ichthyol, however, a new preparation introduced by Unna, of Hamburg, as a remedy of value in rheumatism and skin diseases, finds no place in the list. Perchloride of mercury, although an official preparation, has, by the labours of Koch, had a new place assigned to it, viz.—that of the most powerful antiseptic, and should have been mentioned, to say nothing of ethereal oil of mustard (Koch), turpentine, atropia, &c. (Rossbach). The references to current literature are meagre, and are mainly confined to a few British weeklies. This is really the weakest part of the work. Notwithstanding the minor deficiencies the work is well worthy of the success it has attained, and is indispensable to anyone who is desirous of keeping up to the times.

THE fourth volume of the Index Catalogue of the United States Surgeon-General's Library has just reached Europe, and it includes all subjects, from the beginning of letter E to "Fizes." This magnificent work—probably the greatest medico-literary undertaking of any nation, or in any language—represents the analysis of 1,926 volumes, 3,885 pamphlets, 12,861 subject titles, and nearly 50,000 articles

in periodicals. Selecting a few headings from a multitude, we find in this volume an exhaustive catalogue of the literature of the ear, the eye, fever, education (medical), excisions, electricity (medical), extremities (diseases and injuries), embryology; and we find great difficulty in conceiving how the work of tabulation of the literature of these subjects alone could have been performed within any reasonable period by any organisation. Dr. Billings—the distinguished head of the Libraries Department—will achieve literary immortality for his labours in connection with this work, for it is very unlikely that any other nation will seek to compete with the United States in the publication of a rival work of this class, and still more unlikely that—if it did—any nation would produce so splendid a monument of literary research. The four volumes now published contain reference to 25,000 volumes, 27,500 pamphlets, and 150,000 journal articles. It is needless to say that any public library in the world which lacks the Index Catalogue is imperfect in an important respect.

THE author of "Hints on Sickness," will certainly not enhance his reputation by the issue of such works as this. Mr. Burdett has for some time past been honourably known as an enthusiast in the cause of Hospital Reform, and it is but fair to assume that many of the improvements in this direction, which have been steadily taking place of late, are the indirect results of his energetic advocacy and trenchant exposures. We understand, however, that his books were not a commercial success, and for this reason we presume he has gone in for a new departure in his "Hints on Sickness," and has allowed advertisers to puff their own goods in author's type, "out of their fulness of knowledge" (Burdett), one of them even has been good enough of his fulness to state that they "are sold by patent medicine dealers in all parts of the world." The author has, moreover, an appendix of a few Hospital advertisements, which he prefaces with a most objectionable note, to the effect that "whereas absence from this appendix conveys no reflection upon a charity; yet to his best knowledge and belief, funds entrusted to the managers of those institutions which do appear therein (i.e., those who were found willing to pay for the statement), will be laid out to the best advantage." The logic may be worth so much £ s. d. to Mr. Burdett, but is scarcely worthy so staunch a reformer as the "Founder of the Home Hospitals Association."

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, January 23rd:—St. Bartholomew's Hospital Reports, Vol. XIX. On Bedside Urine Testing, by G. Oliver, M.D. (2nd edit.). The Parents' Medical Note-book, by A. D. Walker, M.D. Refraction of the Eye, by G. Hartridge, F.R.C.S. The Pedigree of Disease, by Jonathan Hutchinson, F.R.C.S. *The Liverpool Medico-Chirurgical Journal*, Vol. VI. Manual of Practical Materia Medica and Pharmacy, by W. Whittle, M.D. Microscopical Morphology of the Animal Body in Health and Disease, by C. Heitzmann, M.D. The Different Aspects of Family Phthisis, by R. E. Thompson, M.D. A Text-book of the Principles of Physics, by G. Jaeger, M.D. Medical Fashions, by E. T. Tibbits, M.D. The Bladder during Parturition, by J. Halliday Croom, M.D. Porro's Operation, by Clement Godson, M.D.

Medico-Parliamentary.

HOUSE OF COMMONS.—FRIDAY, FEB. 22ND.

THE MEDICAL SERVICE IN EGYPT.

In reply to Sir H. Verney, Lord Hartington stated that the medical service for the expedition had been locally arranged. The Army Medical Corps in Egypt had been strengthened by a battalion of sixteen non-commissioned officers and men.

THE PATHOLOGY OF CHOLERA.

Dr. Cameron asked the President of the Local Government Board whether, in consideration of the exceptional importance of accurate knowledge as to the nature and causes of cholera, he would communicate with the Foreign Office as to the possibility of presenting to Parliament

translations of the Reports of the Commissions recently sent out by M. Pasteur and Dr. Koch to Egypt and India to investigate the pathology of that disease.

Mr. G. Russell said that the Local Government Board had communicated with the Foreign Office, and the Reports referred to would be printed and laid on the table.

HOUSE OF COMMONS.—MONDAY, FEB. 25TH.

CASTOR OIL AS A PUNISHMENT.

Dr. Cameron asked the Vice-President of the Council whether it was a fact that in Lochgoilhead Public School, castor oil poured down the throat, unmeasured, from a bottle, had habitually been administered to children as a punishment; and whether, in the interests of public education, he would order an investigation into the administration and discipline of the school.

Mr. Mundella said it was a fact that castor oil had been used in this school; not, however, as a punishment, but as a deterrent (much laughter). He could only say that he regarded its use, on any pretext, as wholly unwarrantable and reprehensible.

Lord R. Churchill.—Not under any pretext? (Renewed laughter.)

Indian Medical Service.—The following is a list of successful candidates at the competitive examinations during the present month:—

	Marks.		Marks.
1 Walsh, J. H. T.	2564	4 Fink, G. H.	2071
2 Hendley, H.	2110	5 Alpin, W. G. P.	2040
3 Banatvala, H. G.	2102		

Twenty-one candidates competed for five appointments; all were reported qualified.

College of Physicians in Ireland.—At the February examinations the following gentlemen obtained the licences in Medicine and Midwifery of this College:—

Medicine.

Delahunt, William Patrick.	Peet, Francis Fitzmaurice.
Finlay, Sinclair.	Price, William Thomas.
Hazleton, Edward Benjamin.	Roe, Francis Christian.
Manning, Nathaniel S.	Smith, Ventry Alexander John.

Midwifery.

Brown, Henry Edward.	Manning, Nathaniel S.
Digby, Cecil Arthur.	Peet, Francis Fitzmaurice.
Finlay, Sinclair.	Smith, Ventry Alexander John.
Hazleton, Edward Benjamin.	

The undermentioned has been admitted a Member:—

Bourke, George Dean.

St. Thomas's Hospital.—The following appointments have been made at this hospital:—House Physicians: Green, C. D., M.R.C.S., L.R.C.P.; Hull, Walter, M.B., M.R.C.S., L.R.C.P. Non-resident House Physician (re-appointed): Orford John M.R.C.S., L.R.C.P. Assistant House Physician: Tomson, W. B., M.B., M.R.C.S., L.R.C.P. House Surgeons: Caiger, F. F., M.B. B.S., M.R.C.S., L.R.C.P.; Johnston G. D., M.R.C.S., L.R.C.P. Assistant House Surgeon: Sheppard, W. J., M.B., M.S., M.R.C.S., L.R.C.P. Resident Accoucheur: Jones, W. Wansbrough, M.A., M.B., M.R.C.S. Clinical Assistant in the Special Department for Diseases, of the Skin: Robinson, H. B., M.R.C.S., L.R.C.P.

Notices to Correspondents.

65 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LEAVE OF ABSENCE FROM DISPENSARY.

MEDICUS asks whether an dispensary medical officer can leave his district for a day or two in charge of a thoroughly qualified medical man without first obtaining permission from the dispensary committee? Does he incur any risk in doing so?

[Strictly speaking, he cannot absent himself for an hour under any circumstances without leave previously obtained, but it is quite usual to take brief leave, care being taken to notify departure to the Hon. Sec. of Committee, and to make proper provision for performance of duty during absence.—ED.]

DR. TRAVERS.—Should the same principles be observed in this

instance as were taken to direct the authorities the last time the subject was discussed, the result will necessarily be disastrous to the wishes of a large majority. There is, however, no certainty of anything of the kind. The Secretary will be present.

NO CURE, NO PAY.

WE were irresistibly reminded of the trade-mark of certain sweeps and chimney-pot professors who stick outside of their houses "No cure, no pay," on receiving a few days ago the following advertisement for insertion in our columns:—

"The Radical Cure of Epilepsy. No fee whatever is charged in case of non-success. For particulars apply to —."

Although our publisher, by virtue of his superior judgment, declined the cash proffered, we give the above portion of said advertisement gratuitously, simply substituting for the part deleted that the epileptic curer's intentions are only equalled by his impudence.

MR. SHUTTLEWORTH.—Bebertia is obtained by a somewhat complicated process from the powdered bark of bebeeru, the *Nectandra Rodiazi*. "The sulphate of beberia" is not very soluble; it requires about 80 parts of water for solution.

S. E.—A moderately strong purgative seems to be required; but if this should not be resorted to with success, care should be taken against any attempts to force matters for a time.

ARMY MEDICAL EXAMINATIONS.

INQUIRER asks: (1) If any medical paper publishes the questions given on paper at the last Army Medical Examinations; (2) If we are aware of the number of candidates who competed for appointments; and (3) If it is a fact that Irish candidates are unfairly treated at the Army Examinations?

[1. The papers are generally to be found in one or other of the medical weeklies; sometimes (if we can find room) in this Journal. The questions set at each examination for the last few years are also given in a little book by Dr. Leask, entitled "Examination Questions." 2. The number of competitors is not given in the published returns, but can be found subsequently in the reports of the examiners to the General Medical Council. 3. We have no sufficient reason at present to make such a charge.—ED.]

MR. SYLVESTER.—It is not at all a usual occurrence for one practitioner to seek the privilege of attending a patient whom he knows to be under the care of a neighbouring medical man. We should prefer to think you must be in some way mistaken as to the facts; but if they are really as you state them there is absolutely no excuse for the conduct you complain of.

NITRO-GLYCERINE.

J. F. S. asks: How is nitro-glycerine used in angina pectoris; and is it prescribed in spasm after extreme nervous exhaustion, and how and where he can procure it? Where can he get the best account of its administration and curative effects?

[Nitro-glycerine is best administered in Martindale's tablets, which can be obtained at any respectable chemist's. Each tablet or lozenge contains 0.01 of a minim; and it is believed that they relieve cardiac spasm by relaxing the muscular coats of the capillaries. One should be taken every twenty minutes until relief be obtained. If taken too frequently they are apt to cause headache from relaxation of the cerebral vessels. Murrell's essay gives a good account of the matter.—ED.]

ATTENDANCE ON CONSTABULARY (IRELAND).

P. McN. asks whether he is bound to attend the family of a constable under the following circumstances: The constable lives at a protection post in the district of which he is the medical attendant. He keeps his wife and family at a town six miles distant and not in his district. Querist was sent for, a few days ago, to see the child in whooping-cough, but though it was explained to the messenger that querist did not consider himself bound to attend, he nevertheless telegraphed to one of the medical men in the town where the child lived to look after it for him. Querist was subsequently telegraphed for, and on this occasion wrote to the constable stating that he was advised he had no claim on his attendance, unless his family lived with him in barracks or within the limits of his district. "1. Was I correct in this? 2. Have I any redress against this constable for the services rendered by neighbouring medical practitioner at my expense."

[1. Quite correct. You are not liable under any circumstances to attend outside your district. 2. You might recover the fee, but we doubt that it is worth your while.—ED.]

DR. J. H. C.—Too late for present issue.

MR. T. C. C.—See reply to Dr. J. H. C.

PAYMENT OF DISPENSARY SUBSTITUTES.

T. G. B. H.—Boards of guardians are to determine the amount of remuneration, if any, to be paid to a temporary substitute, therefore may refuse to pay such substitute, no matter what the cause of absence of medical officer may be; but if the substitute has been retained by the honorary secretary of the dispensary committee, or if his appointment as *locum tenens* has been recognised or confirmed by the committee or its responsible officer, then the committee is liable to pay as a matter of simple contract, even though the board of guardians should refuse to do so. The substitute must be paid if the "medical officer be temporarily incapacitated by illness or other cause," so that a summons to assizes would be a good and sufficient reason for his absence, and for appointment of a *locum tenens*. See Article 22, Dispensary Regulations, page 262, Irish Medical Directory. Of course there can be no claim for payment unless the *locum tenens* has been appointed, or his appointment confirmed by the dispensary committee.

Meetings of the Societies.

WEDNESDAY, FEBRUARY 27TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Flower, On the Principal Types of the Human Species.

HUNTERIAN SOCIETY.—At 8 p.m., Mr. Clement Lucas, On Injuries to the Kidney.—Mr. Poland, On a Case of Acute Suppuration of the Hip and Elbow Joints.

THURSDAY, FEBRUARY 28TH.

ROYAL INSTITUTION.—At 3 p.m., Professor Tyndall, On the Older Electricity.

FRIDAY, FEBRUARY 29TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Flower, On the Principal Types of the Human Species.

ROYAL INSTITUTION.—At 8 p.m., Professor Hughes On the Theory of Magnetism.

CHARING CROSS HOSPITAL MEDICAL SOCIETY.—At 8 p.m., Mr. H. Montague Murray, On the Value of Phrenological Theories.

MEDICAL TEMPERANCE ASSOCIATION.—At 4 p.m., in the rooms of the Medical Society of London, Dr. Norman Kerr, On the Dalrymple Home.—Specimens of Non-Alcoholic Tinctures will be exhibited.

Vacancies.

Birmingham General Hospital.—Resident Medical Officer. Salary, £180, with board and residence. Applications to the House Governor by February 28.

Kent Hospital.—Physician on the Staff. Applications to the Secretary at the Hospital, Canterbury, y March 22.

Appointments.

FINLAY, the Rev. H., M.D., Health and Government Medical Officer for the District of Ravenswood, Queensland. Also a J. P. for the Colony of Queensland.

ILMS, A. E., L.R.C.P. Ed., M.R.C.S., Medical Officer to the Workhouse, Taunton Union.

LOCKWOOD, H., M.R.C.S., Assistant House Surgeon to the Public Hospital and Dispensary, Sheffield.

MADDISON, W. T., M.B., Assistant Medical Officer at the Darenth Asylum for Imbecile Children.

MAQUIER, E., M.D. Lond., M.R.C.P., Demonstrator and Assistant Lecturer on Pathology in the Owens College, Victoria University.

NEVILLE, M. O'B., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer to Ballineen Dispensary District, Co. Cork.

SCOT-SKIRVING, R. M.B., M.Ch. Ed., Resident Medical Superintendent to Prince Alfred Hospital, Sydney.

TOMKINS, A. W., M.D. T.C.D., L.R.C.S. Ed., Medical Officer for the Leamington District of the Warwick Union.

VIOLETTE, W. B., M.B., M.Ch. Glas., Resident Medical Officer to the Sydney Hospital.

WILSON, J. S., M.D. M.Ch. Glas., Government Medical Officer for the District of Wilcaunia, New South Wales.

Births.

HARRISON.—February 23, at Hastings, the wife of R. Charlton Harrison, L.R.C.P., M.R.C.S., of a son.

WARD.—February 17, at 1 Eblana Terrace, Dublin, the wife of Surgeon-Major E. C. B. Ward, F.R.C.S.I., A.M.D., of a son.

WYSE.—February 17, at 10 Goldsmith Terrace, Bray, the wife of George H. Wyse, L.R.C.S., L.R.C.P., of a daughter.

Marriages.

GOOD—BOWER.—February 23, at the parish church, St. Neots, Hunts, D'Arcy Frederick T. Good, F.R.C.S., of St. Neots, to Mary, younger daughter of the Rev. A. Bower, of Calster, Lincolnshire.

TOWNSEND—MAC MULLEN.—February 21, at St. Nicholas Church, Cork, Edmund Townsend, Surgeon-Major A.M.D., to Frances Josephine, youngest daughter of J. W. Mac Mullen, Clontymon, Cork.

Deaths.

BULL.—February 13, at Shenley House, Louisa Jane, the beloved wife of William H. Bull, Surgeon, St. Oswald's House, Stony Stratford, aged 27.

BUSHNAN.—February 17, after a lingering illness, John Stevenson Bushnan, M.D., &c., aged 78.

CARMICHAEL.—February 17, at Mentone, William Carmichael, M.D., late Staff-Surgeon R.N., aged 47.

GOLDSBRO.—December 20, at Parnell, New Zealand, Charles Field Goldsbro', M.D. & J.P., late of Trelystan, Montgomeryshire.

HICKINBOTHAM.—February 22, at 26 Broad Street, Birmingham, James Hickinbotham, M.D., aged 44.

MALASSEZ.—February 21, at 1 Bloomfield Terrace, Dundrum, Sebastian Malassez, Esq., Surgeon.

SCOTT.—February 10, at Shrewsbury, Ebenezer Samuel Scott, M.B. C.M. Ed., aged 31.

SEATON.—February 19, at Oxford Street, Nottingham, after a short illness, Florence Ann, wife of Dr. Seaton, aged 34.

TAYLER.—February 21, at Lovemead House, Trowbridge, Sarah Elizabeth (Beale) Tayler, the wife of G. C. Tayler, M.D., aged 54.

THOMPSON.—February 20, at York House, Chelsea Road, Clapham, Zoe Gertrude, the only child of the late Alfred F. Thompson, of Hull, aged 7.

TONNERRE.—February 20, at Camden, Sidmouth, Dr. Charles Fabre Tonnerre, late of Calcutta.

BAILLIÈRE, TINDALL, & COX'S BOOKS.

* Any of the Books in this List can be obtained in Australia of their Agent, Mr. L. BRUCK, 35 Castlereagh Street, Sydney.

Anatomy. Text-book of Anatomical Plates, designed under the direction of Professor MASSE, with descriptive Text. By E. BELLAMY, F.R.C.S., Surgeon to Charing Cross Hospital; Examiner in Anatomy, Royal College of Surgeons. New edition, Steel Plates, price 25s., or hand-coloured, 50s.

"Undeniably the most beautiful plates we have."—*Lancet*.

"With these plates the student will be able to read up his anatomy almost as readily as with a recent dissection before him."—*Students' Journal*.

Anatomy. A Series of Movable Atlases of the Human Body, showing the relative positions of the several parts, by means of Superposed Coloured Plates, from the designs of Prof. G. J. WITKOWSKI, M.D.

* A Treatise accompanies each part by leading physicians and surgeons attached to the London Hospitals.

PART I.—Neck and Trunk. Price 7s. 6d.

PART II.—Throat and Tongue, showing the Mechanism of Voice, Speech, and Taste. Price 7s. 6d.

PART III.—The Female Organs of Generation and Reproduction. Price 7s. 6d.

PART IV.—The Eye and the Apparatus of Vision. Price 7s. 6d.

PART V.—The Ear and Teeth. The Mechanism of Hearing and of Mastication. Price 7s. 6d.

PART VI.—The Brain (Cerebrum, Cerebellum, and Medulla Oblongata) and Skull. Price 7s. 6d.

PART VII.—The Male Organs of Generation. Price 7s. 6d.

PART VIII.—The Skeleton and its Articulations, showing the Bones and Ligaments of the Human Body and Limbs. Price 7s. 6d.

PART IX.—The Hand (Bones and Muscles). Price 7s. 6d.

* No such simple, reliable, and comprehensive method of learning the several parts, positions, and functions of the body has hitherto been attempted; the entire Series being unique, will be most valuable to the Teacher, the Student, and to all who wish to become acquainted with the anatomy and physiology of the human economy.

Anatomy. The Pocket Gray, or Anatomist's Vademecum. Compiled specially for Students from the works of Gray, Ellis, Holden, and Leonard. Fourth thousand. Price 2s. 6d.

"A marvellous amount of information has been condensed into a remarkably small space."—*Medical Press*

Anatomy. Schematic Anatomy; a new, easy, and more certain method of treating the Association and Schematic Arrangement of Structural Details of Human Anatomy. By WILLIAM P. MEARS, M.B., Professor of Anatomy at the University of Durham. Profusely illustrated. Price 7s. 6d.

"The aim of the work is decidedly good. . . . It is evidently the result of much trouble and thought."—*Lancet*.

Artistic Anatomy. Anatomy of the External

Forms of Man, designed for the use of Artists, Sculptors, &c. By Dr. J. FAU. Used at the Government School of Art, South Kensington. Twenty-nine plates. Folio; price, plain 21s., coloured 42s.

Artistic Anatomy. Elementary Artistic Anatomy of the Human Body. From the French of Dr. FAU. With English Text. Used at the Government School of Art, South Kensington. Price 5s.

Brain. The Brain and Diseases of the Nervous System. 2 vols. By T. STREICH DOWSE, M.D., F.R.C.P. Ed., formerly Medical Superintendent of the Central London Sick Asylum.

VOL. I.—Syphilis of the Brain and Spinal Cord, showing the part which this agent plays in the production of Paralysis, Epilepsy, Insanity, Headache, Neuralgia, Hysteria, and other Mental and Nervous Derangements. Second edition, illustrated, price 7s. 6d.

VOL. II.—Neuralgia: its Nature and Curative Treatment. Price 7s. 6d.

Burmah. Our Trip to Burmah, with Notes on the Ethnology, Geography, Botany, Habits, and Customs of that Country. By Surgeon-General GORDON, C.B., M.D., Physician to the Queen. Illustrated with numerous Photographs, Maps, Coloured Plates, and Sketches in gold by Native Artists. Price 21s.

"We lay down this book impressed with its many beauties, its amusing sketches and anecdotes, and its useful and instructive information of that comparatively unknown country."—*The Times*.

"A wonderful book, full of interest, instruction, and amusement."—*Saturday Review*.

Bronchitis. Chronic Bronchitis: its Forms and Treatment. By J. MILNER FOTHERGILL, M.D. Edin., M.R.C.P. Lond. Price 4s. 6d.

"It bristles with valuable hints for treatment."—*British Medical Journal*.

"The pages teem with suggestions of value."—*Philadelphia Medical Times*.

Case-Books. Students' Case-book. For recording hospital cases as seen, with full instructions for methodising clinical study. By GEORGE BROWN, M.R.C.S., Gold Medallist, Charing Cross Hospital, late Demonstrator of Anatomy, Westminster Hospital. Third thousand, price 1s., cloth limp.

Children. The Diseases of Children, their History, Causes and Treatment. By C. E. ARMAND SEMPLE, B.A., M.B. Cantab., M.R.C.P. Lond., Physician to the North-Eastern Hospital for Children. Price 6s.

Cholera. Cholera: how to Prevent and Resist it.

By Professor VON PETTENKOFER, University of Munich, President of the Sanitary Department of the German Empire; and THOMAS WHITESIDE HIME, A.B., M.B., Medical Officer of Health for Bradford. Second edition. Illustrated with woodcuts and diagram. Price 3s. 6d.

Clinical Charts for Recording the Range of Temperature, Pulse, Respiration, History, Progress, and Treatment of Cases, for use in Hospitals and in private practice. By E. W. MOORE, M.D., M.R.C.P. Price 1d. each, 9d. per dozen, or mounted, similar to a blotting-pad, in 50, 3s. 6d.; 100, 7s.

Deafmutism. On the Education of Deaf-Mutes by

Lip-Reading and Articulation. By Professor HARTMANN. Translated by Dr. PATTERSON CASSELLS. Price 7s. 6d.

"The instruction of deaf-mutes is here rendered easy."—*Athenæum*.

"Contains so much real information that we can honestly recommend it to anyone seeking for knowledge."—*The Lancet*.

Diagnosis. The Physiological Factor in Diagnosis.

By J. MILNER FOTHERGILL, M.D., M.R.C.P. Lond., Physician to the City of London Hospital for Diseases of the Chest. Second Edition, price 7s. 6d.

"This is an exceedingly clever and well-written book, put together in a very plain, practical, and taking way."—*Edinburgh Medical Journal*.

Dictionary of German Terms used in Medicine.

By GEORGE R. CUTTER, M.D. Price 6s. 6d.

"An original work of considerable merit, and of absolute necessity to the student of German medical literature."—*New York Medical Journal*.

Domestic Medicine. Handbook of Popular Medi-

cine for family instruction; for colonists and others out of reach of medical aid. By G. H. NAPHY, A.M., M.D. With movable plate, and 100 illustrations. Price 7s. 6d.

"We have rarely read any form of domestic medicine so simple, yet reliable."—*Public Opinion*.

Ear. Text-book of the Diseases of the Ear and

adjacent Organs. By Professor POLITZER, of Vienna. Translated by JAMES PATTERSON CASSELLS, M.D., Consulting Physician to the Glasgow Ear Infirmary. 800 pages, with 257 original illustrations. Price 21s.

"The work of a recognised master."—*British Medical Journal*.

"Will take rank as the standard book of reference for years to come."—*Medical Times*.

London: BAILLIÈRE, TINDALL, & COX, 20 King William Street, Strand.

Sydney: L. BRUCK, 35 Castlereagh Street.

A SELECTION OF WORKS, *continued*,

Ear. On Diseases of the Ear, their Diagnosis and Treatment. By OREN D. POMEROY, M.D., Surgeon to the Manhattan Eye and Ear Hospital, New York, &c. In one handsome 8vo. volume of over 400 pages, profusely illustrated, cloth. Price 12s.

Etiquette. A few Rules of Medical Etiquette. By a L.R.C.P. Lond. Price 1s.

Examinations. A Guide to the Examinations at Royal College of Surgeons of England for the Diplomas of Member and Fellow, with Examination Papers. By F. J. GANT, F.R.C.S. Author of the "Science and Practice of Surgery." Fourth Edition, revised and enlarged. Price 4s. 6d.

"In truth a most useful Guide to the Examinations."—*Guy's Hospital Gazette*.

Examinations. Examination Questions on the Medical Sciences, including the Army, Navy, and University Examinations. Selected and arranged by JAMES GREGG LEASK, M.B. Aberdeen. Second Edition. Price 1s. 6d.

"Dr. Leask's questions are particularly suitable for pure examination study. Students should test themselves thereby."—*British Medical Journal*.

Eye. The Cure of Cataract and other Eye Affections. By JABEZ HOGG, M.R.C.S., Consulting Surgeon to the Royal Westminster Ophthalmic Hospital. Third edition. Price 2s. 6d.

Eye. The Functions of Vision and its Anomalies. By Dr. GIRAUD-TEULON, Member of the Académie de Médecine, Translated by LLOYD OWEN, F.R.C.S.I., Surgeon to the Birmingham and Midland Eye Hospital, Ophthalmic Surgeon to the Free Hospital for Sick Children, Birmingham. Illustrated, price 5s.

Fever. On the Endemic Hamaturia of Hot Climates, caused by the presence of Bilharzia Hamaturia. By F. H. H. GUILLEMIARD, M.A., M.D., F.R.G.S. Price 2s.

Food. Food; its Varieties, Chemical Composition, Nutritive Value, Preparation, Preservation, Adulterations, &c. By the late Dr. LETHÉBY. Second edition, enlarged, price 5s.

"Dr. Lethéby's position and authority on the subject of food is so pre-eminent, that a book from his pen is above criticism."—*Lancet*.

"Either as a text-book for schools or as a household guide, it is excellently adapted."—*Public Opinion*.

Forensic Medicine. The Student's Handbook of Forensic Medicine and Medical Police. By H. AUBREY HUSBAND, M.B., F.R.C.S.E. Fourth edition. Price 10s. 6d.

Geology. Field Geology, with a Section on Paleontology. By W. H. PENNING, F.G.S., of H.M. Geological Survey, and A. J. JUKES BROWN, B.A., F.G.S. With woodcuts and coloured map. Second edition, revised and enlarged, price 7s. 6d.

"Others have taught us the principles of the science, but Mr. Penning, as an accomplished field geologist, introduces us to the practice."—*The Academy*.

Gynaecology. A Modern Manual of Diseases of Women. By H. MACNAUGHTON JONES, M.D., F.R.C.S., Examiner in Midwifery, Royal College of Surgeons. Profusely illustrated. Price 5s.

Gynaecology. A Manual of the Minor Gynaecological Operations and Appliances. By J. HALLIDAY CROOM, M.D., F.R.C.P., F.R.C.S.E., Lecturer on Midwifery and Diseases of Women at the Edinburgh School of Medicine. Second edition, with 12 plates and 40 woodcuts, price 6s.

Gynaecology. Lessons in Gynaecology and Obstetrics. By W. GOODELL, A.M., M.D., Professor of Clinical Gynaecology in the University of Pennsylvania. Second edition, with 92 illustrations, price 18s.

Hay Fever: its Causes, Treatment, and Effective Prevention; Experimental Researches. By CHARLES HARRISON BLACKLEY, M.D. Second edition, revised and enlarged, price 10s. 6d.

"A piece of real honest work, original and instructive."—*Lancet*.

Heart. An Essay on Fatty Heart. By Henry KENNEDY, A.B., M.B., Physician to the Whitworth Hospitals. Price 3s. 6d.

"We have no hesitation in recommending it as a most valuable contribution to the literature of the all-important subject of which it treats."—*Medical Press*.

Histology. Introduction to Practical Histology. By GEORGE THIN, M.D. Price 5s.

"No more valuable text book for the student will be found, nor one containing a greater amount of useful information."—*Medical Press*.

Hygiene. Short Lectures on Sanitary Subjects. By RICHARD J. HALTON, L.R.C.P., L.R.C.P. Ed., L.R.C.S.I., &c., Medical Officer of Health to Kells. Price 5s.

"A book well adapted to popular reading, and replete with sound knowledge promotive of good health and long life."—*Sanitarian*.

Hygiene. Lessons in Military Hygiene and Surgery, from the Franco-Prussian War. Reports prepared while on Special Service with the French Army in Paris, on behalf of Her Majesty's Government. By Surgeon-General GORDON, M.D., C.B., Hon. Physician to the Queen. Illustrated, price 10s. 6d.

"A treatise of exceptional merit, drawn from personal experiences in the greatest war of modern times."—*Army and Navy Gazette*.

Hygiene. A Manual of Sanitation; or First Help in Sickness and when Wounded. A pocket companion for officers and privates in the army or volunteer forces. By the same Author. Second edition, price, cloth, 2s. 6d., or cheap edition, paper wrapper, 1s.

"It is a most useful and practical manual, and, as the instructions are simple and reliable, it should be placed in the hands of officers and men alike."—*The Graphic*.

Hygiene. A Manual of Naval Hygiene, with Instructions and Hints on the Preservation of Health and the Prevention of Disease on board Ship. By JOSEPH WILSON, M.D., Medical Director of the United States Navy. Second edition, price 10s. 6d.

Impotence. On Sexual Impotence in the Male. By WILLIAM A. HAMMOND, M.D., Surgeon-General U.S. Army (Retired List). In one handsome 8vo. volume of nearly 300 pages. Cloth, price 10s.

Insanity. The Diagnosis, Classification, and Treat-ment of Insanity. A Manual for Students and Practitioners of Medicine. By E. C. SPITZKA, M.D., President of the New York Neurological Society, &c. In one handsome 8vo volume of nearly 425 pages, illustrated, cloth, price 12s.

"Original and painstaking, as everything is which Professor Spitzka undertakes."—*Medical Times*.

Kidneys. Bright's Disease of the Kidneys. By Professor J. M. CHARCOT. Translated by H. B. MILLARD, M.D., A.M. Revised by the Author, with coloured plates, price 7s. 6d.

"We doubt very much if there exists in the English language any monograph in which the various forms are so accurately and concisely described."—*Medical Press*.

Lunacy. Handbook for Attendants on the Insane; instructions for the management, artificial feeding, and mechanical restraint of the insane; legal documents required for their confinement, &c. By L. S. FORBES WINSLOW, M.B., D.C.L. Oxon., M.R.C.P., Lecturer on Mental Diseases, Charing Cross Hospital. Price 1s.

Materia Medica. Note-Book of Materia Medica and Therapeutics. By R. E. SCORESBY-JACKSON, M.D., F.R.S. Revised by ANGUS MACDONALD, M.A., F.R.S. Third edition, price 12s. 6d.

"A work we can recommend with the utmost confidence."—*Students Journal*.

Materia Medica and Pharmacy. A Text-Book for Medical and Pharmaceutical Students preparing for Examination. By W. HANDSEL GRIFFITHS, Ph.D., F.R.C.S., F.R.C.P. Ed. Edited by GEORGE F. DUFFEY, M.D. Dub., Fellow and Examiner K.Q.C.P., Examiner in Materia Medica, Queen's University, &c. Price 9s.

"A book of great value . . . a standard text-book."—*Edin. Med. Journal*.

"One of the ablest, if not the best, work on the subject in our language."—*Med. Press*.

Medical Laws. The Laws Relating to Medical Men. By JAMES GREENWOOD, Barrister-at-Law. Price 5s.

"We expect that it will meet with the success which it really deserves."—*Edin. Med. Journal*.

London: BAILLIERE, TINDALL, & COX, 20 King William Street, Strand.

Sydney: L. BRUCK, 35 Castlereagh Street.

from BAILLIERE, TINDALL, & COX'S CATALOGUE.

Microscopical Science. Studies in Microscopical

Science for the use of the Medical Profession, Students, and others interested in the progress of the Natural Sciences. Edited by ARTHUR C. COLE, F.R.M.S., assisted by eminent Microscopists. Vol. I. containing 53 plates in chromo-lithography. Cloth, price 27s. 6d. Half-bound morocco, 31s. 6d.

Mineral Waters. The Mineral Waters of Europe.

A complete Analytical Guide to all the Bottled Waters, and their Medicinal and Therapeutic Values. By Professor TICHBORNE, LL.D., F.C.S., President of the Pharmaceutical Society of Ireland, and M. PROSSER JAMES, M.R.C.P., Lond., Lecturer on Therapeutics, London Hospital, Physician to the Hospital for Diseases of the Throat. Price 3s. 6d.

"Such a book as this is simply invaluable."—*The World*.

"This admirable and concise hand-book meets a very pressing want."—*Athenæum*.

Obstetrics. Hints in the Obstetrical Procedure. By

W. B. ATKINSON, A.M., M.D., Obstetric Physician in the Howard Hospital, Philadelphia. Second edition. Price 4s.

Obstetrics. The Therapeutics of Gynæcology and

Obstetrics, comprising the Medical, Dietetic, and Hygienic Treatment of Diseases of Women. By W. B. ATKINSON, A.M., M.D. Third edition (in the press). Price 18s.

Osteology. Osteology for Students, with Atlas of

Plates. By ARTHUR TREHERN NORTON, F.R.C.S., Surgeon to, and Lecturer on Surgery at, St. Mary's Hospital. Atlas and Text in one volume, 7s. 6d.; in two volumes, 8s. 6d.

"The handiest and most complete hand-book of Osteology."—*The Lancet*.

Pharmacy. Latin Grammar of Pharmacy, for the

use of Medical and Pharmaceutical Students, with an Essay on Latin Prescriptions. By JOSEPH INCE, A.K.C.L., formerly Examiner and Member of Council, Pharmaceutical Society. Price 4s.

Pharmacy. A Treatise on Pharmacy. A Text-book

for Students, and a Guide for the Physician and Pharmacist. By EDWARD PARRISH. Fifth edition, revised by T. S. WIEGAND, F.C.S., with 300 illustrations, half-bound morocco, price 80s.

"There is nothing to equal Parrish's Pharmacy in this or any other language."—*Pharmaceutical Journal*.

Physiology. A Manual of Physiology. By E. D.

MAPOTHER, M.D., Professor of Physiology; formerly President Royal College of Surgeons, Dublin. Third edition, edited by T. F. KNOTT, Demonstrator of Anatomy, Royal College of Surgeons. Price 14s.

"As a storehouse of information, it is superior to any manual of its size with which we are acquainted."—*Dublin Journal of Medical Science*.

Physiology. A Student's Manual. By B. Thompson

LOWNE, F.R.C.S., Arris and Gale Lecturer, and Examiner in Physiology, Royal College of Surgeons of England. Fourth thousand, illustrated. Cloth, 4s. 6d.

Physiological Laboratory. Manual for the Physio-

logical Laboratory. By VINCENT HARRIS, M.D., M.R.C.P., Demonstrator of Physiology at St. Bartholomew's Hospital, and D'ARCY POWER, B.A. Oxon., Assistant Demonstrator. Third Edition, price 5s.

"The first edition was one of considerable merit, but the illustrations and additional chapters in the present volume have greatly increased its value."—*British Medical Journal*.

Physiological Chemistry of the Brain, based

throughout upon original researches. By J. L. W. THUDICHUM, M.D., F.R.C.P. Lond., President of the West London Medical-Chirurgical Society. Price 10s. 6d.

Plant Analysis. Quantitative and Qualitative.

By G. DRAGENDORFF, Professor of Chemistry and Pharmacy in the University of Dorpat. Translated by H. G. GREENISH, A.I.C. Price 7s. 6d.

Posology. Posological Tables: a Classified Chart,

showing at a glance the Dose of every Official Substance and Preparation. By HANDSEL GRIFFITHS, Ph.D., L.R.C.P. Fourth edition, price 1s.; or mounted on linen, rollers, and varnished, 3s. 6d.

Sewage. The Sewage Question: Reports upon the

Principal Sewage Farms and Works of the Kingdom, with Notes and Chemical Analyses. By the late Dr. LETHBRIDGE. Price 4s. 6d.

"These Reports will dissipate obscurity, and, by placing the subject in a proper light, will enable local authorities and others interested in the matter to perceive the actual truths of the question, and to apply them practically."

Sphygmograph. The Sphygmograph: its History

and Use as an aid to Diagnosis. By R. E. DUDGEON, M.D. Price 2s. 6d.

Surgery. The Science and Practice of Surgery,

being a Complete Text-book. By FREDERICK J. GANT, F.R.C.S., President of the Medical Society of London; Surgeon to the Royal Free Hospital. Second edition, illustrated by nearly 1,000 engravings, new and original, in 2 vols., price 81s. 6d.

With special chapters by

WM. ADAMS, F.R.C.S., Deformities.
ROBERT BARNES, M.D., F.R.C.P., Obstetrics.
MORELL MACKENZIE, M.D., The Throat.
F. A. MAHOMED, M.D., The Sphygmograph.
HY. POWER, F.R.C.S., Ophthalmic Surgery.
LAIDLAW PURVES, M.D., Aural Surgery.
C. S. TOMES, F.R.S., Dental Surgery.
SIR ERASMUS WILSON, F.R.S., The Skin.

"Gant's able and laborious work must be commended."—*The Lancet*.

"Does credit to the author's thorough surgical knowledge."—*British Medical Journal*.

"Will become one of the most popular Surgical Text-books in the English language."—*Medical Press*.

"A very complete and trustworthy guide to practice."—*Medical Times*.

Surgery. The Text-book of Operative Surgery.

From the French of Professors CLAUDE BERNARD and HUETIE. With 88 plates. Text edited and re-written by ARTHUR TREHERN NORTON, F.R.C.S., Surgeon to, and Lecturer on Surgery at, St. Mary's Hospital. Price, plain, 25s.; coloured, half-calf, 50s.

"Of the highest merit as a guide to operative surgery."—*Students' Journal*.

Therapeutics. Modern Medical Therapeutics. A

Compendium of recent Formula and Specific Therapeutical Directions, from the practice of eminent contemporary Physicians, English, American, and Foreign. Edited by G. M. NAPHEYS, A.M., M.D. Seventh edition, price 18s.

"The volume will supply what many practitioners are often anxious to possess for reference in the practice of their art."—*Glasgow Medical Journal*.

Therapeutics. Modern Surgical Therapeutics.

From the Practice of eminent contemporary Physicians and Surgeons, English, American, and Foreign. Edited by G. H. NAPHEYS, A.M., M.D. Seventh edition, price 18s.

"Of much value to the surgeon and general practitioner."—*New York Medical Journal*.

Therapeutics. The Principles and Methods of

Therapeutics. Translated from the French of ADOLPHE GUBLER, M.D., Professor of Therapeutics in the Paris Faculty of Medicine. Half-calf, price 18s.

Throat. Affections of the Throat and Larynx.

By ARTHUR TREHERN NORTON, F.R.C.S., Surgeon to St Mary's Hospital. Second edition, illustrated, price 6s.

"Short, simple, and thoroughly practical instruction."—*Medical Times*.

Transactions of Societies. Transactions of the

Academy of Medicine in Ireland. Vol. I. 1883. Edited by WILLIAM THOMSON, M.A., F.R.C.S., General Secretary, Med. 8vo, cloth, 414 pp., with numerous illustrations, price 14s.

Urine. The Urine: a Guide to its Practical Exa-

mination. By J. TYSON, M.D., Professor of Morbid Anatomy in the University, and President of the Pathological Society of Philadelphia. Fourth edition, with numerous illustrations, price 7s. 6d.

"We think it the most practically useful guide we have on the subject."—*Medical Record*.

Urinary Diseases. Diseases of the Bladder, Pros-

tate Gland, and Urethra. By F. J. GANT, F.R.C.S., Senior Surgeon to the Royal Free Hospital. Fifth edition, revised and enlarged, with numerous illustrations, price 12s. 6d.

Urinary Diseases. Genito-Urinary Diseases and

Syphilis. By FESSENDEN N. OTIS, M.D., Clinical Professor of Genito-Urinary Diseases in the College of Physicians and Surgeons, New York, &c. It forms a handsome 8vo volume of about 600 pp., cloth, price 18s.

Whooping-Cough: Its Pathology and Treatment.

Being the Prize Essay to which the Fothergillian Gold Medal of the Medical Society of London was awarded in 1882. By THOS. M. DULAN, F.R.C.S., L.R.C.P.E. Price 3s. 6d.

THE STUDENTS' AIDS SERIES.

Specially designed to assist Students in committing to memory and grouping the subjects upon which they are to be examined.

Aids to Anatomy. By GEORGE BROWN, M.R.C.S., Gold Medalist, Charing Cross Hospital. Eighth Thousand. Price 1s. 6d. cloth; 1s. paper wrapper.

"The little book is well done."—*Lancet*.

Aids to Botany. By C. E. ARMAND SEMPLE, B.A., M.B. Cantab., M.R.C.P. Lond., late Senior Examiner in Arts at Apothecaries' Hall. Third Thousand. Price 2s. 6d. cloth; 2s. paper wrapper.

Aids to Chemistry. By the Same Author.

PART I.—Inorganic; Non-Metallic Substances. Fifth Thousand, price 1s. 6d. and 1s.

PART II.—Inorganic; The Metals. 2s. 6d., 2s.

PART III.—Organic. Price, cloth 2s. 6d.; paper 2s.

PART IV.—Tablets of Chemical Analysis. Price 1s. 6d. and 1s.

Aids to Diagnosis.

PART I.—Semeiological. By J. MILNER FOTHERGILL, M.D., M.R.C.P. Lond. Price 1s. 6d. cloth; 1s. paper.

PART II.—Physical. By J. C. THOROWGOOD, M.D., F.R.C.P. Lond. Price 1s. 6d. cloth, and 1s. paper.

PART III.—What to Ask. By J. MILNER FOTHERGILL, M.D., M.R.C.P. Lond. Price 1s. 6d. cloth; 1s. paper.

"A mine of valuable information."—*Edinburgh Medical Journal*.

Aids to Examinations. Being Questions and Answers on Materia Medica, Medicine, Midwifery, Pathology, &c. By W. DOUGLAS HEMMING, F.R.C.S., and H. AUBREY HUSBAND, M.B., F.R.C.S. Third Thousand. Price 1s. 6d. cloth; and 1s. paper.

Aids to Forensic Medicine and Toxicology. By W. D. HEMMING, F.R.C.S.E., and H. AUBREY HUSBAND, M.B., F.R.C.S.E. Third Thousand. Price 1s. 6d. and 1s.

"We have no hesitation in recommending Mr. Hemming's book."—*Lancet*.

Aids to Materia Medica and Therapeutics. By C. E. ARMAND SEMPLE, B.A., M.B. Cantab., M.R.C.P. Lond.

PART I.—The Non-Metallic and Metallic Elements, Alcoholic and Ethereal Preparations. Third Thousand, 2s. 6d. and 2s.

PART II.—Vegetable and Animal Substances, 2s. 6d. and 2s.

PART III.—Tablets of Materia Medica. Price 1s. 6d. and 1s.

Aids to Medicine. By the same Author.

PART I.—General Diseases. Lungs, Heart, and Liver. Third Thousand. Price 2s. 6d. and 2s.

PART II.—The Urine, Kidneys, &c. Price 2s. 6d. and 2s.

PART III.—Diseases of the Brain and Nervous System. Price 1s. 6d. and 1s.

PART IV.—The Fevers, Skin Diseases, &c. (concluded). Price 1s. 6d. and 1s.

Aids to Obstetrics. By SAMUEL NALL, B.A., M.B., Cantab., M.R.C.P. Lond., Scholar in Natural Science, St. Bartholomew's Hospital, late House Physician and Resident Obstetric Assistant, St. Bartholomew's Hospital. Price 2s. 6d. cloth; 2s. paper wrapper.

Aids to Pharmacy. By C. E. ARMAND SEMPLE, B.A., M.B. Cantab., M.R.C.P. Lond. Cloth, price 2s. 6d.; paper wrapper, 2s.

Aids to Physiology. By B. THOMSON LOWNE, F.R.C.S., Examiner in Physiology, Royal College of Surgeons. Fourth Thousand. Complete in two parts at 2s. each, or bound in one vol. cloth, price 4s. 6d.

"Certainly one of the best of the now popular Aids Series."—*Students' Journal*.

Aids to Practical Physiology. By BRINDLEY JAMES, M.R.C.S. Price 1s. 6d. and 1s.

Aids to Physiological Chemistry. By J. L. THUDICHUM, M.D., F.R.C.P. Lond., President of the West London Medico-Chirurgical Society, formerly Lecturer on Physiological Chemistry, St. Thomas's Hospital. Price 2s. 6d. and 2s.

Aids to Psychological Medicine. By L. S. FORBES WINSLOW, M.B., D.C.L. Oxon. Price 1s. 6d. and 1s.

Aids to Public Health. By J. L. THUDICHUM, M.D., F.R.C.P. Lond. Price 1s. 6d. cloth, 1s. paper.

Aids to Surgery.

PART I.—By GEORGE BROWN, M.R.C.S. Price 1s. 6d. and 1s.

PART II.—1s. 6d. and 1s.

Aids to Rational Therapeutics. By J. MILNER FOTHERGILL, M.D., M.R.C.P. Lond. Double Part. Price 2s. 6d. and 2s.

Aids to Zoology. By MAJOR GREENWOOD, M.R.C.S., L.R.C.P., Honours in Zoology, University of London. Price 2s. 6d.

To the PROFESSION in AUSTRALIA, NEW ZEALAND, &c.

THE Conductors of this Journal beg to submit an ordinary Weekly copy of the *Medical Press and Circular* (ESTABLISHED 1838), for your approval and SUPPORT.

It is one of the oldest, and one of the most widely and influentially circulated of all the Medical Journals.

It is also the only one which devotes equal space to (Society Reports, Hospital Reports, &c., and to Contributors of Original Papers in) England, Ireland, and Scotland. It has special correspondents in France, Germany, Austria, &c.; and all matters of interest from Foreign sources are translated and reported.

The Subscription to the Colonies, post free per annum, is 23s. 6d.

HOARSENESS AND LOSS OF VOICE. (a)

By ARTHUR TREHERN NORTON, F.R.C.S.
Surgeon to St. Mary's Hospital.

(Continued from page 118.)

Hoarseness, or Aphonia, due to a fault of the muscles.—The muscles may be strained or fatigued, and unable to carry out their functions correctly, as in hoarseness from a high elevation of the voice in singing, or in loud public speaking; or in commanding, as officers upon a field day. Further, the muscles may be infiltrated by contiguous inflammations, or they may be the subject of rheumatism. By the history of the case we readily gather whether or not the muscles have been fatigued or strained, and the cause of the condition being removed, that is to say rest being employed, the voice will be soon recovered.

Infiltration of some of the muscles may be suspected when, after recovery from inflammation of any sort, the larynx is seen to be normal, but voice remains hoarse. The application of a blister the size of a two shilling piece to the region of the thyroid cartilage, and the use of galvanism, will prove curative very quickly.

Rheumatism of the intrinsic muscles of the larynx is very little understood; yet, I believe it to be of very common occurrence. I find it in persons who live on clay soils and damp districts, and who exhibit rheumatic pains in joints and other parts of the body. It may be best explained by the following cases:—A gentleman in the War Office was sent to me by Mr. Drew. He resided near Windsor. For six months his voice had a deep hoarseness, and it was a great trouble to him to speak; latterly he had become aphonic. The laryngoscope exhibited a normal larynx; there was no discoloration nor hypertrophy of the true cords. I applied the intermittent current to the neck in the neighbourhood of the

larynx. I never apply the current within the mouth or larynx, because I find it absolutely unnecessary. After two applications, with three days interim, a voice was produced, though very deep and hoarse. Mr. Drew, at my advice continued the treatment of galvanism, and the patient rapidly recovered.

Another case very similar you have recently had the opportunity of seeing in the throat department here. A man was sent to us by Mr. Parsons, of Wimbledon. His voice had been deeply hoarse for a year and a half, and when he came to the hospital he could scarcely produce any sound, so he spoke in a whisper. The larynx might be said to be normal. There was the barest discoloration of the true cords near the tubercle of the arytenoid cartilages. There was no evidence of an inflammatory condition of the larynx; there was no evidence of syphilis. He had been treated for syphilis; and for chronic catarrh with the usual inhalations, &c. He was completely cured by some half dozen applications of galvanism to the neck. A third case is one commonly met with in middle and upper class life. A lady from Surbiton, who suffered from rheumatism in the wrists, had lost her singing voice for the production of upper notes. Being a good singer she was in great distress. The larynx was quite normal. The singing voice was quite restored by some dozen applications of the battery. From time to time it fails, but one or two applications of galvanism are now sufficient.

Loss of Voice due to Some Fault in the Nerve Supply.—The laryngeal nerves may be affected through the centre, as in bulbar paralysis; or locally, through compression by inflammatory exudations; or by aneurism; or by cancerous or other growths in the immediate neighbourhood, such as those involving the œsophagus, thyroid body, glands of the neck, or mediastinum.

Bulbar Paralysis.—There is at the present time attending the Throat Department of the hospital, a man of about 65 years of age, suffering from this form of paralysis, or as it is called, labio-glosso-laryngeal paralysis. It is a disease affecting the nuclei of the hypoglossal, facial, spinal accessory, and pneumogastric nerves and from thence often spreading down the cord. The

(a) Delivered at St. Mary's Hospital, London.

tongue being affected, there is labour in its movements, and difficulty in the production of labial and dental consonants. Often difficulty in swallowing, the morsel being forced from the pharynx again into the mouth, or into the nose; dribbling of the saliva, which is increased in quantity. The larynx being affected, it is labour to speak, and as both sides of the larynx gradually become paralysed, inspiration becomes noisy from obstruction, in some cases requiring tracheotomy. If the disease extends down the cord there is diminution of power in arms, and then in other parts. Regardless of treatment this disease terminates fatally, though it may last over many years.

Local paralysis is almost invariably unilateral, and it is generally the recurrent laryngeal nerve which is affected. The symptoms are precisely the same, whether that nerve is compressed by exudation or aneurism or by cancerous or other growths, though the prognosis is different. The recurrent laryngeal nerve supplies all the intrinsic muscles of the larynx, except the cricothyroid, and partly the arytenoideus. If then, the recurrent laryngeal be affected, those two muscles will be able to act. The cricothyroid is the tensor of the vocal cord, and therefore the cord of the affected side is always held in a state of tension. The arytenoid partly dilates the glottis, and therefore the cord of the affected side is not straight, but slightly curved away from the central line.

The voice is hoarse because the two cords are not adapted for the same pitch, and it is uncertain, though many words may be produced in the natural voice. Respiration is normal, unless excited by exertion, when inspiration is accompanied by stridor.

When, by means of the laryngoscope, this condition of the cords is detected, the diagnosis of unilateral paralysis is clear, and it remains to find out only the cause. Should it be contiguous inflammation, there will be a history, and other signs readily distinguished, and the prognosis is that the paralysis will disappear as the inflammatory exudation becomes absorbed.

If cancer or tumour in the region of the neck be the cause, the growth will, in all probability, be recognised by manipulation. If in the glands of the mediastinum there is generally some constitutional sign of the disease, and if aneurism, the signs of aneurism may be there.

It is not uncommon that the alteration of the voice is the first sign pointing to the presence of an aneurism, and at a time when signs of aneurism are insufficient to be confidently detected. Aneurism is proved negatively by the exclusion of all other causes of compression of the recurrent laryngeal nerve.

Aphonia a Mental Condition, or Hysterical Aphonia.—Hysterical aphonia is unaccompanied by any local change or disease, and is diagnosed by the laryngoscope without any difficulty. Among the causes are constitutional debility, circumstances of marriage, sterility, disorders of menstruation, and other circumstances conducive to emotion.

I have never seen a case in a male, but have met with it in all ages in the female, even up to 70 years.

Symptoms.—The aphonia is always complete. Never hoarseness; because it is impossible to simulate hoarseness. It comes quite suddenly without any history or recognised cause, though, if in a young female, it is generally associated with abnormal catamenia. There is no sign or symptom of laryngeal disease; the laryngoscope generally exhibits an anæmic larynx; other signs of hysteria may or may not be present. It is commonly the case that patients with hysterical aphonia occupy themselves in their ordinary way with their usual vigour, and perhaps talk a great deal more than is their custom, though in a whisper.

If, when examining with the laryngoscope, the patient is told to make the sound Ah! Ah! the true cords will probably not be moved, and sounds will be whispered. Sometimes the patient will actually sound the expression ignoring the fact that the sound made is a veritable

proof of ability to talk out loud. In such a case the hysteria is unmistakably diagnosed.

Another proof of hysteria is this, if when, with a healthy larynx, the patient endeavours to make the sound the true cords do not come into contact, it is not paralysis, but the will of the patient that they should not approach, for no form of paralysis occurs in which the cords are widely separated and cannot approach each other.

Another proof of hysteria is the existence of complete aphonia with no evident disease within the larynx, for any cause of complete aphonia, with the exception of a fault of the nerves must be accompanied by marked change within the larynx.

Treatment.—Search out and remedy the cause. If the catamenia be wrong, regulate it. Local treatment is unnecessary, but it is a good plan to employ galvanism—firstly, with the object of making the patient believe that some effort is being made to restore the voice; and secondly, with the object of giving the patient a fair excuse for recovering her voice. Further, galvanism is often a further proof of the case being one of hysteria.

Some of you may recollect a patient under my care whom, a short time ago, I galvanised; she was requested to say immediately she felt the current. For some few minutes she held the handles without the current being allowed to pass, and was then questioned as to whether she yet felt it, to which she whispered No. Suddenly, a rather strong current was switched on, when the patient called out "Oh! I feel it!" She was then informed that galvanism had quickly returned to her her voice.

Galvanism applied to the neck in these cases as a direct local treatment is useless, because there is no local disease, and I may remark that some patients would bear any pain rather than speak, no matter how cruelly applied.

TUMOURS OF THE LARYNX.

Tumours are malignant and non-malignant, and affect the voice by obstructing the action of the cords, the breathing by decreasing the calibre of the breathing space. They can of course be at once recognised by the laryngoscope. By the stethoscope they may be sometimes heard to move, and they often produce a dry cough by irritating the larynx. The tumour may be sometimes grasped by the cords, and sometimes avoided, in which case the voice may be irregular, normal, or absent, a whisper or a dry hoarseness being produced when attempting to speak. The tumour may be large enough to interfere with the breathing, in which case dyspnoea is the result, and when it occupies the space between the cords it not only causes aphonia, but also dyspnoea, because the space at that spot is narrow. There is of course a marked difference in the dyspnoea when the patient is still, compared with when exerting himself or engaged in active exercise.

Treatment.—If growing, or if affecting the breathing, operative interference becomes necessary. If the tumour be malignant it is unsurgical to attempt its removal by way of the mouth, and it then becomes a question for the patient to decide whether he will have it removed from without, an operation necessitating usually the removal of the larynx. If the tumour be benign it is probably syphilitic wart, or papilloma, or fibro-mucous polyp.

I have come to the conclusion that syphilitic growths are very rare, and are rather simulated by mucous patches upon the cords which yield readily to the treatment of large doses of iodide of potassium. A papilloma may be removed by way of the mouth, but this growth is usually multiple, and may require external incision for its removal. A polyp may, as a rule, be removed through the mouth.

The diagram represents a fibro-mucous polyp, which owing to its position between the cords I was unable

either to grasp or to injure sufficiently to cause its atrophy, and I ultimately removed it from below, after performing the operation of laryngotomy.

DIAGNOSIS OF THE CAUSE OF HOARSENESS AND LOSS OF VOICE.

First Question.—How long has the voice been affected?

I usually gather from this whether an acute or chronic condition, and I hear the sound of the voice. If an affection of the mucous membrane, a breaking voice; fibrous bands dry, deep, gruff or whistling; muscle deep, but regular; nerve, bulbar or bilateral paralysis—inspiratory effort; unilateral paralysis; spasmodic voice with some sounds clear. Hysteria—complete aphonia. Tumours—very variable.

By Laryngoscopic Examination may be detected redness of catarrh, or affection of mucous membrane. Swelling of laryngitis, with, perhaps, ulceration if syphilis, or tubercle. Diminished action of cords, if bilateral or bulbar paralysis. Central position of one cord, if unilateral paralysis. Usually anæmia, if hysteria. Nothing, if muscular. Tumour, if present.

If I conclude that it is *Chronic Catarrh*, I must carefully diagnose that it is not chronic catarrh of phthisis, the objective sign of which is swelling of false cords, because there is always in these cases a true laryngitis in addition. The subjective symptoms of tubercle in other parts must be weighed.

If *Laryngitis*, diagnosis between syphilitic and tubercular must be made, which, as a rule, is an easy matter, because of the history and other signs of syphilis, or of the history and other signs of tubercle. One must, however, be certain that it is laryngitis, and not a severe form of chronic laryngeal catarrh.

If *Bilateral Paralysis*, ascertain that it is not due to destruction of the fixed points of muscles, such as necrosis of cricoid, without difficulty recognised by odour of breath other signs of syphilis or tubercle—then it is proved to be a central paralysis.

If *Unilateral Paralysis*, diagnosis is not difficult between the three forms—Inflammation, Aneurism, Malignant or other Growths.

If *no Change* in larynx, the condition is due to muscular fault, or mental (hysteria)—if *Muscular*, gruff voice; if *Mental*, complete aphonia.

If *Tumour*, the laryngoscope alone can make the diagnosis certain.

Having proved a disease negatively by exclusion of all others, it must be then proved positively by its own particular signs and symptoms.

GANGRENE. (a)

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S.,
Emeritus Professor of Clinical Surgery at the London Hospital;
Consulting Surgeon to the London Hospital, and to the Royal
London Ophthalmic Hospital.

(Continued from page 177).

CASE VII.—An old gentleman, æt. 63, came under treatment for popliteal aneurism, which, after compression, became quite solid. The limb then became much colder, and anæsthesia was apparent in it, on account of the defective circulation taking place through it and consequent deficient blood supply to the nerves. It

was carefully wrapped in cotton-wool, but, spite of all precautions, it continued livid for several days, and ultimately gangrene, not of the whole foot, but only of the great toe, supervened, the disease being of the dry mummified variety. Nothing was done to this for a month, and then, sufficient delay having taken place to admit of any further development of the gangrene if it was to occur, the toe was amputated, though, even then, Mr. Hutchinson said, he performed the operation somewhat unwillingly. Good recovery, however, ensued, and the case afforded a good example of the kind of gangrene induced by occlusion of the main trunk of a limb. It ordinarily occurs in such cases that collateral circulation is established with sufficient rapidity to ensure preservation of the whole member; but sometimes, as in the case just described, the rigid and unyielding state of the degenerated arterial walls may seriously interfere to prevent so desirable a consequence.

CASE VIII.—A young girl, æt. 10, who had been under treatment for rheumatism, and who was the subject of mitral, tricuspid, and aortic valve lesions, was transferred to the surgical side of the hospital because of gangrene which had attacked one extremity; and subsequently the other also was involved. In this patient, plugging of the arteries had taken place by means of vegetations detached from the cardiac valves, and thence hurried into the circulation. In a long period no line of demarcation made its appearance, and at no time could the idea of amputation be entertained, the feeble constitutional state of the patient affording a plain contra-indication to it. Her urine was loaded with albumen, and in other ways she was far too ill to be submitted to interference with a view to removing the gangrenous members. She lived about a month after the disease first showed itself, and there was no evidence of septicæmia.

CASE IX.—A farm labourer was seen, in 1874, by Mr. Hutchinson at Maldon. He had been previously healthy until attacked by rheumatic fever, which left him with cardiac disease, and a liability to embolism. He became suddenly ill; had a rigor; and grew very depressed in spirits. On examination, it was found that the femoral artery on one side was quite pulseless; and the foot below it became rapidly gangrenous. Amputation had been urged by the local surgeon, but a definite line of demarcation having formed when Mr. Hutchinson was called to see the patient, division of the tissues having taken place almost to the bone, he advised against it, being convinced that spontaneous separation might be expected. Two or three months later, the same patient presented himself at the London Hospital because of protrusion of the ends of the bones through the stump after the foot had separated; and these being trimmed, good recovery took place.

This case affords another example of the fact that plugging of the femoral artery may induce gangrene of the parts below it.

CASE X.—About ten or eleven years ago, a man, æt. 30, was admitted into the London Hospital, for gangrene. He had been a soldier in the Crimea, where he suffered from frost-bite of a toe, but recovered. Later, he was engaged on military duty in Canada, also; and there, as well, he was exposed to cold, but was not again frost-bitten. Slowly, however, one foot became gangrenous, and he was invalided home. On admission to the hospital, he came under Mr. Hutchinson's care, and amputation was delayed for the purpose of watching what the progress of events would be in this case. In the absence of the surgeon, however, a colleague took upon himself to remove the foot; the flaps sloughed, and the gangrene extended upwards; and on his return, Mr. Hutchinson decided to amputate the limb at a much higher situation. It was only when this had been done that the femoral artery was found to be occluded, the cause of obliteration being probably an arteritis originating below as a consequence of the frost-

(a) Abstract of a Lecture delivered on Wednesday, Feb. 13th, at the London Hospital.

bite, and spreading thence up the limb. The first amputation was performed at a point fifteen inches removed from the seat of the disease; but notwithstanding, within twenty-four hours sloughing of the flaps had commenced; the pulse rose to 160 beats per minute; and the patient was delirious and vomiting. The second amputation, below the hip-joint, was done within three days from the first, and the result was a very satisfactory recovery.

This case offers a very good example of the injurious influence exerted on the general health by spreading gangrene, the vomiting and fever, induced by septicaemia, being well marked, and ceasing as soon as the exciting cause was removed, the contamination of the blood being accounted for by its circulation through tissues laden with the elements of decomposing and dead structures.

CASE XI.—A man, æt. between 60 and 70, burnt his hand, but not in any way severely, and was admitted into hospital with the member in a state of gangrene, which was gradually extending up the forearm. The patient was very ill; weak pulse, high temperature, furred tongue, &c., and at the same time with these symptoms there was going on progressive plugging of the arteries of the limb, as in Mr. Gould's case; and also, as in that case, involving all the vessels on to the axillary. Amputation at the shoulder-joint was performed, and there was no bleeding during the operation, the main artery being as thick as the forefinger, and solid from presence of clot in it. The arteries, notwithstanding the senility of the patient, were not calcareous; but they were extremely tortuous, and throughout the whole limb they were much dilated and thrombosed from the site of injury upwards.

CASE XII.—A gentleman came under treatment for gangrene of one foot which had followed exposure to cold during snowy weather. He had possessed a feeble and peculiar circulation throughout his whole life; his ears became livid on the least exposure to cold, and his cheeks always presented a flushed appearance, these being symptoms of a debilitated arterial system, which also was affected by calcareous degeneration of the walls of the vessels. He had been accustomed to free indulgence in spirituous liquors; suffered from diabetes with albuminuria; and the pulse beat at the wrist was very feebly developed. The gangrene of the foot progressed so far that sloughing of the toes ensued, and exfoliation of their bones; and the question of amputation had to be considered. The patient was, by virtue of the enfeebled state of his system, an unfavourable subject for operation, and Mr. Hutchinson was somewhat unwilling to submit him to the risks it would necessarily incur; but as the gangrene continued to spread up the limb, amputation was at length resorted to, through the thigh. On dressing the stump subsequently, it was found that the femoral artery formed a dense solid rod, having very much the appearance of a cedar pencil. The patient made a good recovery.

The group of cases narrated thus far illustrates all the conditions under which gangrene of the limbs takes place; and although it is not possible to separate them into exclusive or abruptly marked classes, they may nevertheless be broadly classified under two prominent heads. It must be understood, always, that complications may, and do, arise to modify the course pursued in particular instances of injury, and that very various influences will serve to produce such modifications; but with these reservations the disease under notice may be grouped thus:—

A. Gangrene due to peripheral lesion.

B. Gangrene due to arterial lesion.

The first four cases recorded above will fall under the division A; and this must be made to include also those which are commonly described as "traumatic" gangrene, many of which latter owe their origin to injuries of a most severe character. Under B will be included those examples of gangrene which are caused by occlusion of a main artery at a point above the seat of development of

the disease; e.g., in those unfortunate cases where gangrene results after attempts to cure aneurism by means of ligature of the supply artery; or, as in cases like Mr. Gould's and others, where a tumour of some description presses on a main arterial trunk. Embolism, also, forms another example of the influences which suffice for the production of injuries of this nature.

There are other cases, again, in which there may be no actual occlusion of the artery, but in which arterial disease is of so pronounced a character as to lead to defective circulation through the vessels, and to which it may be owing that collateral circulation sufficient for the maintenance of tissue vitality ceases to be possible. This class of cases includes those which are termed instances of senile gangrene, and which name is not to be regarded as synonymous with "dry gangrene," the occurrence of which is not essentially determined by the factor of age alone. Typical dry or mummifying gangrene, indeed, is only rarely encountered, whereas the moist variety of the disease is common; as also are numerous half-way forms and intermediate varieties of the disease. In elderly people even, the majority of cases are of the moist kind, and only those subjects exhibit the mummifying description in whom the tissues are naturally dry and skiny, and slightly or not at all clothed with fat. Temperature and period of the year likewise influence the character of the resulting gangrene; and calcareous degeneration of the general arterial system is undoubtedly an efficient agent in inducing the senile variety of gangrene.

The disease known as arteritis obliterans is but ill understood; it is a mixed condition in which inflammation of the arterial structures plays a part, and is usually secondary to exposure to cold.

In respect to rules for practice in treatment of gangrene, Mr. Hutchinson insisted on the necessity for amputation in cases where death is threatened from the influence of the gangrene, and whenever the removal of a limb or part of a limb appears desirable, and can be undertaken without risk. Whenever, however, a well-marked line of demarcation is apparent, and reasonable expectation of recovery can be entertained, and no fear of spreading is felt, then amputation is uncalled for and unnecessary. Formerly the evidence of demarcation was taken to indicate that the time for amputation had arrived; and in this respect modern procedure exactly reverses older rules.

Should the main artery above the gangrenous part be occluded, then it is absolutely necessary to amputate high up; and this rule is a very important one to observe. On the other hand, when the whole arterial system is diseased, it is desirable, but not imperative, to amputate high up.

OLD AGE. (a)

By JOHN FOSTER, M.D., F.R.C.S. Eng.,
Bradford.

OLD age has formed the subject of thought and of writing among poets, philosophers, and physicians, in all ages, because it is the goal to which all life tends; and because it is necessarily associated with thoughts of that great problem—life, and that equally great problem—death. It would be impossible for so interesting a subject to have escaped such great observers as Shakespeare and Addison, and we accordingly find allusions to old age scattered through their works.

The late Dr. Farr, in his classical description of the march through life of a million children, has given, among others, the following results. These results are somewhat modified by subsequent calculations, but they answer my purpose for the present:—

Of a million children nearly 150,000 will die in the first year; 53,000 in the second year; 28,000 in the third year; and less than 4,000 in the thirteenth year.

(a) Read at the February meeting of the Sheffield Medico-Chirurgical Society.

At the end of forty-five years one half the million will have died. At the beginning of sixty years, 370,000 will still be living. At the beginning of seventy years, 238,000 will be living. At the beginning of eighty years, 90,000. At the beginning of eighty-five, 38,000. At the beginning of ninety-five, 2,100. At the beginning of one hundred, 223. At one-hundred-and-eight, 1.

From the Census of 1871, Dr. Farr calculated the mean life-time of both sexes in England to be 40·858, or nearly forty-one years.

Mr. H. Humphreys has shown, however, that in the five years 1876 to 1880 the mean age at death was 43·56 years; females, 45·3; being a gain of nearly two years and three-quarters. Thus within twenty years—withstanding the increased density of the population, notwithstanding the unsanitary condition of large towns suddenly grown large, and the increased birth-rate—more than two and a-half years have been added to the life of every inhabitant of England. He also shows that more than 2,000 years have been added to the lives of every 1,000 males by the reduction of the death-rate in 1876-80.

Many of you will remember that Dr. Rabagliati read a paper in this room which led to an interesting discussion, which was afterwards continued in the *Medical Press*, and made some sensation in the country. He stated that while fewer lives were lost in the earlier years fewer lived to old age, and there was no saving of life at the more useful ages. I am not going into this question now. I admit that such a thing is logically possible, because if all died at the same age nobody would die before or live longer than 43½ years; instead of, at any age from a moment to a hundred years.

This view was forcibly put in the *Spectator* in these terms, "What is the kind of life which is increasing, whether it is young life or mature life or aged life which is being enlarged? Are we young longer or mature longer, or old longer?" Do we live longer or are we only a little slower in dying? And here I am bound to admit that some of the gain in early life is lost in middle life. In other words that while the expectation of life at birth is 2½ years more than it was, the expectation of life from 35 to 60 is somewhat less—a mere fraction.

"Notwithstanding the slight increase of mortality among males aged 35 and upwards, a large portion of the additional survivors live on to the higher ages. Of a thousand born the additional number of survivors is 35 at the age of forty-five, 26 at the age of fifty-five, 9 at sixty-five, 3 at seventy-five, and 1 at eighty-five. The increase in the number of survivors to adult and middle ages is much greater among females." By far the larger proportion of the increased duration of human life in England is lived between 20 and 60.

The object of medical science is to prolong human life to its longest term, and it therefore becomes an interesting question to ascertain what is the natural limit of existence. It is an impossible task to do this with accuracy, and fix a limit beyond which human life cannot pass. Dr. Farr says the natural life time of man is a century. The complete cycle of physiological life is a hundred years. That is the length of time the body will live under the most favourable conditions. Another most interesting question is "When does old age commence?"

Dr. Farr has divided life into stages as follows:—Boyhood, age 10 to 15 years; youth, 15 to 25 years; manhood, 25 to 55 years; maturity, 55 to 75 years; ripeness, 75 to 85 years; old age, 85 and upwards. I should take exception to this division, Oliver Wendell Holmes makes old age to commence at 47, which is as much too early as Dr. Farr's is too late. Old age really begins in certain pathological changes which take place at different ages. It is interesting to learn what are the conditions which hasten or hinder these pathological changes.

It is held that all life begins in a homogeneous or form-

less fluid, and from this develops into the varied forms of living beings. There is a life force, inherited from a pre-existing life, which builds up matter into living tissue and holds it together for a time; and the tenacity with which this force holds organised matter together does not depend on size, or strength, or muscular development altogether, but rather probably on an even balance between the several parts, and on something more. There is an axiom in mechanics that the strength of a chain is equal to the weakest link; so the vital strength of the body is equal to the weakest organ. We all do wax old as a garment—the tissues lose their elasticity, become brittle, and in some cases rotten. After the middle arch of life is passed, these changes become commoner, and there is danger if we continue to put the same pressure on a weakened vessel, that it may burst. In the hurry and strife of life men, and especially medical men, too often forget this truth, and pay the penalty. After the age of fifty or fifty-five a good deal more rest and a good deal more sleep are required than in earlier manhood. The physical powers have begun to fail; the mental powers should be at their best. It is probable that some of the greatest literary productions have been the work of men between fifty and seventy. Living public men in every department of literature, science, art, and politics may be cited in proof.

For many years after the degenerative processes of age have weakened the bodily powers the intellectual powers remain comparatively unaffected. A weakened nerve fibre may retain its continuity, and an atheromatous vessel in the brain its entirety, for a great length of time if no great strain is put upon it, but let that strain be applied, and then the "silver chord is loosened, and the golden bowl is broken at the fountain."

In taking the decennial period 65 to 75, and still following the fortunes of the million children born, we find that 309,029 enter this age and 161,124 leave it alive. Diseases of the brain, heart, and lungs are the most common; 31,400 die of old age. The numbers that enter the next decennial—75 to 85—are 161,124, and the number that leave it alive are 38,565. 122,500 die chiefly of lung, brain, heart, and other local diseases. Nearly 59,000 die of atrophy, debility, and old age. Some writer says that he has met few or no cases of death from *old age*, everybody dying of some recognised disease. It is true that the symptoms of disease become obscure in old age, many cases of pneumonia and other inflammations escaping recognition. But it is also true that many deaths attributed to disease are mainly due to old age. "Slight injuries, cold, heat, want, or attacks which in early years would have been shaken off." Of the million with which we started, 2,153 live to the age of 95; 223 to 100. "Finally, at the age of 108, one solitary life dies." We find that life is beset with dangers, which vary at every stage. Diseases may be roughly divided into two great classes—the parasitic and the degenerative. The former are more prevalent in early, and the latter in the later, stages of life. Of cancer, which is one of the diseases of old age, it is uncertain whether it belongs to the parasitic or the degenerative type. As I am not dealing with the former—parasitic diseases—I will only remark that the more there are saved from the poisonous diseases, the more will remain to die of natural decay. As it is the duty of the physician to help man through as many of these stages as possible, and with as little pain as possible, it becomes important to study how to protect him from accidental diseases in the first place, and how to husband his forces in the second place, so that he may be able to travel as far on the way as possible before the inevitable time when his strength shall fail, and he shall fall out of the march and faint by the way.

The first essential of life is food, and, beyond doubt, of the twelve hundred million inhabitants of the world, the majority are underfed, and a large proportion are improperly fed. Poverty is the lot of the majority of

the world, and the mortality among the poor and the hard-worked at all stages of life is amazingly larger than among the middle and higher classes. The human constitution possesses a great amount of elasticity, and will tolerate departure from correct diet for a length of time, but in the end the penalty is rigorously exacted by Nature. Lessened vitality inevitably follows impoverished blood and ill-nourished tissue. Undoubtedly, men are better fed than formerly, and fewer people die of starvation.

But the increased density of the population by the flocking of people to the towns has introduced fresh dangers or rather intensified old dangers. Unless the sanitary improvements of a district, keep pace with the increase of its population, the mortality inevitably increases. Something like 1-7th of the population of Great Britain live in London, a large portion of the rest live in large towns. Dr. Farr says, "What is especially remarkable in London is the high mortality of all ages after 25." The excessive mortality of London men is due to phthisis and pulmonary disease. The same holds good of all large towns. We see that improved health conditions, and increased population are fighting a great battle and on the whole, if not at every part of the field health is winning.

The conditions under which men live have much to do with their chance of reaching old age, but heredity has also something to do with it. This transmission of qualities acquired and inherited lies at the root of all improvement of the race. To leave the body better than we found it, and transmit that improvement in vital force to posterity is the true evolution by which heredity taints may be abolished. In my student days a cruel pathology was taught that certain constitutions were doomed to hereditary diseases, and distinct lines of demarcation were drawn between those so affected and others. Logically that doctrine can only be sustained in a limited sense. Intermarriage must so mix up blood that no constitution could long remain free from taint. Death is the complement of life. All living bodies have their stages of growth, maturity, and decay. So all the parts of the body go through the same stages. The blood cells, the muscular fibres, the epithelial scales live their time, are cast off, and succeeded by others and often better ones. Thus death is not only the end but the beginning of life. "That which thou sowest is not quickened except it die" is a philosophical truth, and lies at the root of all improvement of the race, as well as at the root of all Christian faith.

The last stage of the journey to this inevitable goal, like all the other stages has its peculiar troubles, diseases and dangers. How these troubles may be relieved, these diseases avoided and this stage of life made easier and longer should be the constant and thoughtful study of every practitioner of medicine.

HOSPITAL WITH CIRCULAR WARDS.

(Communicated by Mr. J. BROWN, F.R.C.S.)

FOR some time past an attempt has been made to raise the funds needed to provide a hospital for the town and district of Burnley, Lancashire. The population exceeds 100,000 persons. In addition to the sum of £1,500, as the nucleus of an endowment fund, the committee have succeeded in obtaining subscriptions to the building fund to the extent of £12,600; and a site of two acres in extent has been given, along with a subscription of £1,000, by the executors of the late Colonel Hargreaves. Towards the building fund over £3,000 have been paid in by the working classes within a period of nine months. This has resulted from systematic collections made at the mills and workshops every four weeks. These collections the committee have suspended for the present, owing to the disturbed state of the cotton trade throughout the whole district, but they hope to be able to resume them ere long.

The plans approved of by the committee provide for the erection of a hospital with one-storey pavilion wards

of the circular form, as suggested by Professor Marshall, President of the Royal College of Surgeons. Two of these wards are to be built at present, with an internal diameter of sixty feet for the accommodation of twenty beds each.

The architects, Messrs. W. Waddington and Son, of Burnley and Manchester, have designed a sun room, or day room, on the top of each ward, with a promenade twelve feet wide all round it. Access to the roof is given by a gently sloping spiral staircase surrounding the smoke and extraction flues, and occupying a closed-in space, in the centre of the ward, sixteen feet in diameter. There is then left for the ward itself an annular space twenty-two feet in width. The height of the ward at the eaves is fifteen feet, and at the inner portion sixteen feet. The roof is formed of concrete supported on iron girders. The lineal wall space of the ward is 189 feet, giving an average wall space per bed, excluding doors, of about 8 feet 4 inches. The floor space is 132 square feet, and the cubic space 1,560 cubic feet per bed. Windows are placed between each bed, extending from two feet and a half from the floor to within a foot of the ceiling; and ample provision is made for ventilating both at the floor level and at a height of about seven feet. From the inner part of the ceiling, and also from the floor, ventilating outlets are led to an extraction shaft which encircles the smoke flues.

The walls of all the wards, water-closets, and bath-rooms are to be of glazed bricks or tiles. The floors of the wards are to be of oak, to be beeswaxed and polished. Separated from each ward by a cross-ventilated corridor are the bath-rooms and water-closets.

Connecting the circular wards with the main corridor is a well-ventilated passage, on either side of which is a single-bedded separation ward; and between these wards and the circular ward are the nurses' room and ward scullery.

A subway is provided from the cellar floor of the administrative block to the wards; in this all pipes will be laid; and along it coal, foul linen, cinders, and sweepings will be conveyed.

Provision is made on the site for the addition of four other wards similar in size to those described, and also for a children's ward for fourteen beds, intended to be forty feet in diameter, to have no central staircase, a sun-room, and to have a dome-shaped ceiling.

Clinical Records.

GLASGOW WESTERN INFIRMARY.

A Few Dislocations.

Under the care of ALEXANDER PATTERSON, M.D., F.R.C.S.E., Surgeon to and Lecturer on Clinical Surgery at the Western Infirmary.

Old Dislocation of Shoulder.—M. G., æt. 20, residing near Carlisle, was admitted to Ward 12 on the 5th of August, 1881, with dislocation of left humerus into axilla. Exactly sixty days, or eight and a-half weeks ago, whilst rapidly descending a hill, she fell, pitching with her left shoulder upon a stone. The accident was looked upon as a bruise, and ointments were supplied her for the purpose of friction, no attempt at reduction having been made. The dislocation was with some difficulty reduced by means of the heel in the axilla, by my assistant, Dr. J. W. Downie.

Old Dislocation of Elbow, both bones backwards.—D. L., æt. 37, was admitted to Ward 14 on the 15th October, 1881, with right arm rigid, and nearly straight. While the hand lay nearly prone the upper part of forearm was perfectly supine, and the elbow could not be flexed. The position of the hand in relation to the forearm was what most attracted attention. Monday, 17th Oct., 1881, L. was placed under the influence of chloroform, when it was clearly obvious that there was a marked depression above the olecranon, and that we could, even with the anæsthetic, barely bring the arm to a right angle; on doing so, the middle limb of the triceps muscle became exceedingly tense, as well as a band on the outer and anterior

aspect of the joint, which appeared to be still more engaged in opposing reduction. Simple extension was tried in the first place; then, as the arm lay on the mattress, the foot was placed on the lower end of the humerus, the forearm being flexed and drawn strongly upwards, and this manoeuvre also failed. Next with a tenotomy knife I divided the middle attachment of the triceps, and then the remaining opposing band, when the bones were placed in position with great ease. A rectangular splint was applied, the man ultimately regaining perfect use of the joint.

Old Dislocation of Elbow, both bones backwards.—Mrs. J. B., *et. 33*, was admitted to Ward 12 on the 19th November, 1883. Patient comes in complaining of a stiff elbow-joint, the stiffening being the result of a fall sustained in the middle of last August, *three months ago*. On examination the nature of the accident is easily ascertained to have been displacement backwards of both forearm bones, and there is no evidence of fracture. November 29th, patient having been anaesthetised, and the joint flexed nearly to a right angle, beyond which we could not go with safety, bands of adhesion were heard snapping. The arm was next extended, a skein of worsted fixed around the wrist, and steady extension made by two assistants and myself without success. With the forearm extended, a tenotomy knife was introduced, and on flexing the elbow a tense band lying to the outer side of the triceps tendon was divided, then the triceps tendon itself was cut, when the dislocation was at once reduced.

Dislocation of Great Toe.—G. M., aged 19 years, carpenter. Admitted to Ward 14 on 21st November, 1883, complaining of swelling and pain of the great toe of right foot, this condition being the result of an accident sustained two weeks prior to admission. At that time, while climbing a ladder on board ship, he stumbled and fell, the digital end of his foot coming violently in contact with the deck. Since that time he has observed that the great toe has been swollen and much shorter than it ought to be, and now he can walk only with difficulty. It is worthy of note that he had his boots on at the time of the accident. On examination the proximal end of the first phalanx is found to be resting on the upper surface of the extremity of the first metatarsal, in this way accounting for the shortening of the toe observed by the patient. November 23rd, 1883, patient being under chloroform, reduction was attempted by manipulation; next by extension by means of the "clove hitch;" then by the old-fashioned "door-key" method, all failing. Now with a tenotomy knife all the structures around the joint which appeared tense were divided, and without effect. Finally a linear incision was made antiseptically, on the plantar surface of the foot, corresponding to the head of the first metatarsal bone, the end of which was snipped off with bone forceps, when reduction was effected. The patient was dismissed on January 26th, 1884. I have had very considerable experience in the reduction of dislocations, and never in any case reduced by me have I had so much trouble as in the reduction of this dislocation of the great toe. Fortunately for us, it is a very rare form of accident.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 22ND, 1884.

The President, Sir ANDREW CLARK, Bart., M.D., LL.D., in the chair.

Mr. MANSELL MOULLIN on

THROMBOSIS OF INFERIOR VENA CAVA.

The patient was a man, *et. 35*, who was admitted into the London Hospital in August, 1883, for varicose veins and ulceration of the left lower extremity. He was employed as a paper-hanger; had been a trumpeter in the army, but had never had syphilis. There was no history of gout. A year and nine months before admission he fell down a staircase on to his back, cutting his right leg severely, and falling with his loins across the hand-rail. From the effects of this accident he was confined to bed for five weeks, his right leg (the one that was injured) becoming much swollen, though he is quite positive they never stood out as they do in the left. While in bed, three weeks after his fall, he noticed that the veins in the lower part of the abdomen were enlarged, and from that time they have gone on

gradually increasing in size and spreading in extent up to the present time. There does not appear to have been at any time either general anasarca or hæmaturia, judging from the statements made by himself and his friends. On admission, it was noticed at once that the abdomen was covered with great clusters of tortuous veins, which might be divided into three main groups—two on the left side, the one having its origin in Scarpa's triangle, and the other just above the crest of the ilium; and the third on the right, behind, some four inches to the right of the vertebral column; and from these main groups great coils of enormously distended veins stretched upwards, gradually diminishing in size as they reached the thorax and could pour their contents into the superior epigastric, intercostals, and long thoracic veins. The right epigastric was but slightly enlarged in comparison, but in this as in all the rest the current was upwards in direction. The left limb was so swollen as only to be lifted with difficulty; the right, six inches less in circumference, was almost normal. In the abdomen was a large ill-defined mass lying in front of the vertebral column, most prominent opposite the umbilicus, and running down to the right of this a line along which pulsation and a systolic thrill and bruit could easily be ascertained. Besides this, in the large left lumbar cluster were a continuous thrill and an exceedingly loud bruit. There were no signs of aneurism, the pulsation in the abdomen being distinctly not expansile; the lungs were emphysematous; the heart slightly enlarged and the aorta dilated; there were no hæmorrhoids, or varicocele to any extent, or albuminuria. The diagnosis made was that of thrombosis of the inferior vena cava, with a clot extending down through the left iliacs to the femoral on that side, the ill-defined tumour in the abdomen being the plugged inferior cava, with swollen and oedematous tissue round it, the line of pulsation corresponding to some large abdominal vessel, probably the superior mesenteric displaced to one side. The thrombus could never have extended above the renal veins, but there is no evidence to show whether it originated in a small trunk and spread on till it involved the cava, ceasing where the renal veins poured in a large current, or started in the cava itself. There is, however, little doubt that from the time of its occurrence that it must be directly connected with the accident. Reference was made to a case published by Robin, in which violent exertion while in a stooping position produced the same result; and to other cases, which tended to show that complete obstruction of the inferior cava by tumours or otherwise need not of itself cause appreciable enlargement of the external veins or much oedema.

Mr. MOULLIN explained, in reply to a question by Sir Andrew Clark, that no examination of the urine had been made since the patient was in hospital, three months ago. Should he be able to keep it under observation he would report the progress of the case to the Society.

Mr. R. CLEMENT LUCAS on a case of CHARCOT'S JOINT DISEASE ATTACKING THE RIGHT ELBOW AND FOOT.

The patient was a man, *et. 39*, who came under notice last autumn, and was at that time exhibited at the Society. His father died of heavy drinking and consumption. His mother is still living, but suffering from dropsy and asthma. He is one of nine children, seven of whom are living. One brother was a cripple from right-side paralysis from birth, but lived to be 40. He denies having had syphilis, and there is no history of fits or insanity in the family. He has been much exposed, as a hawker, to wet and cold, and has drunk freely. About four or five years ago he became subject to rheumatic pains which shot through him. He has had neither girdle-pains nor gastric crises. For twelve or eighteen months he has had occasional numbness in his hands, especially the right, and has found a difficulty in buttoning his collar and in walking in the dark. Eight or nine months ago he had an attack of double vision, which lasted about a week, and then passed off. He occasionally felt giddy when starting to work in the morning, but was unconscious of any decline or defect in walking. About two years ago his right elbow became enlarged, but not very painful. He sought advice, and was treated with blue ointment. He has continued to work with it ever since. A few weeks before being seen his right foot became somewhat suddenly enlarged, red and painful, and it was on this account that he came under my care. The swelling extended from the malleoli to the bases of the metatarsal bones, and occupied the dorsum and sides of the tarsus. It was neither oedematous nor tender, but he suffered from aching pain beneath the head

of the astragalus, especially after walking. The right elbow-joint presented a remarkable deformity. On the back of the ulna, two inches from the tip of the olecranon, was a rounded projection about the size of half a Tangerine orange, 2 inches in diameter and bony, at the base. Between the head of the radius and the olecranon was another projection, sharp, prominent, and bony, apparently growing from the radius; and another prominence continuous with this between the head of the radius and the external condyle. These latter projections absolutely prevented all pronation and supination. A small outgrowth sprang from the inner side of olecranon, and projected beneath the internal condyle. In front of the joint, just external to the tendon of the biceps, was a rounded swelling an inch and a-half in diameter, covered by muscles. Flexion of the elbow could be carried to the normal limit, but extension was arrested at an angle of 150° . The joint was free from pain. It measured about $2\frac{1}{2}$ inches more in circumference than the other. The signs of locomotor ataxy were as follows:—He was unsteady when his eyes were closed; if told to touch his nose with his eyes shut he often missed the mark; he had difficulty in walking in the dark and in buttoning his shirt collar. His pupils were not contracted, but unequal, and insensitive to light; patellar reflexes were entirely absent. Mr. Lucas alluded to the liability there was of these cases being mistaken for osteo-arthritis. He thought it rare for the joint affection to be in advance of the ordinary symptoms of ataxy. More generally the paralytic symptoms had existed some time before the joints suffered. Surgeons had been blamed for not recognising the disease. The symptoms he thought were sufficiently distinct, but the disease was not common among surgical out-patients.

The PRESIDENT inquired if any eruption had appeared on the seats of pain, and

Mr. CLEMENT LUCAS replied in the negative.

Dr. BUZZARD considered that this case was in itself an illustration of the reason why they were regarded as of such rare occurrence. Even Mr. Lucas did not fully arrive at a diagnosis in respect of it until he had seen it a second time; and until the onset of ataxic symptoms difficulty would be experienced in this connection. It was unquestionably a fact as Mr. Lucas had asserted, that this disease had been mistaken for chronic rheumatic arthritis, even by examiners in surgery. He himself had exhibited before the society a man who was the subject of Charcot's joint disease in one shoulder, and who, previously to becoming an out-patient at Guy's Hospital, had undergone treatment at two other hospitals in London, with improvement resulting therefrom. It was, of course, possible that the disease was correctly diagnosed in this instance; but if so, it was strange the case was not kept in, as an example for clinical purposes. The man had been finally directed to Guy's by a lady district visitor, who saw that he was affected with an unusual form of joint affection. In this case there was no ataxic gait, but the ataxy of the upper extremities was well marked. The patient was a cabinet maker, and for some time before the joint became swelled up, he had noticed a want of muscular co-ordination which prevented his working at his trade efficiently. There was a development of ocular symptoms in the case, with paresis of the muscles supplied by the right oculo-motor nerve; darting pains had been experienced in the fingers, the ends of which were quite numb. The symptoms were first noticed last October. Dr. Buzzard was of opinion that in this case no destruction of bone had taken place as yet, and that the lesion was confined to the synovial structures; Mr. Lucas' being peculiar from the amount of bony growth it exhibited, and from the absence at any time of much fluid in the joint. Apparently, too, there had not been the usual destruction of ligaments with wearing down of the bones, as ordinarily witnessed. In many cases the ligaments suffered first of all, and great laxity of the joint ensued in consequence. Concerning the medullary origin of the lesion in these cases, further observation only confirmed the views he had already expressed. Quite 50 per cent. of cases were characterised by the occurrence of gastric or laryngeal crisis, or of frequent calls to stool. Experience had shown that all parts of the spinal cord might become diseased, and still the particular affection under discussion not be produced, and a process of exclusion led to the inference that the medulla must be the seat of injury. The centre affected might, moreover, be directly associated with nutrition of the osseous system, or it might be the vaso-motor system that was implicated. There was difficulty, however, in explaining why only the bone should be affected and not the contiguous muscles.

Dr. HALE WHITE referred to a distorted pelvis discovered in the dissecting-room at Guy's Hospital, and which was the first example of Charcot's joint disease seen post-mortem. Dr. White then proceeded to explain the current views of the affection, and gave his own reasons for holding it to be of nervous origin.

Dr. ALTHAUS thought it was important to possess more ample pathological details before definitely accepting any view of causation. He was unable to adopt Dr. Buzzard's views, but rather inclined to accept a local causation in the presence of old neuritis and trophic disturbance. Anesthesia and analgesia were often found to be present in tabetic subjects, while in others nothing of the kind was observed.

Dr. BUZZARD explained that in contrast to the opinions quoted from the French by Dr. Althaus, Charcot himself had described in his lectures a recent case in which the anterior horns of the spinal cord were found in a healthy state, and also the peripheral nerves as well.

Dr. MOXON said that, though he had seen many cases of tabes, he had not yet encountered one of Charcot's joint disease; and he found it difficult to accept Dr. Buzzard's theory because of the singular partiality the disease evinced for single joints. It might have been expected that, if it had a central origin, its distribution would be of a less particular character. He had made notes of thirty-three cases of ataxy, in none of which had the joint affection been observed. Could Dr. Buzzard say in what proportion Charcot's disease did occur? and also the number in whom chronic arthritis developed? In his own practice he (Dr. Moxon) had been struck by the frequency of "gastric cases" among his patients.

The PRESIDENT expressed his belief that Charcot's joint disease attended other nervous diseases as well as locomotor ataxy.

Mr. CLEMENT LUCAS observed that the case he had recorded was, as Dr. Buzzard implied, an exceptional one from the presence of the exostoses attending it, and it was on this account that he had invited discussion upon it. It was altogether removed from any joint affection he had previously experienced. Absence of pain from the elbow-joint, also, made it quite unlike a case of osteoid arthritis. He was glad to learn from Dr. Hale White that Charcot had recognised the pelvis described by the latter as affording evidence of the existence of the disease during life.

Mr. NOBLE SMITH on a case of

DISLOCATION OF ONE OF THE SEMI-LUNAR FIBRO-CARTILAGES OF THE KNEE-JOINT.

The left knee was first injured sixteen years ago (1867) by a fall. Great pain was felt, and while being carried home the patient was upset, the knee again twisted, and the intense pain was immediately relieved. This history was considered as characteristic of displacement of one of the cartilages. The patient was unable to move for many months, rest and local applications being prescribed. After nine months walking was commenced again. The subsequent history was that of repeated injury from trivial causes and a continued state of weakness of the joint, with discomfort or pain during movement. The same kind of treatment was always prescribed, and in the course of weeks or months after each accident the patient would gradually recover sufficiently to be able to get about again, but always with difficulty and in danger. On November 11th, 1882, this patient was first seen by Mr. Noble Smith. A stiff knee-cap was being worn, and any locomotion was extremely difficult. Rest as complete as possible had lately been again recommended, and the advice was being carefully followed. The knee was slightly flexed, and could not be moved without pain being produced. The internal cartilage of the left knee was felt to project slightly beyond the upper border of the tibia. Upon pressure being applied to this protrusion while the leg was flexed and extended repeatedly, the cartilage was felt to slip back, after which the patient walked round the room perfectly naturally, and felt a relief which had only once been experienced since the first occurrence of the accident. A pad was strapped over the place where the cartilage had protruded. During the next few weeks there was a tendency to relapse, but by perseverance with the treatment the joint was gradually worked into a natural condition. An apparatus was made, which, while it permitted flexion and extension of the leg, prevented lateral motion and twisting. Walking exercise was recommended from the first, provided no pain was felt. This

patient has remained quite well up to the present time, December, 1883. Several other similar cases had been met with by Mr. Smith. Great care in forming a diagnosis is necessary. This displacement, which was first described and the appropriate treatment devised by Mr. Hey, of Leeds, is to be distinguished from inflammatory disorders and the presence of loose cartilages. The variety of the conditions which may occur are described by Hamilton. Bonnet, of Lyons, experimented upon a dead body, and produced displacement of the inner cartilage, and subsequently reduced the dislocation by extension. The experiment was frequently repeated with a similar result.

Mr. HOWARD MARSH corrected the impression conveyed by Mr. Smith to the effect that he (Mr. Marsh) was the inventor of the instrument referred to. He believed the internal cartilage was more often displaced than the external, but it was important to remember that the latter was also often subjected to such accident, as instanced by Ferguson, Godlee, and others. The injury was produced as a result of relaxation of the ligaments of the joint, and by tearing away of attachments, as might result from accident during football playing. He would insist on the necessity of mechanical treatment of these cases; and at St. Bartholomew's Hospital at least thirty had been treated by means of the clamp he exhibited, and with much success. This consisted of an improved instrument, suggested by Sir James Paget, in which a semi-lunar piece of metal was provided with two horns, and with these the patella was firmly held in situ.

Dr. TYSON narrated a case recently under his care. It was that of a woman, æt. 59, who had for ten years been suffering from displacement of the internal cartilage, the reposition of which was effected with much difficulty, and only after flexion and external rotation of the limb, with subsequent application of a knee-cap. He was glad to see the improved form of instrument exhibited to the Society, and proposed to make trial of it.

Mr. CLEMENT LUCAS remarked that all his own cases were examples of displacement of the external cartilage.

Mr. NOBLE SMITH said that all his own cases were those of displacement of the internal cartilage. The history of each pointed to the causation by sudden, forced, and unarrested movement of the limb. Thorough reduction of the displacement was essential before application of any kind of apparatus. Rest alone could not be relied on as a mode of treatment.

The PRESIDENT announced the appointment of a Committee, consisting of Drs. Fred. Taylor, Douglas Powell, Moxon, and J. K. Fowler, to consider and report upon a case of pulmonary regurgitation exhibited to the Society by Dr. Fowler.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE TRAINING OF ASYLUM ATTENDANTS.

THE Scottish quarterly meeting of this Association was held at Glasgow on Feb. 21. The committee appointed to deliberate on the best means of improving the training of asylum attendants met in the forenoon and devoted its attention chiefly to framing the outlines of a "Manual of Instructions" to be recommended for adoption in asylums. The question of lectures and individual training was left for future consideration, when a more extensive experience will probably justify the issuing of a recommendation by the committee.

THOUGHT-READING.

The quarterly meeting proper met in the afternoon, and as there were no papers to read, various subjects for discussion were suggested, selection being given to thought-reading, which was introduced by Dr. Clouston, the chairman, who took an elaborate survey of the recent doings in Edinburgh of Mr. Stewart Cumberland and other so-called thought-readers. The thread of discussion was afterwards taken up by Dr. Yellowlees, who spoke from a somewhat similar experience in Glasgow, and concurred in Dr. Clouston's view that it was simply a question of muscle-reading. Dr. Ireland and others followed, giving additional breadth and interest to the discussion. Thereafter followed an unconventional conversation on interesting and isolated clinical cases which had specially been under the notice of the gentlemen present. Members afterwards dined in the Bath Hotel.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

FEBRUARY MEETING.

W. H. ELLIS, M.R.C.S., President, in the chair.

AFTER some preliminary business, Mr. SPENCE (House-Surgeon at the Infirmary), in the absence of Mr. Appleyard, exhibited a specimen of

CALCIFIED TUMOUR OF THE UTERUS.

The tumour was about six inches in diameter, and proved to be a fibroid undergoing degenerative changes. Microscopic examination showed it to consist of involuntary muscular fibre in the centre, this tissue undergoing fatty change towards the periphery, the outer layer being calcareous, and not bony, as was at first supposed; the calcareous layer consisted of carbonate of lime, as proved by its effervescence in dilute hydrochloric acid. The specimen was unfortunately not accompanied by a history of the patient from whom it was taken, except that when separated from the uterus, the mucous lining of the latter was distinctly traceable. The probability was that the patient had ceased to menstruate, and that the tumour was undergoing the last stages of degeneration.

Mr. SPENCE also exhibited specimen of a liver which had been ruptured in two places, the right lobe being extensively implicated. Twenty-six days before the death of the patient he had been knocked down in the street by a cart, the shaft of which struck him in the right hypochondrium. On admission into the Bradford Infirmary he was suffering from exhaustion and abdominal pain; the abdomen on examination was found to be distended, both flanks being dull upon percussion, and the mesial line tympanitic. Mr. Appleyard, under whose care the patient was, aspirated the abdomen without obtaining any fluid. On the death of the patient, a post-mortem examination discovered several pints of thick, dark fluid in the abdomen, and the presence of lymph with intestinal adhesions. Although there had been jaundice, the gall ducts and bladder appeared to be uninjured. The remarkable point in the case was that the ruptures had completely healed, and, but for the peritonitis consequent upon the escape of blood and irritating matter into the abdominal cavity, the patient might have made a perfect recovery.

Mr. SPENCE also exhibited photographs of two cases of osteotomy, showing patients both before and after operation. The cases had been operated upon by Dr. Rabagliati, and the recoveries were perfect. One was a case of curved tibia, and the other of genu valgum, in the latter of which Dr. Rabagliati had divided the femur one and a-half inches above the knee.

Dr. GOYDER remarked that, if these cases of deformity were placed under sufficiently early and proper treatment, subsequent operation would not be necessary; he thought all cases of young children might be treated by proper appliances.

Mr. SPENCE explained that, with respect to the case of genu valgum, pressure had been tried in the form of splints, &c., for three months, but without result. In the other case, the patient was aged 15, and therefore no other treatment but operation was applicable.

Mr. MIALI agreed with Dr. Goyder that these cases taken early could be treated without operation. The splints or apparatus should be applied much longer than three months if necessary. At a Leeds meeting of the Yorkshire Branch of the British Medical Association, several cases of this kind were exhibited, and he had expressed his opinion to the surgeons that all might have been cured without operation by simpler means.

Mr. MARSHALL related a case in point which he had treated successfully with simple cardboard splints and bandages, for which he had substituted, when the child was older, well-adapted boots with high tops. The child could now walk quite easily and had perfectly recovered. Appropriate remedies, such as the syrup of phosphate of lime, should be also given.

Dr. FOSTER then read a major communication upon

OLD AGE,

which will be found at page 202.

In complimenting Dr. Foster upon his paper, the PRESIDENT remarked that, since the introduction of preventive medicine,

thirty years ago, medical men had succeeded in prolonging life considerably. He also stated the fact that Bradford could now claim an exceedingly high position in the diminution of its death-rate.

Dr. HIME (Medical Officer of Health for Bradford) said that, considering the proportion of human life now existing, the present was one of the healthiest periods in history. He gave some interesting particulars as to the relative rates of population in the decennial period from 1871-81, and said that there had been no increase in the life of the population in the ages from 15 to 50, and especially there had been no increase in the life of the working population. He regarded children under 5 years of age as useless, and merely consumers. He thought that Bradford, although at present so healthy, might not always stand so high; phthisis was exceedingly common in it, and it was to be regretted that as much heed was not paid to the causes operating in its production, with a view to their prevention, as was expended upon the detection and prevention of zymotic disease.

Dr. GOYDER remarked that, notwithstanding Dr. Foster had admitted the influence of worry in shortening middle life, he had succeeded in showing, in opposition to Dr. Rabagliati's view, that there was a general gain in the life of the whole population. He could not agree with Dr. Hime's remark of the uselessness of children under five, for although largely doomed to death, through neglect or unavoidable circumstances, they exercised an influence for good upon the minds of parents from their very helplessness, and tended to diminish mortality by increasing the experience of those parents in the rearing of succeeding children.

Dr. HIME disclaimed any imputation on the influence of children for good; that influence was of the most civilising and humanising kind; he had spoken from an economic point of view.

After brief remarks by Dr. TIBBIS and Dr. MCGREGOR, Dr. FOSTER, in reply, said that naturally the discussion had run into a groove similar to his own thoughts when writing the paper, viz., that of infancy. The consideration of the subject necessitated regard being had to both ends of life, for the conditions influencing childhood had a material influence upon the prolongation of its after-life. He held an opposite view to that of Dr. Tibbitts as to greater mortality in the higher classes; poor people in rural districts might live to great age, but in crowded populations, even as healthy as Bradford, the chances of long life were much against the poorer classes.

Department of Lunacy.

LITERATURE.

CLOUSTON ON MENTAL DISEASES. (a)

WHEN Dr. Clouston essayed the task of writing a book on mental diseases, he did well to limit his range of operation to clinical studies. Books of psychological medicine, which take a wider scope, are too frequently disappointing, for the obvious reason that this division of the medical labour field is still full of chaotic difficulty and knotty problems, the solution of which, is supposed to be effected by piling up over them faulty definitions, elaborate and exquisitely refined classifications, and tomes of metaphysical disquisition. These certainly have an historical value, and many of them are excellent in their way; but they are frequently dry, wordy, involved and obscure, and the brain of the average medical man soon tires over them. For him the truly scientific and the truly practical are the clinical, anatomical, physiological, and pathological, and he will rather content himself with a psychological web of his own weaving, till the schools can furnish him with easier stepping stones. By elaborating a strictly clinical work, Dr. Clouston therefore appeals to a wide circle of medical readers, and he is enabled to treat this branch of the subject with a freedom and fulness which would otherwise have been impossible.

Starting in his opening lecture with the proposition that all men are students of mind, the author proceeds to indicate the rare opportunities possessed by the physician for the construction of a practical psychology of his own, and

thereafter points out the necessity for medical men studying mental disease, concluding with a series of valuable directions for examining an insane patient. The remaining eighteen lectures furnish graphic pictures of mental disease, culled from a consideration of two hundred and sixty cases, and incidentally, reference is made by the way, to pathological features of proximate utility, or rare histological interest. Dr. Clouston's pictures of mental disease are vivid, realistic, and true to nature; his style is terse and yet vigorous; and paradoxical as it may seem to say so, one charm of his book is the dogmatism of his therapeutics. The Scotch stomach must be extremely capacious, and the rapidity of the Scotch digestion must surely be prodigious. The apparently indiscriminate and wholesale use of milk and eggs at Morningside, is more likely to arrest, than to further digestion, and we would recommend to Dr. Clouston, pending the probable necessity of a second edition of his book, an experimental study of the relative merits of one or two egg custards as compared with four egg custards. The digestive troubles of the insane have not yet been so thoroughly investigated as they deserve to be, and undoubtedly there frequently exist in them various anomalies of the mucus and digestive secretions, which are inimical to heavy, or voluminous dieting. There is something enviable in Dr. Clouston's optimism: it is refreshing and stimulating to find him after twenty years' experience, still strong of faith in the efficacy of therapeutics. The medical psychologist too frequently begins by constructing a system of therapeutics with great enthusiasm, and ends with blind unbelief.

We also envy Dr. Clouston his literary faculty, he is nothing if not original in his use of words and phrases, but his usually clear and pithy treatment of the subject is sometimes marred by the intervention of obscure passages and indefinable definitions. One of his favourite expressions is *mental pain*, a word the precise application and utility of which, we are at a loss to comprehend; and he takes us still further beyond our depth, when he states (p. 47) "in some cases the mental pain is, as it were negative, rather than positive," and adds no word of explanation. Except occasional signs of hurry in the get up of the book, typographical errors which are rather too frequent, and deficiencies of the index, there are few openings for criticism, and there is no room for any serious objection. The author is to be congratulated on the success which has attended its publication, on the thoroughness with which he has entered into clinical details, and on the exceedingly compact, practical, and readable book, which he has sent out to the medical profession. That the latter will appreciate the book there can be no doubt whatever; it will find an appropriate place in the library of any medical man or medical student; and it will materially advance Dr. Clouston's reputation as an authority on the clinical features and therapeutics of mental disease.

MANN ON PSYCHOLOGICAL MEDICINE. (a)

A BOOK that will keep its head above water in the medical world requires no less than in the outer world to possess a *raison d'être* better than can be discovered in many that have recently issued from the press. The surfeit of medical books which are at present seeking for local habitations and a worldwide name is simply legion; and still the reckless issue continues. In Medicine, Surgery, and their specialisms, the litter of books is assuming grave proportions, and the progenitors of these are responsible for much confusion as to what is really necessary and what is virtually useless. The fact is painfully evident that our books are multiplying out of all keeping with the actual development of the science, and it is deplorable that so many go to the wall only after they have damaged the circulation of better competitors. These remarks are especially suggested by the frequent appearance of late of works on psychological medicine.

The book presently under review hails from the other side of the Atlantic, and professes to fence in not only the ground of Insanity proper, but of allied nervous diseases in as concise a form as possible. A very cursory study will suffice to show that it does neither the one nor the other, and so far as descriptions of mental disease go, we might recommend Quain's Dictionary or Aitken's Practice of Medicine much more appro-

(a) "Clinical Lectures on Mental Diseases." London: J. & A. Churchill.

(a) "Mann's Manual of Psychological Medicine and Allied Nervous Diseases." London: J. and A. Churchill.

priately. Dipsomania is treated of under Nervous Diseases; General Paralysis under Mental Diseases. The chapter on Treatment of Insanity occupies 110 pages, consisting of wholesale quotations from Asylum reports and from the evidence submitted to the Parliamentary Committee of 1877; fourteen statistical tables; several pages of emphatic belief in the efficacy of certain drugs and certain combinations; and thirteen pages on the varieties of insanity in relation to treatment. This last embraces all that we are permitted to learn regarding epileptic, masturbatic, hysterical, gestational, puerperal, isothermal, climatic, abdominal, post-febrile, phthisical, syphilitic and alcoholic insanities. Chap. xv. is intended to teach what is worth knowing of lunacy in England and Scotland, and is simply made up of quotations from Orders of the English Board of Lunacy, and from the writings of the late Dr. Forbes Winslow, and a directory of a few asylums and their superintendents singled out for special mention; and all this without any manifest reason except to swell the bulk of the book.

The arrangement of the book is bad. The facts and theories drawn from sources beyond the author himself are so numerous, that what he can lay claim to as original and worth recording, would not warrant his appearance in the literary world as the writer of a text-book on insanity. We have compilations enough in all conscience, without requiring to multiply and diversify them, and we have no hesitation in drawing the line at a book like this.

Dr. Mann considers that psychological medicine occupies the position of a well-defined and authoritative science. How much we regret that we cannot agree with him! His work deserves a word of commendation in respect of its size, the wealth of information which incoherently and irrelevantly occupies its pages, and the generous manner in which he has acknowledged the labours of others in the close-lying fields of psychiatry and neurology. The fault of the book is clearly due to the fact that Dr. Mann has catered for too wide a circle of readers.

BRAIN.

The last quarterly part of *Brain* leads off with an interesting and suggestive article by Grasset, of Montpellier, on "The Relations of Hysteria with the Scrofulous and Tubercular Diathesis." This paper is one of considerable importance from the point of view of the general practitioner. With a series of eight *personal* and seventeen *borrowed* illustrations, the author demonstrates examples of hysteria combined with scrofulous or tubercular heredity; and in a subsequent issue he proposes to illustrate by a second series of cases, the appearance simultaneously of hysteria and pulmonary disease. Buzzard follows with an excellent clinical and pathological description of a case of *Tubes Dorsalis*, in which he is aided by Bevan Lewis, and from which he concludes that lesions of the cord, in this instance, depend for their origin on peri-arteritis, apparently starting from the soft membranes. The bulky literature of epilepsy is further added to by Beevor's contribution on "The Relation of the Aura Giddiness to Epileptic Seizures." He writes in order to show that "there is some relation between the apparent movement of the patient and objects surrounding him, and the initial rotation of his head at the commencement of the fit." The number is further made up by papers on "A Case of Anæsthesia," by Donkin, a critical digest of a lecture by Byrom Bramwell, on the "Innervation of the Heart," and several reviews and abstracts.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

AMERICAN PORK.—Nearly the whole time of the last meeting of the Académie de Médecine was taken up with a discussion on the introduction of salt pork from America. M. Proust, the reporter of a Commission appointed to study the question, brought before his colleagues the results of their deliberations, and the conclusions were resumed as follows:—1. An epidemic of trichinosis cannot be confounded with an epidemic of typhoid fever, the symptoms, march, duration, pathological anatomy, and nature of the diseases being entirely different. 2. No authentic case

of trichinosis not having been yet reported in France, England, or Belgium, the importation of salted meat from America might be authorized in France. 3. It would be well that instructions as to the proper cooking of pork were widely published and distributed amongst pork butchers, who should be enjoined to make it known to the public. Lastly, that it would be necessary that the history of trichinosis were completed, and that the cause of the immunity enjoyed in this country relative to the parasite should be inquired into. M. Lunier brought forward some statistics relative to the consumption of meat in France, which appears to be 80 lbs. a head a year. In the towns it is as large as 136 lbs., while in the country the consumption does not exceed 48 lbs. The whole taken together represents 28 millions of pounds, of which only 9 per cent. is imported meat. Of the 80 lbs. annually consumed by each inhabitant, pork was entered as one-third of the whole, or 33 per cent.

ESTLANDER'S OPERATION.—M. Féréol brought under the notice of his colleagues the case of a patient completely healed of a pleural fistula by Estlander's operation. The subject was a young man of 22, who eighteen months ago was admitted into the Lariboisière Hospital for pleurisy with extensive effusion. Thoracentesis gave him temporary relief, but the pleural sac refilled after some time, pushing the heart greatly to the right, but this time the patient refused all operative interference. However, the dyspnoea became so distressing that he yielded to the advice of M. Féréol, and nearly two quarts of laudable pus were drawn off by the aspirator. The amelioration which followed was but of short duration, and the operation for empyema was tried, but with no better result. As a last resource resection of the ribs was decided upon, and the consequences were highly satisfactory. From the fourth up to and including the eighth rib were portions removed, and now—six weeks after—the fistula has entirely closed, but the affected side is diminished in circumference by three inches.

EXTIRPATION OF TUBERCULOUS GANGLIONS IN THE NECK.—At the Société de Chirurgie M. Chauvel spoke in a communication of one of his colleagues on extirpation of tuberculous ganglions in the neck performed by him, and which terminated fatally from secondary hæmorrhage. M. Chauvel gave it as his opinion, in view of the facts of the case, that at best it was a dangerous operation, and should not be resorted to until every kind of general treatment had failed. M. Desprès was of the same opinion, and cited a case of purulent infection as the result of the operation. M. Verneuil remarked that in thirty years of practice he extirpated five or six times glands of the nature in question, but he thought that general treatment should be always preferred. M. Trelat, although associating himself with the general opinion of his colleagues, thought that surgical interference should not be wholly condemned. He had found good results from ablation or scraping (*grattage*) effectually the surface laid bare in order to provoke inflammation and adhesion.

Special Article.

KEFIR.

As relevant to, and bearing upon, the subject of our leader on "Koumiss," in the *Medical Press* for February 20th, an esteemed correspondent sends us the following:—

This beverage made from fermented cow's milk has been used in various parts of Russia almost from time immemorial, and is known under a variety of names—"Kefir," "Kapir," "Kyfir," and "Kyppe." As is now pretty generally known

kefir is the name of a peculiar ferment, as well as of the drink produced by it. The ferment is a yellow, granular mass, that swells up slightly in water and gives it a yellow colour. In milk it separates into fine granules, which first swell up and fall to the bottom of the vessel, in about two hours time to rise to the surface again along with bubbles of carbonic acid gas. The liquor when fermented is said to have an agreeable taste. It is now being prepared in many towns in Russia, especially in Moscow, Kijon Jasta, &c. The largest kefir institution is in Piatigorsh in the Caucasus. It is said by some to have certain advantages over koumiss, as containing more albumen, being more agreeable in flavour, very digestible, being useful as a diuretic, diaphoretic and expectorant, and as being prepared from cow's milk, which is of course, in Western countries more easily procurable than mare's milk. At first a glass is given daily, then two glasses, and finally three.

Some observers, on the other hand, are of opinion that it is less valuable than koumiss, and amongst the number the proprietor of a large koumiss establishment in Warsaw, who appears to think that if cow milk koumiss fails it is owing to defective preparation; that the casein of kefir is mostly clotted and sticks to the sides of the glass, that it easily goes bad, especially in the first few days after manufacture, whilst the koumiss prepared by himself remains good for months. Another authority thinks that both kefir and koumiss are in general overrated, and that the good results that sometimes follow the kefir or koumiss cure in an institution are rather owing to fresh and changed surroundings than to anything else, although the strengthening properties of both as of milk preparations generally, cannot be denied.

The following is a comparative analysis of milk, kefir, and koumiss, as drawn up by Tuschinsky, a Russian apothecary:—

Per Thousand	Cows Milk sp. gr. 1028	2nd day. Kefir made from skimmed milk, sp. gr. 1028.	2nd day. Mare's Koumiss (Hartge)
Albuminates ...	48·	38·	11·2
Fats ...	38·	20·	20·5
Lactose ...	41·	20·025·	22·
Lactic acid ...	—	9·	11·5
Alcohol ...	—	8·	16·5
Water ...	873·	904·975·	918·3

Another Russian who has been making observations on cow koumiss is Dr. Ponomaroff, of Charkow, who has been employing it in diseases of children. The conclusions arrived at were that the frequent failures met with in its manufacture, and the want of constancy in its composition are great objections to its employment, that it is not suitable for exclusive use in the case of children, that children under a month old bear it badly, that individuality and age play an important part in regard to its usefulness, but that it is serviceable as an excitant, and that it exerts a good influence on the uropoietic organs in many cases of dyspepsia.

On Friday next the first of the Gulstonian Lectures for the present year will be delivered at the Royal College of Physicians of London by Dr. Clifford Allbutt, the subject being "Visceral Neuroses." Members of the profession are admitted on presentation of visiting card.

A LETTER has arrived from the Queen, appointing Dr. Whiterow, of Magee College, Derry, to the vacant seat on the Senate of the Royal University of Ireland.

WEDNESDAY, MARCH 5, 1884.

CONSIDERING THE POOR.

SOCIAL politicians have long busied themselves over the problem of regeneration as it affects the conditions under which the poorer classes of society eke out a weary existence; and one of the consequences of advancing civilization is that the questions so arising shall have an intimate connection with these details of hygienic well-being that necessarily engage the attention of medical men. Influences of the most important kind in their reaction on health and the comforts that secure immunity from disease, are directly outcoming from surroundings under which life is preserved; and it is a paramount duty with the profession, not only to admit to a sympathy with poverty, but to make also honourable exertion towards ameliorating its ill effects. We do not need to urge that such effects do follow in the wake of destitution, nor to urge their gravity and number; unfortunately, there is too abundant evidence, pointing all in this direction, for scepticism to be possible to the least willing minds; but at length there are to be witnessed the pleasant signs of a determined intention to grapple with the danger, and as far as may be found compatible with reason and justice, to diminish its proportions.

At the outset of that agitation which has recently culminated in the appointment of a Royal Commission of Inquiry into the condition of the poor, probably only the vaguest notions as to remedial measures were entertained; and a first effort was advisedly made to stimulate public interest in a question that is of the first public importance,

though never before elevated to the position it now occupies in public estimation. From this point onwards the labour of exposure has fallen mainly to enthusiasts to perform ; henceforth the statesman and the man of science will be principally occupied with the task of ascertaining what is to be dealt with, and how.

In its narrowest sense the question with which the Commission will be called upon to deal, is that of "housing" the poor ; but in reality it embraces a very much wider area than is implied by the mere nominal description that has been given to it. There is undoubtedly a direct causal relation between squalid dwellings and degenerate physique ; a certain connection between ill-ventilation, absence of sanitary cleanliness, and deficient protection from exposure, and the innumerable bodily ailments that originate from them. There is also a deeper and more fundamental danger to be provided against, and that is the condition of the people themselves, which has resulted from a long continuance of the disabilities under which they labour. If improvement in tenement construction were alone wanting to ensure a return of order and healthfulness among the uncared for and improvident, then we might hopefully look for an immediate change for the better as a result of timely and benevolent interference ; but the truth will have to be faced, that this is but a part, and the smallest part, of the Herculean task confronting us in the future. One of the earliest convictions the Commission will experience is that the very poor are destitute of something more than material means ; that they are sunk into a state of physical and moral despondency, for the production of which continued inheritance of weakly mental and bodily organisations must be held to blame. Generation after generation have been born into the heritage of misery that is the only birthright of large masses of our population ; and each new victim, if it escape the trials of infancy, grows only to the perception of its own increasing helplessness. Not the voluminous records of visits to so-called "alms;" not the oft-repeated "bitter cries;" not the fierce declamation of too-frequently-encountered platform orators, can convey a sense of the reality to which we here refer. Nothing less than actual seeing for oneself will yield a notion of the truth ; and none so much as they who have week after week, and month after month, been engaged in constant intercourse with the people, can properly appreciate their dire need of help to rescue them from the perpetual miseries of their state. Even the eye of the physician fails at first to perceive the full meaning of what it sees in traversing courts and alleys, and in visiting the houses that are situate in them : only when he has been gradually trained to understand the direful signs around him does he entirely comprehend the complete meaning they imply. But once the lesson has been learned he is compelled to the admission that, though there is much to be hoped for from adoption of immediate hygienic measures, still it would be useless to anticipate that anything short of well-sustained and assisted efforts at self-improvement among the people will tend to such results as their earnest well-wishers desire on their behalf ; and then only in another generation than that which will reap the first fruits of benefit.

We would not, however, be understood to deprecate any fashion the movement that is on foot to improve

the dwellings of the poor. Unmistakably the want of efficient accommodation in this respect has been a huge, prominent factor in bringing about such evils as now exist. And, probably, taken with insufficient means of providing for bodily sustenance, and the terrible indulgence in drink, stimulated as this is always by the discomfort of an unhealthy home, it has, in the past, occupied no less important a deteriorating influence than it exerts at present. Moreover, it is the very young who suffer most from such immediate evils. At a period when they most readily react to every injurious influence, their physical development is seriously retarded by reason of the unhealthy surroundings amid which they live ; and consequently they grow to maturity under circumstances that are at once depressing, and prohibitive of normal functional activity, and of healthy development.

There is urgent need just now to remember that it is for beings of this description, and their descendants, that we are about to plan measures of improvement ; that we are called upon to promote the welfare not of normal and average persons, but of such as are debilitated by long inheritance of weaknesses ; and our remedies, bold and sweeping though they be, must be devised with a full understanding of the whole problem involved if they are to be provocative of the benefits they are destined to confer.

The means to be adopted cannot in a moment be suggested. The Commission that is entrusted with the task of recommending them may well be left to utilise the resources open to them ; but whatever the result of its deliberations may be it is right to presume that it will take advantage of every opportunity it possesses for gaining exact and extensive information. We do not, of course, as yet know what means will be appealed to, but we would point out that one at any rate should not be overlooked, viz., the great hospital maternity charities in large towns. The medical officers in charge of these departments have occasions for estimating the amount and incidence of evil surroundings on the condition of the poor such as few others can obtain ; and the information in their possession, if intelligibly conveyed, would be of material assistance in promoting the completeness of the inquiry.

MEDICAL EXAMINATION OF RECRUITS.

THE existing arrangements for examining militia recruits has of late given rise to much dissatisfaction on the part of militia medical officers and civil practitioners in charge of troops, and has, we believe, reacted seriously upon the military service of our country, by causing numbers of eligible recruits to be refused admission to the army. The present system is fixed by warrant. It declares that when recruits are examined at any place outside a brigade depot, the examination shall be made by the militia surgeon or by the civil practitioner in charge. Definite printed rules which declare what shall be a disqualification and explicit instructions how to ascertain the existence of such, are supplied, and it would seem very unlikely that the examining surgeon could make a mistake, and accept a recruit who did not comply with the requirements. But, after the man has been passed at this examination, he has to go forward to the

depôt, where he is again examined by the army medical officer in charge, and the complaint is that recruits are frequently there rejected, whom the original examination declared to be sound and suitable. In considering the justice of this complaint, it is to be remembered that the militia or civil surgeon who made the original examination, is usually a practitioner of old standing and ample experience in the diagnosis of diseased conditions, while the army surgeon who revises his decision, is not uncommonly a young gentleman fresh from Netley, and with little or no experience of such investigation, and it, therefore, seems reasonable when disputes arise, to place confidence in the verdict of the senior practitioner. But we do not complain that, in doubtful cases, the military authorities prefer to rest on the decision of their own regular officer. What we do protest about, is, that the recruit is frequently rejected on the ground that he does not comply with the printed rules, as to height, girth of chest, and acuteness of vision, when, in fact, anyone with the aid of a measuring tape can satisfy himself that he is well within the rejection limit of height, weight, and chest capacity. It seems to be a common occurrence for the army medical officer to refuse recruits for some unknown reason, or, without taking the trouble to measure them, and it is obvious that something must be wrong somewhere, when the printed regulations declare a test of sufficiency, and the army officers do not abide by that test.

Our complaint is, however, that these subsequent rejections of recruits, passed by civil practitioners, inflicts great hardships on those practitioners in respect of their fees. They are called upon to go through this elaborate examination, for which they are to receive four shillings in case the recruit is passed, or two shillings and sixpence if he be found unsuitable. Having done this work and satisfied themselves that the applicant is up to regulation standard, the examiner might reasonably expect to be paid, but, when the recruit goes to the dépôt he finds himself mulcted of his emolument by the rejection of the applicant, it being the rule that, for a recruit rejected by the dépôt surgeon, the civil practitioner receives not a penny. This is a gross injustice, especially as, in the great majority of these cases, no carelessness on the part of the civil examiner can be alleged, and it is patent that he was quite right in declaring the applicant to be up to the standard. Add to this that many recruits who have been examined and passed, but who have subsequently repented themselves of their determination to enter the service, become suddenly lame, blind, deaf, or short winded when they are presented to the dépôt surgeon, and we come to appreciate the fact, that, for a large part of his examining functions the civil practitioner gets nothing. We think that a good case has been made out, for inquiry into the working of the system, and we trust that some Member of Parliament will take the subject in hand, in the interest, if not of the doctors, at least of the military service of our country.

THE forty-fifth annual report of the Governors of King's College Hospital, London, shows a deficit of £2,839, the expenditure having been £15,448, and the total income only £12,609.

POOR-LAW MEDICAL OFFICERS AS CORONERS.

WE drew attention last week to the case of Dr. Parke, of Newtownards, who, while holding the medical officership of the workhouse, had been elected Coroner for North Down, and to the effort of Mr. Sexton, M.P., by means of a question in the House, to induce the Local Government Board to dismiss him from his workhouse appointment. Since that question was put, Col. King-Harman has retaliated by asking the Chief Secretary whether Dr. O'Neill, medical officer of the Athy Union, is the same gentleman who was for some time President of the local Land League; whether he is now Coroner of the Queen's County; and whether, having regard to his duties in that capacity, the Local Government Board will maintain him in the office of a medical officer under the Board? The Chief Secretary replied that the question whether he can hold the two offices is under consideration. The question is precisely similar to one recently put about another person.

It would seem that Mr. Sexton has been hoist with his own petard, and his effort to drive out Dr. Parke has been turned against one of his own protégés. When writing last week we expressed our opinion it would be totally unjustifiable to remove a workhouse medical officer for such cause, and our confidence that if one were so deprived of office a court of law would reinstate him. However it may be contended that it is inconvenient for such officer to be a coroner, it could not be for a moment maintained that his duties in the workhouse are materially interfered with by his holding the second office, and, in any case, the Local Government Board could not reasonably "deem" him "unfit" or call on him to cease from being coroner until some occasion arose in which his medical duties were interfered with by his coronership.

We are disgusted to observe that the Local Government Board is attempting to satisfy Mr. Sexton in this matter by getting Dr. Parke dismissed, though it will not itself take the responsibility of removing him. It has addressed to the Newtownards Guardians a letter, which runs as follows:—

"The Local Government Board are of opinion that it is not a satisfactory arrangement that a medical officer who has charge of a large workhouse infirmary and fever hospital, and who is liable to be called upon at any time to attend sick persons on their admission to the workhouse, should hold another office, the duties of which must take him frequently to a distance from the workhouse, and sometimes out of the union; and in another case, in which a coroner was elected medical officer of a workhouse, the Board declined to allow him to hold that appointment until he resigned the former office. The Board find by the last return furnished to them that there are 347 persons in the Newtownards Workhouse, of whom 86 are sick, and under these circumstances the Board do not think it right that Dr. Parke should be allowed to retain the position of medical officer of the workhouse if he continues to act as coroner; and they must request that the Guardians will be so good as to inform him that if he undertakes to perform duties which are inconsistent with proper and regular attendance upon the sick poor in the workhouse, he must resign the appointment of medical officer."

The quibbling of the Local Government Board is just what might be expected, but we cannot allow it to pass

without comment. They want it to be understood that, having declined to sanction the appointment of a coroner to a workhouse office, they are also entitled to remove a workhouse officer when appointed coroner. They well know that neither they nor the guardians have any such authority, and that there is no analogy between the law of the two cases. It will be noted that they inform Dr. Parke that "if he undertakes to perform duties which are inconsistent with proper and regular attendance upon the sick poor, he must resign." Certainly he must; but until it is proved that his coronership has prevented him doing his workhouse duty he is perfectly safe; and we advise the Guardians or the Local Government Board not to try conclusions with Dr. Parke or any other medical officer under the circumstances. The Guardians have taken a fortnight to consider their reply, and we hope that they will see that to act as the Local Government Board suggests would be both unjust and illegal. In any case they have no power to do more than ask him to resign, which we trust he will not be so foolish as to do, believing as we do that his tenure of office is perfectly secure in law.

Notes on Current Topics.

The Medical Bill.

THE Bill will be introduced in the Lords by Lord Carlingford during the present week in nearly the exact form in which it left the Upper House last session. We regret, if this information be true, that something has not been done to eliminate from it the faults which evoked the opposition, and, we think, the reasonable opposition of the licensing bodies. We have every reason to hope that the Government will be very willing to listen to proposals for amendment, but, nevertheless, it is very unsatisfactory that such proposals should take the form rather of hostile motions in Parliament than of amicable negotiations outside. Alterations effected at the point of the bayonet take time, and are productive of feelings of irritation, and we regret to think that the prospects of the Bill are not advanced by this method of dealing with it.

However, we are well satisfied to learn that the Government are firmly determined on passing it this session, unless something unexpected occurs, and all the more determined because of the attitude of hostility to reform which the Irish College of Surgeons has been induced to assume. If Lord Carlingford refuses to listen to remonstrance on behalf of that College it will have to thank the gentleman who now dictates its policy, and the score of Fellows who have blindly followed his lead, and have thus aided in preventing the needful amendments of the Bill from being secured.

THE abolition of capital punishment appears not to have answered the designs of humanitarians in Switzerland, as we learn that the Government of the Canton of Glaris has just decided by a large majority to reintroduce the death penalty, which was abolished a few years ago.

The Cholera Bacillus.

THE Committee appointed at a recent meeting of the Royal Medico Chirurgical Society, to examine and report on the microscopical preparations obtained from cholera patients, and forwarded by Dr. Straus, of Paris, presented the following report on Tuesday:—"We have examined the microscopical preparations exhibited to the Society on February 12th, 1884, and have found in them the micro-organisms described by Dr. Straus; but do not observe any features of the bacilli in the tissues that can be considered as specific. (Signed) E. Klein, M.D., F.R.S.; Heneage Gibbes, M.D.; Victor Horsley, B.S., F.R.C.S."

Irish Poor-law Superannuates.

WITHIN the past fortnight two instances have occurred illustrative of the great hardship which officers of the Irish Poor Law suffer from the existing system, which empowers a bare majority of a Board of Guardians, for political or religious reasons, to deprive an officer who is incapacitated from performance of duty of any superannuate allowance. Dr. Rawson, of Carlow, was refused a pension by a majority of one, having been disabled by a blow of a stone received four years ago during an election riot. Dr. Rawson had to resign the medical officership of the workhouse and fever hospital after thirteen years of good and zealous service, and is now thrown on the world unprovided for, because he happens to differ in politics from the dominant party.

The Clerk of the New Ross Union, also incapacitated from duty after twenty-three years' service, has been refused a penny of pension or compensation for loss of office by his guardians.

The moral derivable from these cases is that, until the Superannuation Bill passes, union officers should not resign unless they are quite certain of their pension. The guardians have no legal right either to suspend or dismiss them; the Local Government Board could hardly venture to do so, without previously putting pressure on the guardians, and, even then, they would be answerable to public opinion, and to the courts of law for their act. But if an officer finds it totally impossible to hold on to his office, he acts, we think, with excessive indiscretion if he puts himself in the power of the guardians by resigning a month before his pension is discussed. There is nothing whatever in the Act of Parliament to compel him to do so, and it is quite open to him to protect himself by informing the guardians that he is willing to resign if pensioned. Upon this information a friendly guardian can found a resolution, pledging the Board of Guardians to grant superannuation, and the officer can withhold his resignation until the moment that the vote is about to be taken.

If Poor-law officers, by neglect of these precautions, lose their pensions, there will be many to say that the treatment they meet with serves them right.

PROFESSOR RAWDON MACNAMARA has been again unanimously re-appointed the representative of the Royal College of Surgeons, Ireland, on the General Council of Medical Education and Registration of the United Kingdom.

Cold Bathing in Typhoid Fever.

A LENGTHY discussion has just been concluded at the Medical Society of London on the treatment of typhoid fever by the cold bath, and the result is to be regarded as in one sense satisfactorily determining the value of this mode of combating the disease in question. For many years now attention has from time to time been drawn to the subject, and physicians have occasionally recorded their experiences of the advantages ensuing from their adoption of the measure, but there has not previously been any combined authoritative utterance on the main point at issue, such as that which is now published to the profession, and favourable to cold bathing as a means of checking enteric fever. To Dr. Sydney Coupland is due the merit of introducing the question in a paper of unusual merit, and enriched with records of an extensive experience gained in hospital practice. As a final result of his extensive observations, Dr. Coupland arrives at the conclusion that the cold bath, carefully administered, is of undoubted advantage in the class of cases under consideration, and that the deliverance it affords from direct and remote dangers of continued pyrexia entitles it to high regard as a valuable therapeutic agent. Although, however, the majority of those who joined in discussion of Dr. Coupland's paper agree with him in this conclusion, still some, and notably Dr. Bristowe, express doubt as to the wisdom of a proceeding which on theoretical grounds may be followed by dangerous consequences to the patient. The worst of these evils is, of course, the risk of hæmorrhage following congestion of the viscera from application of cold externally; but Dr. Coupland has also recognised the possibility of such complications, and has expressly advised caution in any case where they may suggest themselves in the condition of the patient. In other respects, and on the primary question of the importance of antipyretic treatment of some kind in cases of fever, there is, it may safely be assumed, a consensus of opinion in the profession; but it will probably long continue to be the fact, that notwithstanding a large accumulation of statistical evidence in its favour, some physicians will hesitate to be convinced that cold water is an appropriate remedy for use against typhoid fever. At present we may be content with the verdict which has been registered, at any rate by a majority, to the effect that such treatment is worthy of adoption, and offers a good prospect of successful results.

Army Medical Department.

BRIGADE-SURG. EUGENE FRANCIS O'LEARY, M.D., retired, has been granted the honorary rank of Deputy Surgeon-General. The undermentioned Surgeons on probation to be Surgeons:—Oswald George Dyx Bradshaw, Michael Kelly, M.D., Horace Henderson Pinching, Robert James Geddes, M.B., William Kelly, M.D., David Valentine O'Connell, M.D., Anthony Dodd, George Wilson, M.B., James More Reid, Thomas Bassell Winter, Frederick Samuel Heuston, Robert James Anderson Durant, George Frederick Gubbins, James Perceval Myles, Robert Lealy, M.B., Henry Priestley Birch, Monckton O'Dell Braddell, M.B., James John Conway Donnet, Henry Maxwell Sloggett, Clement Sumner Robinson.

The City of Dublin Coroner.

THE proceedings of the City of Dublin Coroner when presiding last week at the inquest held at St. Vincent's Hospital make manifest a misconception of his functions by him which needs to be corrected, especially as we have had on more than one occasion to animadvert upon similar displays of bias by this gentleman. Dr. Whyte seems to labour under the misapprehension that it is his function to act, from his judicial seat, as advocate, judge, jury, and public lecturer in general, and, in this idea, he occupies the time of the Court with a variety of speeches, satisfactory, no doubt, to himself, but not as greatly appreciated by his audience or the public. In this particular instance he favoured the jury with his own opinions on the legal and moral aspects of post-mortem examinations, the advantages to science therefrom, and the proper method of certifying causes of death, and in the "exuberance of his own verbosity" he seems to have forgotten that he is paid to investigate causes of death, and to prevent the inquiry wandering outside that limit. However interesting Dr. Whyte's views may be, they were not asked for, and they served no purpose save to delay the inquiry, secure for him a little popularity amongst the lower classes at the expense of his own profession, and display his complete ignorance of the law respecting post-mortem examinations, the necessity of such examinations for scientific purposes, and the law of death-registration.

Dr. Whyte's character as a scientist, or as a medical practitioner, or as a legal authority, will hardly suffice to convince pathologists that nothing is to be gained by autopsies; but his dictum that every medical practitioner should certify causes of death on his belief and without investigation explains the fact that in the City of Dublin numbers of suspicious deaths occur respecting which no inquests are held, the "belief" of the nearest policeman being accepted by the coroner as abundant proof of the cause of death. A policeman's belief acquires great cogency in places where the coroner is paid by salary, and, without doubt, it affords a ready means of limiting the number of inquests which that functionary is required to hold, but we assert that, in point of law, such evidence of cause of death is waste paper, and that it is a gross abuse that suspicious deaths should escape investigation by the operation of Dr. Whyte's theory of registration law.

Prize Essays on "Housing the Poor."

THE Society of Arts announces that one of the members of the Society, Mr. William Westgarth, has placed at the disposal of the council a sum of £1,200, to be awarded in prizes for essays on Dwellings for the Poor, and the Reconstruction of Central London. Competitors for these prizes are required to send in their essays, addressed to the Secretary of the Society of Arts, John Street, Adelphi, not later than December 31st, 1884; and each essay must be printed, and accompanied by all necessary maps, plans, drawings, &c. The effect of this munificent offer will probably be to stimulate an interest in the great question of housing the poor among a class of men whose aid in solving the problem will be highly valuable, and who, but for the prospect held out by the offer of an immediate reward, might not be induced to devote the time and attention necessary to full consideration of the

subject. So practical a proposal as that the Society of Arts has thus been enabled to make affords also a certain proof of the material sympathy felt in the movement on foot to improve the condition of our poor by those who are in a position to give such demonstrations of their willingness to assist in it.

The Clinical Society's Investigation on Myxœdema.

THE Honorary Secretary of the Committee appointed by the Clinical Society to investigate Myxœdema asks us to state that the Committee have drawn up a schedule of inquiry, and that a copy will be forwarded to any member of the profession who has had cases of this disease under his care, on application to Dr. Hadden, 21 Welbeck Street, London.

Communicability of Rabies.

M. PASTEUR made an interesting communication to the Paris Academy of Sciences on February 26th, in relation to canine madness. He stated that the disease could be communicated to a dog by inoculation with fragments of marrow or of nerve taken from a mad dog. He also stated that he had rendered twenty dogs proof against the disease by inoculating them with a modified virus.

Legal Insanitation.

A CURIOUS illustration has been afforded in the law courts of the conflict between sanitary law and statute-book law, and which very clearly exhibits the amount of injury that may be done from the absence of amendments in legislation rendered imperative by advance in scientific knowledge. The incident referred to arose out of a case in which the plaintiff sought compensation for the pollution of a well by sewage draining into it from an adjoining well which the owner had ceased to use as a source of water supply, and had converted into a receptacle for house refuse. The law of the land most carefully provides against any interference with surface streams, either in the way of pollution, diminution, or diversion; but while thus properly particular with respect to water flowing *along* the land, it entirely omits to protect that which runs *beneath* the surface; so that it is open to any one to interfere with a spring or other source of supply, provided such interference does not commence at the surface level. In the case referred to, therefore, though by the action of the defendant the plaintiff's drinking water was absolutely poisoned, no remedy was possible against the offence; and the learned judge, while compelled to dismiss the case, very properly commented on the injury arising from the existence of a law so detrimental to the health interests of the community. It is inconceivable what amount of mischief may not thus be done, and which, while entirely preventible, may still be persisted in so long as no legal impediment exists to stay it. The facts made public in this connection have clearly shown a need for immediate reform; and it may be hoped that this will be insisted on now that the hurtful nature of the consequences that can arise under present conditions has been demonstrated.

Condensed Milk.

SEVERAL successful prosecutions have been conducted against the retailers of condensed milk in Liverpool, which will doubtless cause considerable consternation among the large milk condensing companies, who have up to the present time escaped the operations of the Sale of Food and Drugs Act.

The *Analyst* says that condensed milk has been lately extensively employed in connection with what may be called a new industry, that of "milk blending," or, in other words, letting down rich dairy milk, so that the analytical results agree with the figures for solids not fat prescribed by the Society of Public Analysts. Large quantities are daily consumed in this way by milkmen, and to such an extent has the trade increased that condensed milk is imported in churns, especially manufactured for the convenience of dairymen, these churns being returned to the factory for a further supply.

The Dublin Zoological Society.

THE annual report, which has been issued to the members, exhibits the Society in a condition of decadence and impecuniosity, for which its normal position of semi-bankruptcy hardly prepared us. If the Society be not liquidated, and the collection of animals sold out before the end of the present year, it is to be hoped that an energetic effort will at last be made to rescue from the mismanagement of the Council an institution which has all the elements of success, and which might fulfil a useful educational function if the most moderate amount of discretion and care were exercised in working it.

The Gardens have within the past year lost no less than one fifth of their visiting constituency, the admissions at the gate having been 20,000 less than the previous year. The Sunday admissions—which represent the patronage of the poorer classes—have fallen off within the year 25 per cent, and their money value is now worse than it has been at any period for ten years past. When neglect and mismanagement have, in times past, brought the Society into a similar condition, it has been the wont of the Council to fall back upon dog shows, skating tickets, clamorous begging for subscriptions, and even upon a levy from the private purses of the Councillors. From the Dog Show of the year 1883, £153, and from Skaters £75, have accrued to the Society, but, in spite of this adventitious income, the year ends with a deficit of £540, and a further loss of £55 to the reserve fund.

This unhappy state of affairs has been brought about by the ruinous policy of doubling the price of admission without in any way increasing the attractions of the Gardens. The Council seems to consider that it has no function but to attend once a week for the purpose of eating a breakfast and registering the decrees of the Honorary Secretary, and an annual shuffling of the cards takes place, by means of which every Councillor who ventures to show his independence of this control is quietly got rid of, and his place filled by some one who will not be likely to have a will of his own. Such a system can only be justified by success and prosperity, but it has produced disaster and insolvency, and we

again say that the hour has come for a rescue of the Society from the hands of those who have, despite all warning and remonstrance, brought it to such a condition.

The Patent Medicine Stamp Act.

A CASE of considerable interest and importance has recently occurred, which places the construction of the Act upon a very definite basis, and shows that although it is a source of considerable wealth to the Revenue, that end is not always attained at the expense of the public, as is generally imagined. We have now before us the correspondence between the Commissioners of Inland Revenue and a firm of drug manufacturers, Messrs. Christy and Co., relative to the manufacture of Menthol and its sale as a curative agent in facial neuralgia, &c. This drug was issued in cones saturated with wax, not for the purposes of adulteration, but as a vehicle for fixing the Menthol, and as a preventive of skin irritation. The Commissioners threatened prosecution unless the sale of the article were immediately stopped and stamp duty paid for every ounce which should henceforth be sent out. The manufacturers explained that but 10 per cent. of wax, and this not for the purposes of adulteration, was used in the process, and that they were anxious that the article should not be classed as a patent medicine. But the Revenue authorities were inexorable, nothing but the pure drug, without the semblance of admixture or vehicle, could be allowed to evade the operation of the Patent Medicine Stamp Act, and a fine of £10 for every bottle or package sold otherwise than in strict accordance with these provisions would be enforced. With this decision before them the manufacturers have wisely decided to send out the Menthol in cones without any vehicle. We would prefer to hold the charitable view that in thus insisting upon an unadulterated drug the authorities had only the interests of the profession and public at heart; but we are perforce drawn from this issue to the more likely one that they have an inherent weakness and interest in dragging every remedy, good, indifferent, or bad, to the level of a three-halfpenny fee, leaving the public to protect itself as best it may. Logically, it should follow from this decision that only adulterated drugs are subject to the Act, and that all pure articles are exempt; it would much simplify matters if this were so.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From whooping-cough, 1.9 in Bolton, and 1.5 in Manchester; from scarlet fever, 3.3 in Leeds, 1.6 in Preston, and 1.4 in Manchester; from measles, 2.5 in Nottingham, 2.4 in Derby, 2.1 in Oldham, and 1.9 in Salford; and from "fever," 1.4 in Plymouth. The 38 deaths from diphtheria included 14 in London, 6 in Glasgow, 3 in Edinburgh, 3 in Liverpool, 3 in Hull, 2 in Manchester, and 2 in Newcastle-upon-Tyne. Small-pox caused 4 deaths in London, 3 in Birmingham, 2 in Sunderland, 1 in Liverpool, and 1 in Newcastle-upon-Tyne.

Subcutaneous Injection of Iron.

EXPERIMENTING on the behaviour of iron within the animal system Dr. Glaesoeke, reports in the *Archiv für Experimentell. Pathologie und Pharmacol.*, B1. 17, Heft. 6, that he has found the ferium citricum oxydatum to be the best form of iron for subcutaneous injection. No reaction takes place at the site of the puncture. The iron is excreted through the kidneys, not through the glomeruli, but through the epithelium of the tubuli uriniferi. The excretion is complete within twenty-five hours. The liver to a greater extent takes part in the elimination. The injections are made in the long dorsal muscles or in the nates. The solution should not be more than one month old, and for adults doses of $1\frac{1}{2}$ grains in a 10 per cent. solution are recommended.

In the case of an extremely chlorotic girl, in whom the proportion of hæmoglobin in the blood was 38 per cent. of the normal, it rose after fifty-four injections to 82 per cent., and the patient had in the meantime gained sixteen pounds in weight; the menses also, which had been absent for nine months, returned. Good results were also obtained in a case of secondary anæmia from hæmorrhage from the stomach.

If too much iron be injected toxic effects may be manifested, in the shape of general *malaise*, vomiting, and weakness. Diarrhoea may also come on.

Hydrastis Canadensis in Uterine Diseases.

PROFESSOR SCHATZ, of Rostock, who, if we are not mistaken, has removed the whole uterus at least ten times, reminds one-sided knife gynecologists, in the *Deutsche Med. Zeitung*, that in addition to an operative treatment of uterine diseases there is also a method of treatment by medicine, and that, if this be followed out sufficiently, good results will be obtained, to lessen the frequency of dangerous and maiming operations. There are especially functional disturbances of the uterus and ovaries, anomalies of menstruation, direct or reflex or simply congestive disturbances, which exclude operation and call for medication. That happiness is not alone to be achieved by the aid of the knife the *hydrastis canadensis* has given to the writer a striking proof. This drug, which has only been employed by the writer in the form of the fluid extract (Parke, Davis & Co.), contracts blood-vessels and thus diminishes congestion of the genital organs. In long-continued or large doses it diminishes the frequency of menstruation; the flow is also diminished and pain is lessened and often removed entirely in vaginal hæmorrhage and dysmenorrhœa that has no local cause, as well as in diseases of the uterus and its neighbourhood. Its effects are noteworthy in many myomata, the hæmorrhage occasioned by them being much lessened and sometimes entirely prevented. He generally gives twenty drops of the fluid extract four times daily, not only whilst hæmorrhage is actually present, but in preference a week before the anticipated painful or profuse menstruation. This drug occasionally, after lengthened employment, improves the appetite.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 32,

Bombay 29, Madras 52, Paris 25, Geneva 28, Brussels 27, Amsterdam 27, Rotterdam 33, The Hague 19, Copenhagen 20, Stockholm 27, Christiania 24, St. Petersburg 40, Berlin 23, Hamburg 24, Dresden 25, Breslau 28, Munich 28, Vienna 26, Prague 38, Buda-Pesth 30, Trieste 36, Rome 29, Turin 43, Venice 30, Lisbon 40, New York 23, Brooklyn 19, Philadelphia 26, and Baltimore 20.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 21.1 per 1,000 of their aggregate population. The death-rates in the several towns were:—Portsmouth 14; Hull 15; Wolverhampton, Brighton, Leicester 16; Bristol 17; Bradford, Birmingham 18; Plymouth, Derby, Sheffield, Sunderland 19; London, Cardiff, Birkenhead, Blackburn 20; Salford, Preston, Huddersfield, Edinburgh 21; Norwich, Liverpool 23; Oldham 24; Glasgow, Newcastle-on-Tyne 25; Bolton, Halifax, Leeds, Nottingham 26; Dublin, Manchester 30.

The Medical Sickness, Annuity, and Life Assurance Society.

THE success which has attended the formation of the Medical Sickness, Annuity, and Life Assurance Society at so early a period of its development, when the profession as a whole have hardly acquired a knowledge of its existence is in the highest degree satisfactory. Over forty gentlemen in various parts of the kingdom have consented to act on the general committee, and from their number a provisional executive committee, which has already held several meetings, has been formed.

The advantages offered to those who assure in this Society are as follows:—1. A certain sum per week (from 2 to 4 guineas), according to amount of premium, during illness. 2. Annuity after 65 years of age. 3. A certain sum at death.

The Society is based on principles of purely mutual assurance, the whole of the funds becoming the property of the members, whose liability is strictly confined to the quarterly premiums. The Society will be registered under the Friendly Societies Act.

It cannot be too widely known that this Society, which took form at a meeting held during the session of the British Medical Association at Liverpool, had no direct connection with that body, but is open to all registered medical practitioners in the United Kingdom.

The number of gentlemen who have joined is already sufficient to augur well for its future success. The opinion of Mr. Nelson, F.I.A., as a leading actuary, has been obtained on the Rules and Tables, and after examination he has certified that in his opinion they form a sound basis for the work of the Society. Copies may be had of the Secretary, Mr. J. C. Radley, at the temporary offices of the Society, 26 Wynne Road, Brixton, S. W.

The County Kerry Infirmary.

THE long-fought battle between Drs. Neligan and Fitzmaurice for the surgeoncy of the Tralee Infirmary has come to a termination unsatisfactory to all parties. The question in dispute was whether two or three of the voters who carried Dr. Neligan's election were or were not entitled to vote, and this question turned upon whether they had paid their subscriptions sufficiently early to entitle them to do so. The statute provided that no payment should be valid

unless made before the vacancy occurred. These payments were made after Dr. Lalor's resignation had been sent in, but before it was formally accepted, and the disputed point, therefore, was what constituted the vacancy—the resignation or the acceptance of it.

After prolonged litigation, the judges have declared that the resignation makes the vacancy, and that, therefore, Dr. Neligan's votes were bad, and they unseated him, but they expressly declared that they would give no judgment as to whether his opponent Dr. Fitzmaurice was or was not duly elected, inasmuch as a still more difficult legal question as to the number of the quorum had arisen.

Thus the infirmary is without a surgeon. The competitors are both out in the cold, until a further suit settles their claims, and, worst of all, they are obliged to pay their own costs.

THE MEDICAL BILL.

DEPUTATION FROM THE ROYAL COLLEGE OF SURGEONS IN IRELAND TO THE LORD LIEUTENANT.

A DEPUTATION, consisting of the President, Dr. Wheeler, and of Drs. Kidd, Barton, Hamilton, MacNamara, Colles, and Hughes, waited on His Excellency on Monday, at 12.30, to submit to him the views of the College as pronounced by the recent meeting of the Fellows in regard to the Medical Bill.

The deputation having been introduced by the President, Dr. Kidd addressed His Excellency at much length, and submitted the arguments in favour of multiple qualifications of various grades as against a single one of uniform grade throughout the Kingdom. He also urged the views expressed in his letters to our columns in favour of coadjutor examiners. "The College," he said, "would urge His Excellency to use his influence to prevent the carriage of that part of the Bill which would render their College useless."

Mr. MacNamara pointed out that the College was willing to have the Medical Council reconstituted. He urged that funds should be reserved to enable the College to maintain its museums, libraries, &c.

Mr. Barton stated that they did not come there to forward any scheme other than that in the Bill.

His Excellency, in reply, said:—

This Bill was introduced last year upon the report of a commission which was appointed through his recommendation to Her Majesty. In electing the members of the commission every endeavour was made to get the most eminent men—not only professional men, but those who knew the wants of the country. No able men could be found than the Bishop of Peterborough, Mr. Cogan, and Dr. Robert McDonnell. Another eminent man who also consented to act at his (the speaker's) earnest request was the late English Master of the Rolls, Sir George Jessel. He knew Lord Carlingford was anxious that all interests should be considered, and that the question should be settled on a sound and just basis. He considered there was a great deal of unnecessary alarm existing about this Bill, and felt certain that the Government never intended to bring to uselessness a body which had done so many eminent services as the Royal College of Surgeons. They believed, he was sure, the utility of that body would still remain, and that it would do as much service to Ireland and the medical world in the future as in the past. He did not gather that the commission wish to bring all education to a dead level, and do away with all competition between the various bodies. That was the view (his Excellency continued) with which he approached the subject, and the view he still entertained, and he would be extremely sorry if in any bill introduced by Her Majesty's Government principles like this were lost sight of. The Government were most anxious to get this question settled, and Lord Carlingford also desired to press forward the measure, and, if possible, carry it this session. The objections which had been made by the members of this deputation and others Lord Carlingford would be most ready to consider, and, no doubt, in several matters alterations would be made. But he was afraid he could not encourage them to think that the Bill would be withdrawn, as it was most desirable in the interests of everyone connected with the profession that it should be passed into law. As to the question of assessors,

these assessors were appointed by the Royal College of Surgeons, and had been most successful. But it did not follow that because assessors appointed by the College were successful others appointed by the Government could be equally so, and therefore he was afraid there was an overwhelming objection to the adoption of the suggestion made by the deputation in this matter.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 23rd ult., was 107, and the death-rate 23 per 1,000. Diseases of the chest accounted for 50 deaths, and zymotic causes for 10, of which 1 was due to fever, 2 to scarlatina, and 4 to measles, the intimations of these diseases for the week being 4, 29, and 107.

EDINBURGH—ROYAL HOSPITAL FOR SICK CHILDREN.—The directors of this hospital, at their meeting on the 25th ult., elected Dr. James W. B. Hodsdon, M.D., M.R.C.P.E., F.R.C.S. Edin., to be an extra-physician in room of Dr. John Playfair, who was recently promoted to be an ordinary physician.

MEDICAL PRELIMINARY EDUCATION.—We are of those who believe that the present system of medical education is indefensible, that commercial interests rather than the public good is the regulating power, and that notwithstanding the ostensible stringency of examinations, the medical profession is crowded with men of the most rudimentary educational accomplishments. Anyone who comes in contact with junior medical students cannot fail to observe this. As examples of original spelling we take at random from the case-book of a large hospital north of the Tweed the following, viz., "*absis*," "*askitis*," "*ophthalma*," "*3ss. ter in die post sibia*." The common word "*phthisis*" forms a veritable *pons asinorum*, and the numerous ways in which it is spelt are truly amusing; but for downright humour and ingenuity commend us to the acquaintance of the student who noted that a patient was suffering from "*Annie Sarky*!" (*anasarca*).

GLASGOW DEATH-RATE.—The deaths in Glasgow for the week ending with Saturday, the 23rd ult., were at the rate of 25 per 1,000 per annum, as compared with 25 in the preceding week, and 33, 25, and 27 in the corresponding weeks of 1883, 1882, and 1881.

SCOTCH VITAL STATISTICS.—From the official returns of the Registrar-General for the week ending Saturday, Feb. 23, we learn that the death-rate in the eight principal towns was 22·6 per 1,000 of estimated population. This rate is 4·8 below that for the corresponding week of last year, but 1·7 above that for the previous week of the present year. The lowest mortality was recorded in Perth—viz., 11·8 per 1,000; and the highest in Glasgow—viz., 24·9 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3·2 per 1,000, being 0·2 above the rate for last week. Acute diseases of the chest caused 108 deaths, being 5 less than the number for last week.

EDINBURGH UNIVERSITY TRICENTENARY CELEBRATIONS.—The provisional arrangements in connection with the celebration of the tricentenary of the Edinburgh University were submitted at the Edinburgh Town Council on Thursday last by the Lord Provost's Committee. The celebrations are to extend over three days—the 16th, 17th, and 18th April; but on the evening of the 15th (Tuesday) the Lord Provost, Magistrate, and Council will hold a reception in the Museum of Science and Art to welcome to the city the distinguished visitors and others expected to be present at the University

celebrations. The celebrations proper will be begun on the Wednesday forenoon (16th) by a religious service in St. Giles's Cathedral. In the afternoon there will be the formal opening of the new University buildings. It has not yet been decided by whom the opening ceremony will be performed, but an effort is being made to secure the presence of a member of the Royal Family. In the evening there will be a reception by the University authorities in the University library. On the following day there will be a graduation ceremony at eleven o'clock, a reception by the Faculty of Advocates in the afternoon, and in the evening a banquet will be given in the Drill Hall, Forrest Road. The programme for the concluding day of the celebrations will include the visitation by the strangers of the places of interest in Edinburgh and neighbourhood, a students' concert (afternoon) in the Music Hall, and a students' ball and probably a partial illumination of the city in the evening. A committee has also been appointed to draw up a list of names of citizens who would be willing to accommodate some of the distinguished strangers during their stay in Edinburgh.

Obituary.

DR. ALEXANDER WOOD, OF EDINBURGH.

THIS gentleman, whose death last week was somewhat sudden and unexpected, occupied at one time a prominent position as a physician in Edinburgh. He sprang from a medical stock, and was from boyhood imbued with the principles and practice of medicine. He graduated at the Edinburgh University in 1839, and commenced private practice at a very early age. The following year he became a Fellow of the Royal College of Physicians, and was henceforth identified with that Corporation, both in its educational capacity and as representative of its interests in the General Medical Council. A man of fine presence and singularly able debating powers, he was for sixteen years present in London at all the meetings of that body, conducting the business pertaining to his office with the zeal of an earnest advocate and the power of a born orator. During his tenure of office in the Medical Council he was almost invariably opposed by the late Sir Dominic Corrigan, and these two giants in rhetoric and fencing seemed never so great or so much at their ease as when attacking each other and the Colleges of which they were the representatives on this Council. Some twelve years ago Dr. Alex. Wood retired from the practice of his profession, and has since devoted much time to education, to the improvement of the social condition of the working classes, and to the promotion of tramway schemes in Edinburgh, from the latter of which he was known to derive a very considerable income. An Edinburgh lay paper speaks of him as a man who was fond of having his own way, and, when this was not obtainable, he let his enthusiasm get the better of his judgment. We, however, prefer to speak of him from personal knowledge as a courageous but gallant opponent—one who was combative by nature, but chivalrous to an opponent, and the first to shake hands when beaten.

Correspondence.

MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to the correspondence relative to medical reform in your columns, the following remarks may not be inappropriate:—In the competition for the public services the graduates from all licensing corporations meet on equal terms; and as the army draws the greatest number, I have taken from the lists from 1862 to 1883 inclusive the names and qualifications of the two gentlemen at the head and of the two at the bottom of the ranks for each examination in this period. There are 66 in each category. In the case of an individual who belongs to two corporations I give the first registered as the one to which the owner is assigned, and I find the facts to be as follows—viz., the College of Surgeons

of England gave 20 to the top rank, and 10 to the bottom; the English Universities 4 to the top and 1 to the bottom; the Scotch Surgeons 5 to the top, and 6 to the bottom; the Scotch Universities 11 to the top, and 12 to the bottom; Dublin University 7 to the top and 7 to the bottom; the Queen's University of Ireland 14 to the top and 8 to the bottom; the Dublin College of Surgeons 5 to the top and 22 to the bottom. It will thus be seen what qualifying bodies produced the highest percentage of good and also of mediocre men at the army test. Genuine medical reform should be directed towards obtaining Poor-law, lunacy, and prison medical officers through an open competitive examination from all graduates, promoting to inspectorship through the respective departments, and leaving the teaching and licensing bodies free. The public will select the fittest in their own instance according to fancy and judgment.

Yours faithfully,

J. ROCHE, M.D., Retired Indian Medical Service.

Mount Clarence, Kingstown,
Feb. 28th, 1884.

Medico-Parliamentary.

HOUSE OF COMMONS.

ARMY MEDICAL SERVICE.

On Thursday last, Mr. GIBSON asked the Under Secretary of State for India, had any, and what, steps been taken since last August by her Majesty's Government to meet the grievances of the Indian Medical Service, and to lessen the dissatisfaction which existed in all its ranks.

Mr. J. K. CROSS.—Last year I stated, with a view to the gradual removal of the existing disadvantages to the Indian Medical Service of having more officers than there were substantive posts for them to fill, the number of annual appointments would be reduced to the lowest pitch compatible with justice to existing students and the future efficiency of the department. This measure is still being carried out. Only ten appointments were made to the service last year, and only ten will be made this year. It is not proposed to take any other step but this, which must prove effectual in adjusting a due proportion between the number of changes and of officers to hold them.

FEVER HOSPITAL AT WINCHMORE HILL.

On Friday, Lord G. HAMILTON complained that the action of the Local Government Board in declining to hear the objections of the inhabitants of Winchmore Hill, expressed through their local sanitary authority, against the establishment of a fever and small-pox hospital in their district, was a course calculated to bring the principle of self-government into disrepute, and to establish a dangerous precedent for the exercise of that controlling power over local boards entrusted by Parliament to that department. He said the local authorities complained that the Local Government Board had treated them with discourtesy in refusing them a hearing on a matter so intimately connected with the health of a populous district.

Mr. G. RUSSELL said the Local Board expressed their views and set forth their objections on paper, but they did not ask that any deputation might be received by the Local Government Board. On the 19th of January, the Metropolitan Asylums Board decided to acquire the site, and when the Southgate Board applied for an interview by deputation it was too late. No discourtesy was shown by the Local Government Board, and none was intended. With regard to the decision, the time always came when the administrative authorities must strike the balance between the contending parties. It was almost impossible to choose a site that would please everybody in cases of this kind. Local dissatisfaction or prejudice could not be weighed against the substantial advantages secured to the health of the metropolis by approbation of this scheme.

DR. WODEHOUSE OF DONEGAL.

On the Votes for Supply, Mr. O'BRIEN moved the reduction of the Vote by £247, in respect to the salary of Dr. Wodehouse, the inspector of the Poor Law Board in Donegal, whom he accused of misrepresenting and minimising the distress in that county last summer.

Mr. TREVELYAN defended the character of Dr. Wodehouse,

who, he said, was an energetic and intelligent official, extremely faithful to his duty.

The Amendment was negatived without a division.

University of Cambridge.—The following have been elected members of the Board of Electors to the undermentioned professorships until February 20th, 1892:—Chemistry, Professor Dewar; Anatomy, Dr. Paget, Professor of Physic; Botany, Professor Michael Foster; Jacksonian Professorship, Professor Liveing; Zoology and Comparative Anatomy, Professor Michael Foster; Downing Professor of Medicine, Dr. T. Lauder Brunton, Edinburgh; Physiology, Mr. J. N. Langley, Trinity; Pathology, Dr. Latham, Downing Professor of Medicine; Surgery, Mr. Timothy Holmes, Pembroke. Dr. Hans Gadow, Strickland Curator, has been approved as a teacher of Comparative Anatomy; Mr. Laurence Humphry, M.A., M.B., Trinity, as a teacher of Pathological Anatomy; and Mr. E. H. Neville, Sidney-Sussex, as a teacher of Practical Chemistry.

Royal Medical and Chirurgical Society of London.—The following is the list of officers nominated for 1884-85:—President: *George Johnson, M.D., F.R.S. Vice-President: *William Overend Priestley, M.D.; Reginald Thompson, M.D.; Richard Barwell; William Scovell Savory, F.R.S. Treasurers: Charles B. Radcliffe, M.D.; John Cooper Forster. Secretaries: Richard Douglas Powell, M.D.; Matthew Berkeley Hill. Librarians: Wilson Fox, M.D., F.R.S.; John Whitaker Hulke, F.R.S. Other members of Council: G. F. Blandford, M.D.; Dyce Duckworth, M.D.; Samuel Jones Gee, M.D.; F. W. Pavy, M.D., F.R.S.; *C. Theodore Williams, M.D.; *John Croft; *Sir William MacCormac; *J. Pickering Pick; *William Sedgwick; William Spencer Watson. Those gentlemen to whose names an asterisk is prefixed were not on the Council, or did not fill the same office last year.

The Hospitals Association.—The first Council of the Association has been constituted as follows:—Vice-Presidents: The Right Hon. Lord Aberdare, F.R.S., Hospital for Sick Children; Sir T. Fowell Buxton, Bart., London Hospital; Sir Andrew Clark, Bart., LL.D., M.D., London Hospital and East London Hospital for Children; Major Ross, M.P., Middlesex Hospital. Council: The Right Hon. the Earl of Cork and Orrery, K.P., St. George's Hospital; Viscount Powerscourt, K.P., Ireland; Sir Rutherford Alcock, K.C.B., Westminster Hospital and Hospital for Women; H. W. D. Acland, Esq., M.D., C.B., D.C.L., F.R.S., Oxford University; William Bousfield, Esq., King's College Hospital; J. S. Bristowe, Esq., M.D., F.R.S., St. Thomas's Hospital; Henry C. Burdett, Esq., Seamen's Hospital and Home Hospitals Association; J. H. Buxton, Esq., London Hospital; M. D. Chalmers, Esq., London Fever Hospital; The Rev. Canon Erskine Clarke, M.A., Bolingbroke House Pay Hospital; Frederick Cox, Esq., Chelsea Hospital for Women and British Lying-in Hospital; W. H. Cross, Esq., St. Bartholomew's Hospital; H. N. Custance, Esq., Metropolitan Hospital Sunday Fund; R. Farquharson, Esq., M.D., M.P., Scotland; Timothy Holmes, Esq., St. George's Hospital and Provident Dispensaries; R. Benson Jowitt, Esq., General Infirmary, Leeds; G. B. Lloyd, Esq., General Hospital, Birmingham; R. H. Lloyd, Esq., M.D., Lambeth Infirmary; Charles Macnamara, Esq., F.R.C.S., Westminster Hospital; Malcolm Morris, Esq., St. Mary's Hospital; C. T. Murdoch, Esq., Great Northern Central Hospital; William J. Nixon, Esq., House Governor, London Hospital; Richard Quain, Esq., M.D., F.R.S., Consumption Hospital, Brompton; T. Gilbert-Smith, Esq., M.D., London Hospital and Royal Hospital for Diseases of the Chest; Joseph White, Esq., F.R.C.S., General Hospital, Nottingham.

Notices to Correspondents.

DR. J. KENT SPENDER (Bath), MR. H. A. REEVES (London), DR. MCNAUGHTON JONES (London), DR. CLARK (Bothwell), and DR. MARTIN (Sheffield) will please receive our thanks.

DR. T. E. CAHILL.—We believe the staff at the hospital referred to do not issue a volume of "Hospital Reports." Neither the staff nor the hospital is large, and it is probably a question of expense which has hitherto prevented these reports being accessible, except in fragments as they appear in one or other of the medical journals.

LARGE IMPORT OF LIME JUICE.—The demand for lime juice 1 apparently on the increase, as is evidenced by recent enormous impor-

tations at Liverpool. The *Journal of Commerce* says:—The *Itida* has just arrived from the Island of Montserrat with 40,000 gallons, making already the unprecedented total this year of 90,000 gallons, the whole of which is consigned to one firm.

THE ROGERS TESTIMONIAL FUND.

THE promoters of the expression of opinion of Dr. Joseph Rogers' public work, during upwards of thirty years, desire to inform the profession and the public that the subscription list will remain open until the end of March. The following additional subscriptions have been received since the publication of the last list in these columns:—

Albert Southey, Esq.	£1 1 0	H. T. Word, Esq.	£2 5 0
Dr. E. S. Willett	1 1 0	Dr. T. Morgan	0 5 0
Messrs. Pinching	0 10 6		

MR. W. COLLINS.—The subscription in the United Kingdom is one guinea per annum, post free; to the Colonies, £1 8s. 6d.; and to India, £1 6s., post free. We have directed the publisher to send you subscription form.

DR. FRANCISCO PATINO (Mexico), DR. HARTLEY (East London, South Africa).—Our exchange list is already too full; regret we cannot increase it at present.

B. C. T. asks: 1. Is salicine soluble in water? What is the usual dose? How is it usually prescribed, whether in mixture or in powder? 2. Is it safe to syringe the ears of a child, at six months, for otitis?

[1. Salicine is freely soluble in water, and can be prescribed in a mixture with drachm doses of syrup of orange peel, to cover the bitter flavour. In rheumatic fever (the disease in which it is principally employed) it is usually commenced in twenty-grain doses every third hour; but sometimes so much as sixty or even eighty-grain doses are required at similar intervals. The reduction of temperature shown by the clinical thermometer is the surest test that a sufficient dose has been attained. Salicine may also be given wrapped up in wafer paper, or dissolved in milk. This latter is a capital means of administering either salicine or quinine. 2. Certainly. —Ed.]

F.R.C.S. ENG.—We shall be careful to make the full proceedings known as early as possible. It is not probable that the fears you give expression to are founded on any certain knowledge. When the modifications are announced it will be sufficiently early to take steps for ensuring complete representation.

DR. LEWIS.—According to current reports, issued under authority, no one has succeeded in solving the difficulty. But there is no provision of the kind you mention; so that you have either been misinformed or intentionally deceived.

ST. JOHN AMBULANCE ASSOCIATION.

THE large railways in India and the Colonies are devoting attention to the importance of ambulance instruction for their employees. In India, classes in connection with the Bombay Centre of the St. John Ambulance Association have been formed on the E. B. & C. I. Railway; and in Canada a meeting has been called, at Montreal, for the same purpose on behalf of the Grand Trunk R. R. officials. Certificates have lately been presented at Gravesend by Mr. V. Barrington Kennett, at Herford by Baroness Dimsdale, and at Watford. Meetings to form new branches have been held at Nuneaton, and at Devonport, the latter presided over by General Sayer, C.B., commanding the Western District, and largely attended by the officers and men of the troops in garrison.

DR. CHICKERING.—The custom does not obtain in this country; moreover, it is of so extraordinary a nature that we find some difficulty in imagining it can be commonly observed in any civilised State. If you can provide us with something more tangible than hearsay evidence we shall be willing to investigate the subject with a view to verifying it.

THE PRIZE FOR NON-ALCOHOLIC BEVERAGES.

SINCE the publication of the paragraph in our last issue to the effect that a prize, or prizes, of the value of about £70 and £50, is to be offered for a cheap and palatable non-intoxicating beverage, we have had numberless inquiries for particulars, and not being fully in possession of the necessary details, we wrote to Dr. Norman Kerr, who is *au courant* with everything that transpires in the ranks of abstention, and that gentleman replies as follows: "The project is not yet matured. As soon as the necessary funds have been raised, the conditions of the competition will be advertised." In thanking Dr. Kerr for his reply, we would at the same time ask our many correspondents to accept it as an answer to their queries.

Meetings of the Societies.

WEDNESDAY, MARCH 5TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Flower, On the Principal Types of the Human Species.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown by Dr. Horrocks and others.—Dr. John Williams, On the Corroding Ulcer of the Os Uteri.—Mr. Alban Doran, On the Relation of Prolapse of the Vagina to Hernia, illustrated by two Pedigrees.

THURSDAY, MARCH 6TH.

ROYAL INSTITUTION.—At 3 p.m., Professor Tyndall, On the Older Electricity.

HARVEIAN SOCIETY.—At 8.30 p.m., Mr. Lawson Tait, On some Recent Advances in Pelvic Surgery.

FRIDAY, MARCH 7TH.

ACADEMY OF MEDICINE IN IRELAND (Surgical Section).—At 8 p.m., Living Specimens by Dr. Baxter, Mr. Croly, and Dr. McArdle.—Specimens exhibited by card by the President, Mr. P. Hayes, Mr. Stokes, and Mr. Croly. Papers: The President, Pharyngotomy.—Mr. Kendall Franks, On Removal of the Tongue by the Galvanic Caustery.—Dr. McArdle, Notes on Stricture of the Rectum.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At 8 p.m., Mr. Hendley, in conjunction with Mr. Benham, On a Case of Poisoning by Ammoniate and Red Oxide of Mercury.—Mr. Howard Marsh, On Three Cases of Osteotomy with Interesting Complications.—Dr. Thudichum, On Two Fatal Cases of Peritonitis simulating Poisoning. He will also exhibit microscopic specimens of Micrococcæ.—Mr. Bruce Clarke, On a Case of Radical Cure of Hernia.—Dr. Thudichum, On several Cases of Ammonuria, and of Exostosis in the Nasal Cavity, with Operation and Treatment.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Flower, On the Principal Types of the Human Species.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The first of the Gulstonian Lectures.—Dr. Clifford Allbutt, Chapters on Visceral Neuroses.

ROYAL INSTITUTION.—At 8 p.m., Mr. C. V. Boys, On Bicycles and Tricycles.

SATURDAY, MARCH 8TH.

ROYAL INSTITUTION.—At 3 p.m., Captain Abney, On Photographic Action.

Vacancies.

Carrickmacross Union, Donaghmoynne Dispensary.—Medical Officer. Salary, £115. Election, March 12.

Coombe Hospital, Dublin.—Assistant to Master. Applications to Master, or at Coombe Hospital.

Kent Hospital.—Physician on the Staff. Applications to the Secretary at the Hospital, Canterbury, by March 24.

St. George-in-the-East Parish.—District Medical Officer. Salary, £250. Applications to the Clerk on printed forms, by March 8.

Sussex County Hospital, Brighton.—Assistant Surgeon (honorary) and House Surgeon. Salary, £80, and £10 per annum for each resident pupil. Also an Assistant House Surgeon. Salary, £40, with board, &c. All applications to be sent to the Secretary at the Hospital, by March 19.

West Kent General Hospital, Maidstone.—House Surgeon. Salary, £120, with furnished apartments, &c. Applications to the Secretary, by March 6.

Worford House Hospital for the Insane.—Resident Medical Superintendent. Salary, £500, with board, &c. Applications to the President, Committee of Management, by March 11.

Appointments.

DALY, C. H., L.R.C.Q.C.P.I., L.R.C.S.I., Medical Officer for the Hoxley District of the Huddersfield Union.

GAYTON, W., M.D. Brux., M.R.C.P. Ed., M.R.C.S., Medical Officer for the North-Western District, under the Metropolitan Asylums Board.

GOOD, F. T., M.R.C.S., Medical Officer for the Second District of St. Neots Union.

GREEN, E. C., M.R.C.S., L.R.C.P., House Surgeon to the Derbyshire General Infirmary.

HOBSDON, J. W. B., M.R.C.P.E. (exam.), an Extra Physician to the Edinburgh Royal Hospital for Sick Children, vice Dr. J. Playfair, appointed Ordinary Physician.

MACDONALD, A., M.D., F.R.C.P. Ed., F.R.C.S. Ed., Physician to the Royal Maternity and Simpson Memorial Hospital.

MACDONALD, W. F., M.B., C.M. Ed., House-Surgeon to the Royal Maternity and Simpson Memorial Hospital.

ORMOND, H. G., M.B. Ed., C.M., M.R.C.P.E., Visiting Medical Officer to Watts' Hospital, Leith.

SANKEY, H. R. O., M.B. Lond., Medical Superintendent to the Warwick County Lunatic Asylum, Hatton.

SMITH, J. W., M.D., C.M. Ed., Medical Officer for the Ryton District of the Gateshead Union.

SPENCE, W., M.B., C.M. Ed., House Surgeon to the Royal Maternity and Simpson Memorial Hospital.

Births.

GASKELL.—February 28, at Grantham, near Cambridge, the wife of Walter H. Gaskell, M.D., of a daughter.

KNIGHT.—February 28, at 82 Harcourt Street, Dublin, the wife of Chas. Frederick Knight, M.D., Highfield Manor, Rathfarnham, co. Dublin, of a son.

Marriages.

ALLEN—TIPPLE.—February 28, at Central Hill Chapel, Upper Norwood, John Davis Allen, M.D., M.A. Edin., of Wotton, Gloucester, to Gertrude Anne, eldest daughter of the Rev. S. A. Tipple, of Norwood.

FRASER—KENNETT.—February 25, at the Pro-Cathedral, Kensington, Dr. John Fraser, of Tintin, North China, to Mary Evangeline, youngest daughter of the late Edward Kennett, of S. Kensington.

Deaths.

FERNIE.—February 22, at Barnstable, Devon, Andrew Fernie, M.D.

JONES.—February 21, at 6 Prince Edwin Street, Liverpool, William Goodall Jones, M.D.

MCCROBERT.—February 18, at Westray, Orkney, Henry Gray McCrobert, M.B. Aberd., & C.M.

PARRY.—February 24, at Farnside, Old Swan, near Liverpool, David Lewis Parry, L.R.C.P. & L.R.C.S. Ed., aged 88.

THORP.—February 28, at 8 Warrender Park Terrace, Edinburgh, Amelia Catherine, wife of Surgeon-Major E. C. Thorp, M.D., Bombay Medical Department.

WOOD.—February 26, at 12 Strathern Place, Edinburgh, Alexander Wood, M.D., F.R.C.P.E., Member of the General Medical Council 1857-78.

The Gulstonian Lectures

FOR 1884.

Delivered at the Royal College of Physicians, London,
March 7th, 12th, and 14th.

By T. CLIFFORD ALLBUTT, M.D. Cantab., F.R.C.P. Lond.,
F.R.S.,

Senior Physician to the Leeds General Infirmary; Consulting Physician
to the Leeds Hospital for Women and to the Fever Hospital.

LECTURE I.—CHAPTERS ON VISCERAL NEUROSES.

GENTLEMEN,—When the revered chief of this College bade me to the high place which I now hold, I would fain have been released from so great a call. It seemed to me that the leisure in which I should search out and think things worthy of so distinguished an assembly had long been denied to me. But I was assured that, although lectures containing the results of systematic research are of the highest importance, there is a place, nevertheless, for lectures conveying the humbler reflections of working physicians who deal with the daily experience of the sick-room and the consulting-chamber. It remained for me, therefore, to obey, and to deal with some part of the field of practice. Herein I have chosen for my subject those painful disorders which have their seat in the nerves of the viscera, but I have entitled my lectures The Neuroses of the Viscera in order that I should be free to enlarge occasionally upon some perturbations of those nerves which are not attended with pain, strictly so called. At the same time, it is with such neuroses as are manifested in pain that I intend more especially to deal. It seems to me that, in our text-books, these affections receive something less than the full treatment which their difficulty and their importance demand, and I find, in general practice, that the part played by the nervous system in visceral disorders is insufficiently seen. To the knowledge and skill of physicians so highly placed as yourselves I cannot hope to add anything, but I would rather seek, through you, and with your aid, to spread abroad a more adequate interpretation of the disorders in question, say-

ing to you, in the words of the Apostle, "Οὐκ ἔγραψα ὑμῖν διὰ τοῦτο οὐκ ἵδαστε τὴν ἀλήθειαν ἀλλ' διὰ τοῦτο ἵδαστε αὐτὴν."

It certainly happens that neuroses above the belt are far more clearly understood than those below. This preference is due in part to the renewed impulse given to the study of thoracic disease by the discoveries of Laennec, partly to the more vivid functions of these parts, functions which excite our admiration and interest in greater measure than the brooding and silent life of the organs of vegetative existence. Of the neuroses, then, of the upper chambers of the body, of migraine, of asthma, of angina pectoris and the like, I shall find but little to say; my attention will be confined almost entirely to the pains and storms of the abdominal regions—to gastralgia, nephralgia, hepatalgia, and their allies. Of the neuroses of the pelvic viscera much has been said. Indeed, if thoracic neuroses have been discussed at their actual value, if those of the abdomen have received less than their due meed of attention, surely those of the pelvis have received an attention, if not beyond their importance, at any rate of far too exclusive a bearing. What I say of these last will be little in description, but more in the way of interpretation.

The first strong impression which I received from the facts of the class with which we now concern ourselves was obtained from the index of my case-books. It has been always my custom to index therein the names not only of my patients, but also of their maladies. I have to each volume two indices, one of names, one of diagnoses.

As each year I have prepared the spaces for these tables, I have been struck with the small space occupied by the malady "dyspepsia." Surely, I thought, if there be one malady which above all others should need a large space, it must be dyspepsia. Yet, year by year, as at the end of them I cast my eye over the tables, was I astonished to find my cases entered as "dyspepsia" to be a mere handful. How could this be? I asked myself repeatedly. "Martyrs to dyspepsia" are to be found at every street-corner, and are said to form something little less than the staple of those who drift from consultant to consultant. Moreover, I had some suspicion that I was in repute as a stomach-doctor, and was, at least, conscious of a readiness to receive such cases, and to work patiently

with them. I thought, also, of that long-suffering organ itself, and its work—of the greediness or recklessness which make it the helpless receptacle of all sorts of rubbish; I pictured to myself the contents of the viscous distended with greasy, acidulous or trashy matters, sodden in half-fermented gooseberry-juice or sour claret; and I stood amazed that it resists destruction. Yet not only does it survive, but it patiently draws order out of disorder, sweetness out of foulness. Again, as I turned to the journals of the day, I read of men of lofty endowments, whose lives became accursed by dyspepsia; and on other sheets I read many columns of advertised solace, from wind-pills to the pill of the American doctor, whose virtues were thus rendered at Cambridge:

"Hæc jecur instigat, stimulus hæc renibus addit,
Ambulat arcana hæc faciturna via.
Attamen hæc eadem latebras penetrabilibus imas
Mordacis buxi more, modoque petit."

Our medical journals all tell us the same story. Every large drug-house has its pepsines, its dinner-pills, its cordial bitters, testifying not only to the general, but to the medical, cry for help against the demon of dyspepsia. Finally, so confident is the public of the true form of its enemy, that one of this sort who seeks the doctor will dictate his diagnosis, declaring himself an old dyspeptic, and demanding your specific. A hundred doctors have pronounced him dyspeptic; needlessly, for who can know it better than himself! He will condescend, perhaps, to admit some discussion of the respective vices of his stomach and of his liver, but he is offended if you seek further. He half tells you that, if you have yet to learn what is meant by a dyspeptic or by "biliousness," you are no man for him. Patients have positively left me in dudgeon because I ventured to hint that the word indigestion expresses rather an inference than a fact, and pointed out that diagnosis belongs to the physician, and not to the client.

How is it, then? How are we to explain this catholic wailing over a disease which is not; this wealth of balsams for sufferings which cannot be named? Is there no distress to lull, no pain to lenify? In turning our minds to this question, let us, in the first instance, consider the meaning of the word dyspepsia, and ask ourselves if there be in it any such confusion as may account for its indefinite uses, and whether in such uses there be equivocations such as to account for the doubts to which I have referred. I believe that, if I thus follow the origin and paths of my own thoughts in the past, I shall best open out the main subject of my address. Forgive me if I thus approach the subject of visceral neurosis by an indirect method, and in the way of comment upon the affections of the stomach. It is almost trivial to remark that dyspepsia, strictly speaking, is not a disease, but a symptom; it names not the causes nor the process of the evil, but its consequences; that, as an outcome of the affair, whatever it may be, food is not digested, or is digested imperfectly or painfully. Taken in this sense, no doubt dyspepsia is an exceedingly common complaint. But if the word be used in this sense, does not its meaning become almost futile? As a consequence of various conditions, let us say, persons may find themselves unable to walk far, to walk steadily, to walk painlessly, or even to walk at all. Yet are we to use a word such as dyskinesia, and to say that whosoever comes to us walking ill, whether from general debility, from palsy, from sciatica, from muscular rheumatism, from gout, from disease of foot, ankle or knee, that he is suffering from dyskinesia? Are we to say, of a patient whose forces are so diminished that he can walk only a mile, and this with fatigue, that he is suffering from atonic dyskinesia? Are we to treat all the above maladies in a chapter under the heading of dyskinesia, and in a few columns of entanglement try to deal intelligibly with such a subject in such a way? We should not be saved from the discredit of foolishness if we were to do so. Then how are those to be spared who, using the word dyspepsia in this way, devote chapters and books of chapters to such a symptom and raise that

which is accidental and consequent to the place and name of a definite malady? Yet I have only to turn to any modern text-book to find page after page of such writing, pages to which I would willingly refer accurately were it not that I would avoid even the seeming of personal controversy with authors whose industry and thoughtfulness have done so great a work for modern medicine. If, however, we would speak wisely and strictly, shall we not seek to clear away this kind of confusion, and set out in their natural groups as distinctly as we can the several classes of symptoms now heaped together unreasonably? Thus we shall better understand the cases which come before us, and taking a larger view of them, see better how to cure them. Perhaps, too, by this method, we shall even do away entirely with the word dyspepsia as the name of a malady, and reduce it to the position, for instance, of the word cough, which has no definite connotations, and signifies only an inconvenient and notorious symptom common to many maladies.

Sifting, then, as we must, the heap of affections attended with dyspepsia, we readily enough propose four chief groups of stomach-disorders. First, those which are due to grave disease of the stomach itself, such as cancer or ulcer of the organ, dilatations of it, atrophy of its coats, and so forth. Secondly, to diseases of the stomach less grave but still local, such as the simpler catarrhs, acute and chronic gastritis. Thirdly, disorders which depend upon no visible changes in the structure of the stomach, but consist in some disorder of its work or secretions, and which, in accordance with a convenient use of words, we call functional; the dyspepsia of gout may perhaps be taken as an instance of this group. Fourthly, disorders which depend, not upon any primary derangement of the tissues of the stomach, but upon some influence coming from blood or nerve, from which influence visible local changes may or may not ensue. We put aside the first class of cases, without difficulty, as quite foreign to our purpose; and, so far as they can be distinguished, we put aside the second class also. This it is easy to do in the instance, say, of chronic or acute gastritis caused by the excessive use of alcohol, or, again, in the instance of that common and transient catarrh of the stomach attended with loss of appetite, headache, coated tongue, constipation, sickness, and malaise, which is due often to cold, often to improper feeding. This affection accounts for a large number of the cases called bilious attacks, though the majority so called are probably migraine. It is easy to make some such progress as this, but, thenceforth it is not easy to plan out our schedules further. We may leap over a score of doubtful cases, and passing at once to another extreme, separate into a class all cases which are obviously neuralgic; but between these positions lie a great number of cases which are hard to classify. Is pyrosis, for instance, some local affection of the coats of the stomach, or is it a neurosis? Is flatulence, are all acid risings in the stomach due to some irregular transmutation of the contents of the organ, or are some of them consistent with the course of normal, if feeble digestion? In the former case such derangements may fairly be called dyspepsia, for the process of digestion goes wrong, not as a detail or subordinate part of larger or systemic irregularities, but as a simple and local error in the digestive work of the stomach itself. In a word, is stomach-derangement, in a given case, but an expression of some general derangement, or is it a substantial ailment, and the cause rather than the consequence of any more general perturbations. Even this may be very difficult to estimate, or it may be decided only on the study of individual cases, but a large number of cases remain which are yet even harder to interpret, cases in which dyspeptic symptoms are no doubt due to disordered work or secretion in the stomach, but in which this disorder of work or secretion may, in its turn, be due, not to any primary defect in that organ, but to some cause lying outside of its peculiar tissues, lying, for instance, in the blood or in the nervous system.

Omitting, as I must do, all reference to blood changes, let us take as an extreme instance a sudden nervous shock, which may arrest digestion completely, and we may thereafter conceive of lesser degrees of nervous perturbation which may bring up a continued interference with digestion, or, in other words, cause a continual dyspepsia. We may conceive indeed that not only in this way digestion may simply be slowed, but also the peptic secretions or processes be positively vitiated, as is the case, say, in neurotic diarrhoea.

Or, to turn to a different point of view, a patient who suffers from many symptoms indicative of nervous derangement tells you that on the empty stomach—generally in the morning, before breakfast—a dense yellow oily fluid gathers, and, lying there all day, would vitiate the viscous, would act as an eccentric cause of headache, and as a foul ferment upon the food in the course of digestion; so that his or her only hope of a comfortable day is to vomit or wash out these dregs at the beginning. Now, such an exudation may be due to some chronic distemper of the coats or glands of the stomach; but I incline to believe it is due rather to some perturbed innervation of a stomach otherwise healthy, seeing that the symptom is one which I have always found in neurotics, and to be curable only by treatment planned mainly upon this diagnosis. Disordered work and distempered secretions, then, may well be due to, and doubtless often are due to, neuroses of the stomach; and such neuroses, lying between the more localised disorders and the purer neuralgias, are difficult to classify. There is one more difficulty, though in practice a less embarrassing one; namely, that, as distempered secretion may be the effect of disordered nerve, so, reversely, some slighter catarrh, or other local change, or some offending article of diet; or again some graver local mischief, may, as peripheral irritants, set up nerve-disturbances which in certain susceptible persons may so wax as to over-shadow or conceal the primary cause of their occurrence. We know, for instance, that the touch of a bronchial attack, or of an acute pneumonia, may first reveal an asthma till that moment wholly latent—latent, it may be, till middle or even later life, or latent, it might have been, for ever. But the sleeping ill, once awakened, rarely recedes again altogether, but, by its own recurrence, tends to rivet upon the sufferer the chains of habit. Thus, it may become difficult to say which is the predominant factor in the consequent group of discomforts. As a practical difficulty, this is most serious in cases in which ulcer may or may not be present; and I do not hesitate to say, gentlemen, even before you, that in some of these the diagnosis between ulcer and pure gastralgia is, in certain stages, impossible. How are we, then to succeed as ministers to the sick, if we crowd into one chapter, and almost into one point of view, the pure neuralgias of the stomach, the neuralgias awakened by local irritations within the viscous, disordered secretions or metabolisms within it due to perturbed innervation, together with primary dyspepsias of local origin which concern the nervous system but little or not at all? Never can we succeed, I think, if we make such a confusion. We must endeavour, then, not only to separate the pure neuralgias from the dyspepsias or pains of local origin; but, however difficult it may be in any one instance, we must endeavour farther to decide, concerning mixed cases, whether the neuralgic phenomena stand in causal relation to the local disorders of function, or, contrariwise, the disorders of local function have awakened nervous reverberations. That which reason and examination may fail to discern may often be revealed to us by the test of treatment. The relation of asthma to disorders of the lungs has been quoted as an illustration of these difficulties. In some cases, then, we have to deal with a pure neurosis of central origin; in others, with nervous phenomena awakened by persisting or foregoing local maladies; and, unless we see with some clearness how these phenomena are related to each other, we shall fall short of a rational therapy.

In order to enter by the plainest route into the more

intimate knowledge of neuroses of the stomach, let us advance from the simplest to the more complex. No cases, perhaps, will serve us better as an introduction than those in which disorders of digestion occur as a consequence of general nervous exhaustion. Unlike gastralgia, these disorders may arise in men and women of very various habit of body. No general sketch of the bodily aspect nor of the temperament of such patients can be delineated, and accordingly we find the symptoms various.

Omitting, then, persons disposed to gastralgia, we find two kinds of dyspepsia at least arising in persons overworked. In the first class, we find simply a feeble stomach, as we find enfeebled legs and an enfeebled brain. The tongue is clean—too clean; not red, but pallid. Its substance is oedematous, and its edges indented. Such a person has no appetite, and the little he eats causes a weary sense of repletion, until the ingesta slowly pass off. We may call this dyspepsia, as we may call the leg-weakness, dyskinesia, and so forth; but the whole man is run down—call it general dysergy, if a fine name must be found. But now take another man, equally without marked diathesis, and equally overworked; his tongue is bulky and also indented, and is protruded slowly, spreading forth as it issues. It is thickly coated, especially towards the mid-line, where the fur is brownish, and brownish towards the back also. The complexion is muddy, and the countenance bears the mark of mental depression. The hand is placed fretfully upon the vertex, where there is a pain, or, if not a pain, a peculiar indescribable uneasiness; and this passes backward, surrounding the occiput. The urine deposits lithates, and the liver and stomach not only work feebly, but their functions are aberrant. He is weary and dull, and says he feels like a dead dog of a morning. A like state of tongue, and a like sluggishness and diversion of stomach, liver, and colon, may be seen in most cases of common apoplexy, and are clearly secondary to the troubling of the brain, though the converse view is usually held, and the attack of apoplexy attributed to a foregoing upset of the digestion. Why, of the two overworked men, nervous exhaustion should produce in one a simple atony of the stomach, and in the other an aberrancy, I cannot say. I suspect the latter man has in himself some echo of gout, but yet I know how disappointing are all attempts to clean his tongue and set his stomach aright with the stock rhubarb and soda mixtures, with pepsines, with calomel, colocynth, or colchicum, and how that even strong tonics, such as quinine and iron, may be prescribed with benefit, and how rest and upland air will beat all medicines whatever, and may clean the tongue in a fortnight. Dyspepsia here is a symptom, and the stomach is disordered; but radically the state is a neurosis, vascular or other, and curable only upon this understanding.

(To be continued.)

At a recent meeting of the Suffolk (U.S.A.) District Medical Society, Dr. Gay exhibited a black-headed steel bonnet-pin, six inches long, removed from the urethra of a man seventy-five years old, who, "having nothing else to do," had introduced it head foremost, and had let it slip through his fingers.

THE University of Oxford, by a decree of Convocation passed on March 4th, has authorised the Professor of Anatomy and Physiology to engage a table for the use of students of the University at the zoological station of Villefranche. Some demonstration against the proposal was indulged in by anti-vivisectionists, but they abstained from going to a division on the question.

Lectures ON THE EYE: ITS DISEASES, AND THEIR REMEDIES.

*Being an Abstract of a Course delivered in the Royal
College of Surgeons in Ireland,*

By ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
Professor of Ophthalmic and Aural Surgery in the College;
Ophthalmic Surgeon to the House of Industry Hospitals.

(Continued from page 157).

LESIONS of the cornea are of three classes, and may be grouped as follows:—

- a. Inflammations (corneitis-keratitis)—
 1. Diffuse, interstitial or parenchymatous keratitis.
 2. Punctated keratitis, once called aqoucapulitis.
- b. Ulcerative conditions—
 1. Herpes cornealis.
 2. Abscess or onyx.
 3. Simple ulceration.
- c. Vascular hypertrophy—
 1. Pannus.
- d. Sequelæ—
 1. Opacity or staphyloma (keratoconus).
 2. Conicity of cornea.
 3. Arcus senilis.

Those diseases which I have classified above as inflammations are always of constitutional origin, and occur as symptoms of a taint, whether strumous or syphilitic, and their onset is marked by decided pathognomonic conditions.

Keratitis diffusa is an invasion of the structure of the cornea proper by a proliferation of the corneal corpuscles which swell up, branch out, multiply, and expand the interlacing canals by which the cells communicate, causing the structure to assume the condition of a network of anastomosing tubes. At the same time the lymph contents of the cells become opaque and slightly granular, and thus the transparency of the cornea is lost.

The disease almost always commences in one eye, and runs its course before it develops in the second eye, and it is excessively slow, both in its development and its resolution, so much so that when the onset of a diffuse keratitis is diagnosed, it may be predicted that three months at least will elapse before both eyes have gone through the attack. The inflammatory opacity which is at first limited to a patch of cornea extends by degrees until the entire structure is engaged, at which stage the glossiness of the corneal surface is completely lost, and it assumes an appearance of evenly disposed granular dimness, exactly resembling coarse muffed glass. After a time if the inflammation be intense normal blood vessels become developed at the corneal margin, and may be seen extending inwards towards its centre, and giving to the opacity more or less of a patchy red colour. The most manifest concurrent symptom is intolerance of light and lachrymation, which conditions are often very troublesome, but there is generally not much aching pain either in temple or eyeball. Throughout the course of the disease the ciliary region suffers much congestion, as is manifest by a well-defined pinkness of the sclerotic, especially at the circum-corneal zone, and this colour being uncomplicated by any conjunctival vascularity is very indicative of this disease.

Diffuse keratitis rarely results in suppuration or ulceration, and it is not accompanied with swelling of the lids or conjunctival engorgement. When suppuration does take place these complications, together with some aching pain, are added to the other symptoms. In ordinary cases the disease increases in severity for about ten days, remains stationary for about a fortnight, and occupies about a month or six weeks in resolution, during which period the second eye is usually attacked; but there

are the widest variations in these periods. When all inflammatory symptoms have passed away a faint diffused opacity remains which takes months to clear off; eventually transparency is almost completely restored, but, generally speaking, the cornea will have suffered in shape from the disintegration which it has passed through. Conicity of the cornea, which I shall refer to as one of the sequelæ of corneal disease, remains a permanent blemish.

Causes.—I have said that keratitis is almost always associated with a constitutional cachexia. Formerly this taint was always identified with the strumous diathesis, and the disease was known as "chronic scrofulous corneitis," but in the year 1863 Mr. Jonathan Hutchinson identified the disease as being, in many cases, associated with hereditary syphilis. Being a symptom of constitutional disease this keratitis shows itself at the period of life at which diseases of strumous and syphilitic origin usually manifest themselves, i.e., between childhood and 17 years of age. Mr. Hutchinson observed that it was commonly to be seen in children who had the syphilitic physiognomy, and who had a history of disease of the nasal bones, skin eruptions, &c., and he noted as a specially diagnostic symptom the stunted development,

Fig. 17. Syphilitic Teeth.

and a peculiar notching of the teeth, of which I give an illustration, and which he describes as follows:—

"Coarse, flabby skin; pits and scars on the face and forehead; cicatrices of old fissures at the angles of the mouth; a sunken bridge to the nose, and a set of permanent teeth peculiar for their smallness, bad colour, and vertically notched edges of the central upper incisors, coincident with, or preceding the keratitis, may be found; ulcerative lupus; nodes on the long bones; psoriasis of face; otorrhoea; chronic enlargement of tonsils; throat ulcers; thickening of the parts under the tongue; and chronic engorgements of the lymphatics."

Fig. 18. Syphilitic Teeth (HUTCHINSON).

"When first cut," says Mr. Hutchinson, "these teeth are usually short and narrow from side to side at their edges. In the edge is a crescentic portion thinner than the rest, which, after a time, breaks away, leaving a broad, shallow, vertical notch."

My own experience is that keratitis is a disease of cachexia, but not necessarily of the syphilitic dyscrasia, and that a strongly tonic line of treatment is always essential whether mercurials be given or not.

Keratitis punctata is another form of disease closely related to constitutional cachexia. It is extremely slow in its course, even more so than the parenchymatous keratitis, and its peculiarity is in the deposit between the corneal layers of minute greyish yellow deposits which give the cornea the appearance of being spattered on the back with a paint brush, hence the disease is called punctated corneitis. These deposits are usually situated between the posterior layers and on the free surface of the posterior lamina, hence it was formerly considered to

be a disease of the membrane of the aqueous humor, and was called aquo-capulitis. It is very frequently associated with chronic irido-choroiditis or other slow inflammations of the deep seated structures of the eye, and as there is generally some dulness of the cornea, besides that due to the punctiform deposits, and some haziness of the aqueous humor, there is a good deal of loss of light.

The treatment of both the parenchymatous and the punctated forms of keratitis should be directed to the strengthening of the patient in every way possible. If there be other distinct evidences of syphilitic taint, and if the disease be acute, mercury by inunction may also be necessary, and, even in doubtful cases, I am accustomed to give a little grey powder or other mild mercurial alternative, and the bichloride of mercury in doses of one-twelfth of a grain combined with tincture of bark is also very useful when the disease is not acute. For the weakened cachectic condition of the patient, open air and abundant nutritious and digestible dietary are essential, and with them cod-liver oil, iodide of iron, quinine and iodide of potassium are very useful.

In the local treatment I have found it beneficial to maintain an open blister on the temple, to instil atropine solution three times a day as a sedative to the inflamed surface, and to keep the eye quiet with a compress and bandage. Irritants or stimulants to the eye surface are altogether objectionable, while hot poppy stupes and steam are not only grateful to the patient, but of curative value. The prognosis is always good, and the recovery generally complete, but the patient should be warned of the excessively slow course of the disease, and of the possibility of permanent aberrations of sight, arising from the alterations in curvature of the cornea; of these I will speak when dealing with "conical cornea."

Is so clearly related to the herpetic or phlyctenular form of conjunctivitis that it might be regarded as only an extension of the latter disease. It begins with a minute circumscribed swelling or pimple within the substance of the cornea, which causes great pain and intolerance of light, and is likely eventually either to burst on the surface or establish a corneal abscess, ending in a deep ulcer of the cornea and subsequent cicatrix, or in an opening into the anterior chamber with deposit of pus therein. This nodule usually presents, at first, a watery vesicle at its surface, and is surrounded with an areola of grey cloudy lymph thrown out within the corneal structure; and when the point of the nodule has ulcerated the ulceration is liable to extend within this areola. These herpetic nodules are usually close to the corneal margin, and in company with conjunctival phlyctens, and a large bunch of red vessels will be seen leading to them from the conjunctival surface, and forming a triangle which has its apex at the phlycten. At the same time there is great intolerance of light, abundant lacrymation and spasm of the lid, and a greater degree of aching pain than occurs in simple conjunctival herpes. The extent of these symptoms, and the amount of danger to the eye are measured by the number and depth of the phlyctens, which may be quite superficial and numerous, in which case they readily heal up, or they may be solitary and deep, in which case dangerous ulceration commonly results.

The exciting cause of these attacks and of the frequent relapses which are a characteristic of the disease is to be found in a low condition of health, and that particular nerve condition which produces herpes zoster or any of the allied affections. It is also frequent as a sequela of measles and the other exanthemata, and in weakly children of scrofulous temperament. It is on many occasions part of a general impetigo which breaks out on the face and head, especially at the roots and back of the ears, corners of the nose and mouth, and on the cheek, and the pain and inconvenience of the eye disease is then greatly aggravated by the itching, burning, and tenderness of the herpetic surface; hence the physiognomy of these cases cannot be mistaken.

Treatment.—The constitutional treatment of corneal

herpes is in great measure the same as that of phlyctenular conjunctivitis, to my description of which I refer the reader. As I have said in reference to phlyctenular conjunctivitis, the constitutional treatment of these cases is of supreme importance. Fresh air, nutritious dietary, change of air when possible, regulation to the gastro-intestinal system, and the most rapid effective tonics are indicated. The patient, if a child, should sleep by itself in a cot without curtains, the room being abundantly ventilated and not too dark. Beef-tea strong and frequent, milk with lime water, custard puddings with eggs, in fact, the most nutritive and digestible dietary possible is necessary. The patient should walk, drive, or be carried out of doors two or three times daily, not smothered in coverings, or with a handkerchief held to the face. As regards internal treatment a stomachic and alternative of grey powder with ginger should be given at night, and the bowels cleared with castor oil if necessary.

But as there is in the corneal disease a serious danger of abscess and ulceration, and perforation, which does not present itself in *herpes conjunctivalis*, the local treatment must be modified. In the superficial little herpetic blisters a simple sedative line of treatment with instillation of atropine and with sedative evaporating lotions will suffice, but where the herpetic nodule is deep in the cornea the most active means ought to be adopted to allay the inflammation, prevent lymph infiltration of the cornea, and, if suppuration be inevitable, to bring it to the surface, and not permit it to perforate the anterior chamber, in which case the eye must suffer serious permanent injury. When suppuration of a pustule is threatened sulphide of calcium, which is to be had in doses of 1-30th of a grain made up in coated pilules, is highly recommended as a resolvent, and one pilule may be given thrice daily. If suppuration has commenced hot poppy stupes and poultices should be applied, and where the surface has ulcerated a bandage and compress may be necessary, but the sooner the condition of ulcer will permit of these being dispensed with the better for the patient. In this view I differ in opinion from many authors, who regard compresses and bandages as indispensable in all stages of the disease. Cod-liver oil, iodide of iron, and, in adults, a combination of arsenic, quinine, and iron are very useful. When the inflammation has passed off, the dusting of the ulcer with calomel and the use of Pagensticker's ointment helps complete the cure. The instillation of atropine is useful, not only for its sedative effect upon the ulcer and the ciliary system, but because it tends to reduce pressure within the eyeball, which, when the cornea is thinned and softened, irritant applications of any sort are to be forbidden, and except in the last stages of the disease, where it may be necessary to stimulate the healing of an indolent ulcer.

The concurrent herpetic eruption of the chest, nose, mouth, and ears will also need local emollient treatment, which consists in frequent bathing with lukewarm milk and water or tepid solutions of chlorinated soda, removing the scabs wherever they are exfoliating, dusting with violet powder the raw surfaces, and, in the intervals, keeping the surface greased with dilute oxide of zinc ointment, vaseline, or glycerine cream.

After recovery from an attack it is of high importance to continue the constitutional treatment to prevent relapses, a precaution which is frequently neglected. Iodide of iron is specially indicated at this time, and, if the season permit, sea bathing is all powerful to prevent recurrences.

(To be continued.)

THERE are forty lady students at the Paris Faculty of Medicine of different nationalities. The French are greatly in the minority, and the Russians head the list.

A NEW FORM OF EYE DROP-BOTTLE.

By H. MACNAUGHTON JONES, M.D., M.Ch.,
F.R.C.S.I. & E.,

Formerly Surgeon to the Cork Ophthalmic, Aural, and Throat Hospital,
Professor in the Queen's University, Ireland.

THE essential qualities in a good eye drop-bottle are—
1. Convenient size ; 2. Ready, but not too rapid, dropping of the fluid ; 3. Exclusion of the air and protection of the liquid from dust particles when the bottle is not in use ; 4. Protection from the influence of light. Liebreich's well-known drop-bottle, which I have used for several years past, has certain drawbacks and disadvantages. I have found these in practice to be—*a*. Uncertainty of flow ; *b*. The cork, when the bottle has been a little time in use, becoming loose, and the glass tube also loosening in the cork ; *c*. Exposure of the solution to the action of sunlight ; *d*. Entrance of dust particles. To have a bottle in which these defects would be obviated appeared to me a great want. Accordingly I have had made for me a bottle by Messrs. Maw & Son, as depicted in the drawing.

These bottles are made in two colours, blue and yellow. The stopper is made of rubber and vulcanite, and fits accurately and tightly the neck. The vulcanite portion is all in one piece, and forms in the centre the narrow tube for the exit of the fluid. This stopper is covered by a neatly-fitting air-tight cap. The entire bottle, of the exact size shown in the drawing, is very light, and, as in the bottle of Liebreich, by simply holding it in the hand and inverting it, the drops are expelled. There is no waste. For the use of eserine (so prone to decomposition) duoboisine, pilocarpine, gelsemine, and atropine, or nitrate of silver, by preventing the entrance of dust or the rapid generation of fungi, and arresting the action of light on the alkaloid, this bottle will be found of great use. There is an obvious advantage to the surgeon and patient in the different coloured glasses, which distinguishes at a glance, and without label, the nature of the contained solution. It is comparatively inexpensive. While on the subject of the alkaloids, I may, in passing, draw the attention of practitioners to the superiority of the salicylate salt of eserine (made for me by Messrs. Corbyn, Stacey & Co.). It is more stable than either the hydrobromate or sulphate, though it is not so widely known and used.

141 Harley Street, W.

Mr. W. P. MEARS, author of the well-known student's "Text-book of Schematic Anatomy," has been elected Examiner in Anatomy in the University of Durham.

Clinical Records.

SHEFFIELD GENERAL INFIRMARY.

Case of Bell's Paralysis followed by Contraction of Facial Muscles.

Under the care of Dr. H. FRENCH BANHAM.

JANE H., *æt* 29, was admitted into the Sheffield General Infirmary in December last. She was married at the age of 19, and has had eight children, two of which are living, two were still-born, and the remaining four died within a few days of birth. Her mother died at the age of fifty-five and her father is still living. She has lost fourteen sisters and one brother, some of whom, it seems probable from her account, died of phthisis. At three years of age she had small-pox, after which she had an inflammatory affection of the left eye, followed by opacity of the cornea, and the sight has remained so far impaired, that she is only able to see the bare outline of large objects. Within two years of her marriage she had a number of sores about the front and sides of her neck, but not elsewhere on her body. She has not suffered from sore throat or eruptions on her skin at any time. About a year ago she had what she called a "stroke," which affected, however, only her face, not any of the extremities. On the evening previous to the attack she went to bed feeling perfectly well. On awaking in the morning she noticed that she could not pronounce some words distinctly, and in the afternoon when her husband returned from his work, having been away from home since half-past five in the morning, he remarked to her that her face was all awry. She found on looking in the glass that the right corner of the mouth was drawn up, and shortly after she was unable to close the left eye. Her hearing, so far as I can ascertain, was not affected, but to some extent she had lost her taste. Within a few weeks her face seemed to regain its normal appearance, and she supposed she was recovering, but, subsequently, a slight progressive deformity seems to have developed on the left side of the face.

At the present time, the left side of the patient's face seems to bear a cynical smile, the left nasal fold is more distinct than the right, and the left angle of the mouth is slightly drawn up, slight twitching movements are occasionally noticed about the left side of the face, in conversation and on being requested to make certain movements. The left cheek is rather firmly applied to the jaws, and when the finger is introduced into the mouth between the teeth and cheek, she experiences pain and the fibres of the buccinator are felt to be tense and cordlike. The mucous lining of the cheek is jagged and puckered, owing to it having been rather severely bitten during mastication. The uvula is distorted and scarcely any movement is performed by the soft palate in making the sound "ah". The left eye cannot be examined on account of the opacity of the cornea. The right eye is healthy. Her hearing on both sides is good.

There can, I think, be no doubt that this patient suffered a year ago, from an attack of neuritis affecting the facial nerve, not merely of the part external to the Fallopian canal, but also of that internal to it, and, indeed, extending up to the geniculate ganglion. Whether the neuritis was of the ordinary rheumatic form, as is so commonly the case in Bell's paralysis, or of a syphilitic nature, I cannot at present determine. It has, however, been attended by such an amount of exudation, of probably a plastic character, as has led to some degeneration taking place in the muscles supplied by the branches of the facial nerve. Neuritis affecting that part of the facial nerve which is external to the Fallopian tube, is not so likely to produce a destructive compression of the nerve and consequent degeneration and contracture of muscle, as is the same amount of inflammation taking place within the unyielding bony canal. The present condition of the uvula and soft palate, coupled with the fact of the defect of taste, which she experienced at the onset of the attack, indicate very clearly, also the involvement of the deep portion of the nerve. I would call attention to the fact that the muscles are not spasmodically contracted, but that they have undergone organic contracture. Spasmodic contractions may be overcome by firm pressure and without causing pain, but a muscle which has undergone contracture cannot be extended, and the first attempt gives rise to severe pain.

ACADEMY OF MEDICINE IN IRELAND. SURGICAL SECTION.

Mr. W. I. WHEELER, President, in the chair.

DEBATE ON THE RADICAL CURE OF HERNIA.

Mr. W. THORNTON STOKER said in considering the subject they should hold clearly in mind that there were two distinct classes of cases in which they operated and hoped to have a radical cure—one the class in which they were compelled to operate by the existence of strangulation and the other where the operation was purely a matter of election to promote the convenience of the patient rather than save his life. As the result of his experience in the majority of cases where he undertook an operation for strangulation a radical cure had been effected. In nearly all cases of operation for femoral hernia a permanent cure had been effected, even though the surgeon had no design beyond saving the patient from the consequences of the strangulation. But in large inguinal ruptures a radical cure was not so frequent, and in such cases he could not conceive a surgeon omitting to suture the peritoneum. In his first case he performed herniotomy, about twelve years ago, in Baggot Street Hospital, where he operated on a woman for strangulated femoral rupture. Then for the first time surgeons were discussing the propriety of suturing the peritoneum in ovariectomy. It occurred to him that he ought to put stitches in the peritoneum for the same reason as in ovariectomy, and so by closing the peritoneum save the patient from the great danger of peritonitis. Ever since he made it a point to suture the peritoneum. The suture should always be put into the peritoneum in such a direction that the axis of the needle would be parallel to the long axis of the hernial sac. He had been struck with the omission to mention, except in a passing allusion by Mr. Franks, the operation devised by Spanton, and spoken of as the corkscrew operation. The measure of success that Spanton had attained was so great as to prevent the operation being passed over in silence. Indeed, the results had been surprisingly successful and safe. When he read a paper on the subject himself he was an advocate in the second class of cases for Wood's operation, and he was not inclined as yet to renounce his allegiance to it. He saw but little to be gained by making a free dissection of the parts, such as could be done under antiseptic spray. A great argument for performing Wood's operation under spray was that a good view was obtained of the parts under suture. He did not think it mattered much whether the pillars of the ring were drawn together or not. The way a cure was effected in those cases was by causing enough of inflammation to excite the exudation of a large mass of coagulum and lymph, which drew the parts together, and to some extent formed a cork, which closed the opening. Mr. Barton scarcely did justice to Wood's operation, its fatal results being 1 or 2 per cent. Two years ago Wood operated on 200 consecutive cases subcutaneously without a single death; and his results of cure were greater than Mr. Barton had stated, being from 80 to 85 per cent., a large proportion, recollecting that he operated on cases of all sizes and all ages. He entered his protest against the fashion which was obtaining now of leaving in the wire suture in cases where the ring was sutured in inguinal hernia. That was a most unscientific and unsurgeonlike procedure. Although the wire might be safely encysted, a time of trouble might come when it would be a source of trouble. In no case of rupture could the operation be so successful that at a future day the rupture might not come down again; and if the rupture returned and the patient had a coil of wire encysted in his abdominal wall the result was inevitable. If it was his misfortune to have a rupture he would be sorry to let any surgeon leave a wire in his abdominal wall.

The PRESIDENT said, as he had been asked by Mr. Barton to contribute to the debate, he would relate the result of a few cases he had copied from his note-book, regretting that other engagements prevented him from making a full report. In 1876 he operated after Wutzer's method on a large left scrotal hernia. The age of the patient was thirty years. The operation was partially successful. The hernia descended into the canal, but not into the scrotum, and could be kept up by a truss. In the same year he operated on a small inguinal hernia in a male, æt. 35. The course adopted was invagination with pins passed across the canal. The hernia was not im-

proved. He operated on this patient again with good result, the hernia only protruding a little at the internal ring when the patient coughed. The third case in the same year was also one of inguinal hernia in a male on the left side. The neck of the sac was exposed. He then drew it down and applied a ligature and divided the neck and removed the sac below the ligature. This case was successful when seen two years after the operation. In a fourth case he performed a similar operation in a case with Dr. Byrne. The patient, a female, suffered from a small inguinal hernia in the centre and above Poupart's ligament, which became strangulated. She was perfectly cured, and more than five years had elapsed since the operation. A fifth was a case of femoral hernia strangulated on left side in a female, æt. 18. He opened the sac, pulled down, excised, and closed edges. The result up to eighteen months after the operation was most satisfactory. He had lost sight of the patient since, and believed she had gone to America. A sixth case was a large reducible inguinal hernia in a male, æt. 42. He adopted the dissection method. The hernia was not improved. A seventh was a similar case, and the same plan was adopted with a like result. In two cases of inguinal hernia, left side, in children aged respectively 10 and 5 years. The dissection method was adopted in both with the result that the hernia was not improved in the child of ten, while it was very successful in the child of five. In a case of strangulated umbilical hernia which he had recently operated on in presence of Dr. B. McDowell and Dr. Byrne, the wound healed by granulation, and the radical cure was thus effected. That surgeons were not satisfied with any particular operation for the cure of hernia was evidenced by the fact that so many operations had been devised. Some preferred what had been termed the "hidden operation," alluding to Mr. Wood's, and others; while some preferred what had been called the open, or dissecting operation. This operation, although thought to be a new one some little time ago, was, he believed, performed nearly a century ago, as was well described in Mr. Gross's Surgery, and admirably alluded to in the review of that work by Mr. Richardson, and practised by the late Mr. Walsh in the Adelaide Hospital. He thought that the criticisms by the author of the first paper read respecting Mr. Agnew scarcely represented what was intended to be conveyed; for Agnew said of 62 cases treated by Gardy, 4 died, and there were no means of knowing how many were cured. Dr. Weber, who was cognisant of the result, said that of 14 cases operated on by Wutzer, not a single one was cured. Agnew spoke of his own operation with distrust. Wood, of London, had operated 155 times, with 113 cures, 40 failures, and 2 deaths. The duration of the time of cure of the 113 cases was not ascertained. Dr. Dowell, up to 1876, reported 96 operations, with 80 cures and 16 failures. He (Mr. Wheeler) was of opinion that the cases brought forward in the first communication were not operated on sufficiently long to say whether or not a cure would result, and he believed also that in cases where the canal was much widened, greatly distended by a large hernia, it would be almost impossible to have a radical cure follow any radical measure, and the most likely was by excision of the sac.

Dr. McARDLE mentioned that at the Surgical Congress in Berlin, Czerny brought forward six cases of congenital hernia, in which the pillars of the ring were sutured with catgut; and of these, four were successes, while a fifth—a child six years old—had necrosis of the testicle, and the sixth—a boy, æt. 6—had thrombosis of the veins, resulting in death. In joining the pillars of the ring it was almost impossible to bring the edges sufficiently closely together to keep behind the sac. The irritation of the veins was likely to produce phlebitis.

Having regard to the lateness of the hour, the further discussion was—on the motion of Mr. Ormsby, seconded by Dr. McARDLE, adjourned to a special meeting.

THE ADJOURNED DEBATE ON THE RADICAL CURE OF HERNIA

was opened by

Mr. LAMBERT ORMSBY, who had moved the adjournment of the discussion of the communications on the radical cure of hernia, said it devolved upon him to open the debate. He had moved the adjournment at the previous meeting owing to the lateness of the hour and the fact that so many of the members had not had an opportunity of stating their experience in the treatment of an important surgical affection. He had listened with great pleasure to the papers of Mr. Stokes, and Drs. Barton and Franks, and although the procedure of

each surgeon differed, yet all tended to the same end in endeavouring to cure a most troublesome and frequently fatal surgical disease. The radical cure of hernia, as had been said by previous speakers, was a subject that had exercised the minds of surgeons from time immemorial. Procedure after procedure had been suggested, performed in many cases, and then discarded; and many operations carefully described in the present day were nothing more or less—with few exceptions—than old operations revived under a new name. Mr. Stokes' procedure no doubt was a bold and somewhat heroic one. However, in these days of enlightenment, with the aid of antiseptics and a complete regard to the details of Listerism, one might perform operations in abdominal surgery with the greatest impunity as regards the after consequences. Some of the members present might be rather surprised at hearing him make such an assertion, as he had been formerly such a sceptic as to the advantages of complete Listerism in the treatment of wounds. However, for some years his mind had been undergoing a change by extended experience and examination of the subject, and he now thought it was only right to acknowledge his firm belief in the complete details and advantages of Listerism. He had himself attempted to cure by the radical method cases of inguinal hernia, according to the plans suggested by Wutzer, of Bonn, Wood, and Gerdy—none of which were successful. The patients were improved, no doubt, but not cured, and had still to continue the use of the truss after the operation. He, therefore, devised a plan about eighteen months ago, and performed it successfully on a young man, *æt.* 26, who suffered from oblique inguinal hernia (reducible). He could not find the exact procedure mentioned in any of the books, but still he did not wish to claim any originality for the operation if he was not entitled to it. His plan was as follows:—Having placed the patient on the operating table, and an anæsthetic being administered, the hernia was then reduced, and the skin and cellular tissue of the scrotum was invaginated and pushed up with the finger as high as it would go through the external abdominal ring into the inguinal canal. When in this position a flat needle with handle attached, armed with a stout piece of silk ligature was passed along the finger, fixed in the inguinal canal, and then made to pierce upwards and outwards until it passed through the anterior wall of the canal, so that the eye of the needle was apparent through the skin. The end of the ligature was then caught and secured, and the needle withdrawn. The other end of the same silk ligature was then inserted into the needle, which was passed up along the finger still fixed in the inguinal canal, and passed through the anterior abdominal wall as before. The two ends of the ligature were then drawn up and tightened, and a small piece of bougie about two inches long was then placed between the two ends of ligature which were then tightened and tied firmly across the piece of bougie, close to the point where they emerged from the skin. By this procedure a well marked cœcal canal was formed along the course of the cord by the invaginated tissue. A glass rod was then placed in a solution of liq. ammonia, and then passed into the invaginated canal, so as to abrade the surface, and excite adhesive inflammation or ulceration, and thus finally obstruct the canal. Lastly, a harelip pin or acupressure needle was passed deeply through the tissues transverse to the inguinal canal, and at a point midway between the external abdominal ring, and the position of the ligatures tied over the bougie. Care must be taken, in passing this needle, that it does *not* pass *behind* the cord, but *immediately in front* of the cord. A ligature is then placed over the two ends of the pin or needle and made to firmly compress the tissue between, this pin is allowed to remain until it ulcerated its way out, thereby producing a firm barrier in the canal against the protrusion downwards of the hernia. The ligature over the bougie is also allowed to ulcerate its way out which takes usually three to four weeks. He had performed this operation a year ago, and the man had had no return of the hernia, although engaged in hard manual labour on a farm. In Dr. Franks' cases Mr. Ormsby would prefer to use chromicised gut instead of silver wire, and would on no account leave the wire permanently unheeded in the abdominal wall, as some day or other he believed it would give rise to trouble.

Mr. CORLEY said he had records of a good many cases in which he had endeavoured to effect the radical cure for strangulated hernia. In a debate which took place two years ago on Mr. Stoker's paper discussing Wood's operation for the radical cure of hernia, he took part. Although he had never performed that operation he had seen it done, and having

witnessed the results he was of opinion that the direct operation by dissection was better in theory, and more likely to be successful in practice. Some years ago he introduced to the Society a word invented by an American surgeon, describing the treatment of bullet wounds where the wound was stitched up and the bullet left in its place, as "Ostrich" surgery. It was suggested by the ostrich hiding its head from possible consequences, apparently in the hope that all would be right. It appeared to him that Gerdy's, Wood's, and such like operations were blindfold surgery, especially as most writers were not agreed as to the exact structures that were included. Going on the lines indicated by Mr. Stoker in the present discussion there were two classes of operation, the operation of necessity and the operation of election. There could be no doubt that operating on strangulated hernia they ought as far as possible to make the operation a radical one. That idea was not always prevalent. For the first half dozen cases he operated on himself it was not strongly present to his mind, and he knew it had not always been prevalent in the minds of other surgeons. The other operation was that of election, where there was no strangulation present, where a man suffered from a hernia liable to come down and endanger his life. Here the surgeon had plenty of time to consider what he would do. The principal point to understand was what was to be done and to what extent. Looseness of phraseology had crept into some of the papers; for instance, Mr. Barton had quoted an authority who spoke about the inner ring, which was either misleading or was sheer nonsense; and so too was the expression about the perfect occlusion of the canal, which would imply, as Dr. M'Ardle observed, frequent necrosis of the testicle. Thinking over why some cases were successful and others not, he remembered that Lawrence, in his book on ruptures, published in 1838, had remarked that one of the predisposing causes was an elongated condition of the mesentery, and a lax condition of the peritonæum. Thus the intestines were allowed to swing more easily against the anterior abdominal wall. Lawrence spoke of a number of methods for the radical cure of hernia. One of the earliest and wildest operative procedures was incision—i.e., dividing the integuments and opening the sac after the integuments had been replaced, and then dressing the wound so that it should be healed by granulation. This was in short, the operation for strangulated hernia performed on reducible ruptures. It was, practically speaking, the operation by election. The modern antiseptic plan was engrafted on it which made the exposure of the peritonæum a much more trivial operation as regarded danger. Lawrence wrote:—"In the more difficult and dangerous proceeding of excision, a portion of the integuments was removed and the sac, or a part of it, was cut away. These methods were followed by Celsus, who prohibits operation when symptoms of strangulation are present, and when the swelling contains a large quantity of the intestine. In cases of epiplocele he pushed back the omentum, if it were a small piece; when it was larger he left it out and applied escharotics until it fell off. He says that some passed a needle through the middle of the omentum, and then tied it in two portions. He objects to cutting it away on account of the hæmorrhage." So, therefore, they had to go very far back for the methods adopted at the present day for the cure of the disease. Again, Lawrence observed:—"Ligature and suture of the sac. Several methods have been practised of tying or sewing up the hernial sac, either alone, or in conjunction with other neighbouring parts. Thus some operators having passed a needle and ligature through the skin and under the sac placed a piece of wood between the two ends and then tied them. They drew the knot closer and closer until the included parts had perished. As the spermatic cord was intercepted and the testis consequently rendered useless, the organ was removed, but some professed to include the sac only, and tied the sac. In order to save the testis it was proposed to lay bare and open the sac, and then to sew it up with an uninterrupted suture. This method having for its object to preserve the testis and to maintain it in a state capable of fulfilling its function, that of giving subjects to the king, was styled the royalistic." The subject of necrosis of the testicle was obviously one of those points. His attention was further drawn to the dissecting operation by an operation for varicocele which he performed last winter. He was adverse to doing it, but it was forced on him. The best course, he thought, was to isolate the parts, and when everything was exposed, and in isolating one part from the other there was

the greatest difficulty, so that it impressed on his mind that all the ordinary operations by pin, needle, stitch, and suture were the blindest of blind operations, as well as in the ordinary radical operation for hernia. In connection with the radical cure of all reducible hernia, the point to be considered was how far interference would be justified. It appeared that dread of any operation involving the peritoneum was one of the reasons why a direct operation was said to be undesirable. Abernethy and Petty brought forward their fatal cases of interference with the peritoneum. But as far as he was himself concerned, he preferred for the reasons he had stated, the direct operation. The three papers read were of great value, and the discussion, every member giving his experience, would be of service in the future of this operation.

Mr. HAYES said he had twelve years ago operated on a female who from infancy suffered from inguinal hernia, which could not be satisfactorily supported by a truss. It was not an operation of selection but one of necessity. The patient was in a wretched state, owing to the fact that she was never secure from risk of inflammation. He performed Wood's operation with most satisfactory results. The patient wore a light truss for a short time, but she subsequently dispensed with its use. She married, bore three children, and was seen ten years afterwards perfectly free from any danger of hernial protrusion. A second case was that of a young lad suffering from reducible inguinal hernia, but that could not be reduced by the application of a truss. In this instance also he performed Wood's operation. The result, however, was not so satisfactory as in the first case, the hernia having returned when the boy moved about without the aid of a truss, but when he used a truss which had previous to the operation been ineffective, he was able to support the hernia. Dr. Cruise had twenty years ago performed Wood's operation in the case of a young boy, and he had a letter from him that day stating that ten years after the operation he saw the boy perfectly free from all probability of hernial protrusion, and he had worn a truss from the date of the operation. Mr. Coppinger performed the open operation, exposing the external abdominal ring and bringing the margins of the ring together at the points of suture. Several operations founded on Wood's principle were in vogue, for example, Spanton had devised an instrument to effect the object brought about by the wires or pins in Wood's. There was an operation employed in America and attempted by Dr. Warren, to effect the radical cure by the injection of some irritating fluid within the inguinal canal and round the abdominal rings. He wrote to Mr. Bryant asking for the result, and Mr. Bryant replied:—"Dr. Warren operated upon one case of mine at Guy's for the radical cure of hernia, and the case did well. The man wore a truss afterwards, and six months later the hernia had not been down. I have not done Warren's operation, although Dr. Warren kindly sent me his instruments, as I have not been able to understand the principles of his practice. It seemed to me a mere matter of chance where the injected fluid went. I can hardly compare Wood's with Warren's operation, the former being far more severe. I have, however, performed Wood's when a hernia cannot be kept up by a truss with success. I like Spanton's in theory, and shall give it a trial. I like, better than all, where an operation for the stitching up of the neck of the sac with the pillars (internal), and in some cases of congenital hernia I have cut down upon the sac and done the same." So that Bryant was in favour of the operation by dissection. In performing the operation, Rushton Parker recommended that the neck of the sac should be thoroughly exposed, then drawn down and the sac ligatured as closely as possible to the internal abdominal ring, the further steps being identical with those described by Mr. Stokes and Mr. Corley.

Mr. THOMSON, following Mr. Ormsby's suggestion by adhering to the discussion of the dissection method, said Mr. Corley had properly drawn attention to the fact that the plans that had been referred to were not new. The plan of cutting down upon the sac, upon the pillars of the ring and stitching them, and above all ligaturing the sac and removing a large portion of it, was as old almost as the history of surgery itself. Mr. Corley had also properly mentioned the reason why these methods had been for a considerable time abandoned; but of late years under better methods of treatment the plan of direct dissection had been re-established, and it was far and away superior to any other that had been devised. The question always to be determined in recommending or under-

taking the operation of election was, What was the risk to the patient? Was it justifiable to subject the patient to a risk, whatever it might be, by cutting down upon the hernia, or cutting away the sac with portion of the peritoneum, when perhaps he could get on very well by the use of a well adjusted truss? But before deciding upon that there was the preliminary question whether, if the man were left alone with his truss, and especially if he happened to be of the lower classes, for instance, a labourer, who was to some extent outside the pale of surgical assistance, he might not in the end run just as great, if not a greater risk of strangulation of the hernia and death, than if operated upon under favourable conditions? His own impression was, that given a particular case prepared properly for operation, and understanding that the patient was in all respects favourable, the patient would have a better chance of life by operating upon him and trying to relieve him of his hernia than by the chance of having the hernia strangulated afterwards. In the country he might not have the means of help or the intelligence to recognise the strangulation when it came on, and therefore it was best not only to relieve him from the risk but from the inconvenience of a hernia, if they could, by operating upon him under favourable circumstances. Another question raised was as to the material that ought to be used in stitching the pillars of the ring. He had himself operated on three cases of dissection, and in each he had pursued a different plan. In the first, which was an enormous scrotal hernia of twenty-five years' standing, extending nearly to the man's knee, and so bulky that he had his trousers arranged for it, and yet the tumour could be noticed as he walked along, he cut down on the hernial sac and found it adhering to the ring and parts about. He reduced the hernia and cut away about six inches of the sac, ligaturing the sac itself and leaving a pretty fair stump beyond the point at which the ligature was applied. He did not, however, stitch the ring; because, acting with the concurrence of his colleagues, he believed the stump which was adherent to the parts round about would be sufficient to act as a plug for the opening, and that it was unnecessary to operate on the ring itself. The result was extremely satisfactory, there was some difficulty about his scrotum; he got secondary hæmorrhage from the ulceration of enormous veins, but he ultimately recovered. That was twenty months ago, and he was quite well. He was sent out wearing a truss, and when he last heard of him the hernia had not descended. In another case, a child, twenty months old, had double inguinal congenital hernia. He operated on one side, using chromicised catgut to draw the pillars together. Any attempt to ligature or cut off the sac would be attended with troublesome dissection. What he did was to transfuse the two walls of the sac, and in that way he stitched them together, hoping that sufficient adhesion would be established to help in ligaturing the hernia. The child went out with the hernia up, but after three months returned with the hernia down. He had used chromicised catgut in ligaturing the pillars of the ring; but he would not do so again in the case of an infant unable to control its feelings. The patient was subjected to a second operation on the opposite side six months afterwards. On that occasion he used carbolised silk, and with three or four sutures in a very large ring drew the pillars tightly together. That was in the month of October, and the child went out perfectly well so far as the hernia was concerned. The wound healed, and the hernia had not since returned. He objected to the use of the catgut ligature, because, even though chromicised, it did not last sufficiently long to produce such adhesion in the pillars as would resist the pressure of a large hernia. To obtain sufficient resistance the wire or the silk must be used. Mr. Ormsby and other speakers had objected to the use of the wire. He had no experience of it himself, but the experience of Mitchell Banks, in Liverpool, who had used it for all his cases, a considerable number, was that there had been no trouble whatever with the wire. The wire was simply cut short and became encysted, the wound healing over it, and there was no further trouble. It had been always the aim of surgeons to procure perfect relief from the hernia, and he would have no hesitation at all in recommending operation for the cure of hernia in a suitable case. He believed the danger of wounding the peritoneum, as experience in late years had proved, had been exaggerated so long as the operation could be done under conditions that would exclude from the peritoneum poisonous particles.

Dr. WARREN would exclude the operations for strangulated hernia as outside the debate. The operations of

election were really what they ought to consider as of importance. Having assisted his colleagues in several operations, and from what he saw, the operation by dissection, he felt sure, would be, *par excellence*, the operation of the future. Wood's operation was eminently haphazard, lacking the surgical precision which the other possessed. In the operation by dissection the surgeon had everything displayed, as in the case of a dead body in the anatomical department, and, therefore, there was not much risk. With regard to the treatment of the peritoneum, it could, by adopting the modern method, be handled with an impunity that the old writers never dreamt of, in fact, it seemed to stand more handling than any other part of the human frame. The point had been raised as to whether the pillars of the ring should be approximated, and if so by what means. Some had said that it did not matter whether they were connected so, but that it altogether depended upon inflammatory action excited in the parts. That assertion, however, was not borne out in the operations of his colleagues, for in one of Mr. Barton's cases two metallic sutures were introduced, and the hernia subsequently descended. In another case, two were introduced with perfect success, indeed such brilliant success that a board of public service passed the gentleman for the army, having rejected him before. This was clearly to be attributed to the treatment by the metallic sutures. Despite the objection raised he could not see any to leaving in the wires. In many other surgical operations wires were left in with the greatest impunity. Sir Joseph Lister left wires in in bones. Again, a gentleman, whom Mr. Franks operated on, exhibited himself to some of the members with the wires in the abdominal wall perfectly painless, the hernia never descending and the truss abandoned. Indeed, he was one of the champion bicyclists. As far as the debate had gone the weight of evidence supported the operation by dissection. They had not to deal with the obsolete views of the year 1838, but with the hard, stern facts of 1884.

Dr. BALL said he had, a number of years ago, in North Wales, performed Wood's operation twice. In one case, the result was everything that could be desired, the patient being able to do without a truss and remaining so up to the present. In the other, however, the hernia descended after some time, and a truss became necessary. The truss kept it up, while before the operation great difficulty was experienced. He invited suggestions as to a case he had at present under his care in Sir Patrick Dun's Hospital, namely, that of a young man, *et. 23*, who had a large right and a small left inguinal hernia, which prevented him from following his avocations at the gas works. Having determined on an operation for the radical cure, it occurred to him that an important addition might be made to the dissecting operation by practising on the sac torsion, so that the neck of the sac in the inguinal canal would be occluded by the twisting of the sac. That course, if practicable, presented several points of great utility. First, there would be a thick cord instead of an open cavity in the inguinal canal; and secondly, as Mr. Corley had remarked, one of the great predisposing conditions to the formation of hernia was the very lax condition of the peritoneum in the inguinal region, and the twisting would undoubtedly tighten the peritoneum at that point and so render the occurrence of hernia less likely. Judging from two or three cases which, as Demonstrator of Anatomy in Trinity College School, he had carefully dissected, he did not think there would be any insuperable difficulty in practising torsion, but, of course, the practicability of the procedure could only be decided by operation. What he purposed doing was to expose the neck of the sac, pass a ligature round it, ligaturing it tightly, and then twist the neck of the sac and pass a suture through the pillars of the ring and through a twisted cord to prevent it becoming untwisted. Another important point was that he believed the liability to septic peritonitis would be considerably diminished. Supposing there was septic inflammation at the twisted point it was improbable it would spread by the closely opposed surfaces of the peritoneum without producing limited adhesion; and secondly, the danger of diffuse peritonitis would be, to a considerable extent, diminished.

Mr. O'GRADY did not know whether anybody had had a fatal case except himself. No doubt the practical effect of the present discussion would be to largely increase the number of hernia cases operated on, especially of young children, as the operation grew in popularity. In his case he had several

years ago operated on a young fellow, making an incision in the skin, invaginating the superficial tissues underneath and sewing them and the pillars of the ring together. Nothing untoward attracted his attention at the time of the operation; but after some days the wound suppurated, large quantities of urine were discharged from it, and the child died. It was perfectly obvious that the needle had gone through the bladder. Anyone who reflected on the anatomical formation of the bladder would see how such an occurrence could take place. He was not aware that the accident was alluded to in the text-books. In future cases he had taken the precaution to empty the bladder. He hoped that the statement of his experience would be the means of preventing the recurrence of a similar accident. In favour of the operation he was forcibly struck by Mr. Thomson's argument for operating at a propitious time, and to save the patient from the increased peril in after life of the hernia becoming strangulated, when the sufferer might be beyond the reach of surgical relief. The cogency of that argument was brought home to himself in the present month, and again last September. On both occasions he was telegraphed for, and on both his visit was countermanded. In the first case death was accelerated by a danger not yet alluded to, namely, the treatment of strangulated hernia by liberal doses of croton oil. To a certain extent he agreed with the President that no case could be looked upon as successful that had not been a number of years submitted to the test; for how could they expect that a patient operated on would be a better man than a man sent out of Nature's factory? The recurrence of hernia should not be a bar to the operation, and if they put a man in a position so that wearing a truss would prevent the hernia from coming down, they would do him great good. On the whole, he thought the operation ought to be done more frequently than it was at present. With regard to the question of the wire, there was no knowing when a metallic body in the human frame might become a source of irritation. As to the accident he had mentioned, he found a ready means of obviating a similar result by emptying the bladder. Hutton had mentioned a case of an adult in which a catheter could be passed through the bladder into a hernia, and felt protruding into the groin. Thus not only in a child but an adult might the accident happen of penetrating the bladder.

Dr. Foy observed that a similar accident had occurred to Potts. In cutting down on an inguinal hernia he came on the fundus of the bladder.

Mr. NIXON called attention to the operation devised and practised with success by Fitzgerald, of Melbourne.

Mr. THOMSON inquired whether Mr. O'Grady used his left finger when passing in the curved needle, or what was done to protect the bladder?

Mr. O'GRADY said he did, otherwise, he could not invaginate the tissues.

Dr. ASKE said he had seen several operations performed in the City of Dublin Hospital, most of them upon young children, and with the strictest antiseptic precautions; but in the case of young children the operation, as an antiseptic one, must be more or less of a failure, as there was great difficulty in keeping the dressing applied. Children had as utter disregard for Sir Joseph Lister, and obeyed the calls of nature without any attention to his dressings. The cases not being his own, he could talk about them in a disinterested manner, and state that the hernia returned, and nearly all of the patients went out of the hospital wearing trusses. Some of the patients afterwards returned. A radical cure meant a cure, and, where a truss was worn there was not a radical cure. Again, where the pillars of the ring were united by silver wire, he could not regard them as united by anything else, and, so long as the silver lasted there would be a radical cure. He did not consider radical cure had been effected in Mr. Stokes' cases, the operations not having been performed sufficiently long to say so.

Mr. STOKES in reply to the various criticisms during the debate said, Mr. O'Grady had done good service in striking a note of warning as regarded the danger that attended the operation. In connection with the division as to operations of election and operations of necessity, sufficient attention had not been paid to the difficulties and dangers attendant on operations for any of the congenital forms. One of these difficulties had been mentioned by Mr. Aske, namely, that of keeping the wound aseptic. Everything he had said on that point he endorsed, and it had also been dwelt upon by one of the greatest antiseptic surgeons living,

namely, Prof. Volkmann, of Halle. There was also the danger of injuring the constituents of the cord. The danger of injuring the vessels was great, and likely to be followed by necrosis of the testicle. The startling statement had been made by Krascha that where such a condition existed in order to produce a perfect radical cure it was better to sacrifice the testicle on that side. In his opinion, under no circumstances should it be contemplated except there was reason to believe that the function was destroyed by atrophy, and in young children it was not easy to say whether or not it was in that condition. At the age of puberty a good idea could be formed as to whether the testicle was in that unhappy condition, but until the surgeon was satisfied it existed he would not be justified in sacrificing it. In reference to Mr. Ormsby's practical remarks in favour of chronicised catgut for ligaturing the rings, that was the material he had used in the operation in which he had failed to effect a radical cure; and he had determined undeterred by what he had heard to use in his next case metallic sutures. He had used them in other operations, and no irritation or trouble ensued. Mr. Corley quoting from Lawrence's book had described the operation of cutting down on the sac and leaving the wound to granulate, and this he stated was similar to the operation of dissection. In that conclusion he did not agree. There was a great difference between the two modes of procedure, the cutting down and suturing the neck of the sac and the pillars of the ring. While he agreed with Dr. Warren's statement as regarded the silver sutures, he could not agree with his assertion that Wood's operation was haphazard. Although not particularly enamoured of Wood's operation in consequence of its being so complicated and difficult of performance, the word haphazard was the last that ought to be applied to it. With reference to Dr. Ball's suggestion of torsion, he would like to know what became of the distal portion of the sac. If he seized the sac, and separated it from the surrounding parts the distal portion of it would probably slough and instead of having an aseptic wound there would be the reverse. He could understand the procedure if he coupled with twisting excision of the portion of the sac.

Dr. BALL said that was what he intended to convey. He purposed excising the sac immediately below the ligature.

Mr. STOKES, continuing, remarked that that made the procedure different, and it ought to answer very well. With reference to the peculiarities of congenital hernia, he could not understand how any surgeon could propose ligaturing the sac under such circumstances, having regard to the danger of tearing the vessels, and also to the fact that necrosis and destruction of the testicle might follow. As to his own cases, he agreed that a sufficient time had not yet elapsed to regard them as radical cures, but where eight, nine, and twelve months had, in fact, elapsed since their treatment, he was justified in stating what result had been obtained so far, and it must be remembered that it was extremely difficult to follow hospital cases once the patients left hospital.

Mr. BARTON, in replying, recalled attention to the question he had raised, whether the plan of invagination should now be superseded by that of direct closure of the ring. The invagination plan came to its climax, and got its best exponent in Wood's operation, which combined to some extent the closure operation. But was the invagination a procedure that ought to be pursued still further? or were they on the right tack with the operation of closure? That would be decided by the future record of operations. On the question of the kind of suture, nothing he had heard had changed the feeling which had induced him to employ a metallic suture, the statements being wide and irrelevant. In order to make the sutures as little dangerous as possible, exceedingly minute care should be taken in the operation to see that they were safely placed. For instance, it would not do to have the twisted end jagged, or rough, or projecting against muscles expected to move up and down with the play of the abdomen. Care must be taken to have the twisted end turned down, and placed so that the lymph might be expected to close round it. He still thought it was with silver wire they might expect the greatest success. In the future Transactions of the Academy they might be able to add, not only all the cases favourable, but unfavourable, following the excellent example of Mr. O'Grady, and thus reliable data would be obtained.

Mr. FRANKS also replied. In reference to the treatment

of children, Dr. Buchanan adopted an effective measure. When the dressings were applied, he bandaged the child to a St. Andrew's cross. In two cases in which the method proved successful, he kept the children each fixed firmly to the cross for three weeks, and by that time the wound had healed. In the cases of election the operations recommended were the open or closed method. The open had an enormous advantage over the closed, the surgeon being able to see everything he did. At the British Medical Association in Worcester, in 1882, Spanton, detailing his cases, mentioned thirty-four in which he operated by his method. The operation should only be done on the young and healthy. Of the thirty-four, twenty-two were cases under eleven years of age, and the oldest of the cases was aged 27. The case Mr. Thomson mentioned of the enormous hernia that could be seen in the trousers was a good deal older—viz., 50. He had been tempted to perform castration, as recommended by Krasche, in a case of 50, the testicle being atrophied. He did not agree with Mr. Thornley Stoker, who laid a great stress on the amount of lymph exuded in approximation of the pillars. It could not be contended that, to keep a man outside a window, closing the window would be as effectual as closing the shutter, and in addition putting a couple of iron bars across. In the radical cure by the open method it was impossible to say that a layer of lymph could offer the same amount of obstruction to the descent of hernia that exuded lymph and approximated rings and silver wire would afford. As to the harm of the wire, there was not a single case on record in which it had done any harm. Accordingly, the objections to the silver wire must be looked upon at present as theoretical. From what he had seen and read, he believed the open method of operation would be the operation of the future.

The Section then adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MONTHLY MEETING.—FEBRUARY 1ST.

Dr. THUDICHUM, President, in the Chair.

Mr. KEETLEY showed cases of

AMPUTATION THROUGH THE KNEE-JOINT OF PIROGOFF'S AND HEY'S AMPUTATION;

and he also showed (by permission) the patient in whom the late Mr. Shuter had dis-articulated at the hip, sub-periosteally. Mr. Keetley contrasted the chief arguments for and against amputating through the joints of the lower extremity. When a distal segment of bone was left, e.g., in Pirogoff's and in Gritti's amputations, he strongly urged that it should be wired to the proximal bone, and he showed that otherwise it usually became retracted and a source of tenderness in the stump.

Mr. LUNN dwelt upon the necessity of leaving the periosteum in all cases.

Mr. THOMPSON spoke in favour of the Beaufort artificial limbs, specially as regards their light weight.

Mr. BENTON asked Mr. Keetley if it was his custom to save the patella when amputating the knee-joint, and also asked his opinion as to which were better, to make a long anterior flap and short posterior flap, or *vice versa*; remarking that he himself had found that the long anterior flap was often attended with much sloughing.

Dr. THUDICHUM inquired Mr. Keetley's opinion as to the exact fate of the cartilage in the case of a successful amputation of the knee-joint, and remarked upon the advantages of wiring the stump, as it afterwards became the more serviceable.

In reply, Mr. KEETLEY said that he thought the artificial limbs lately exhibited by Mr. Thompson, viz. (the Beaufort artificial limbs), might be well adjusted to a patient whose hip had been disarticulated, if only it were made to take a firm hold of the pelvis. An artificial limb, for an amputation at or near the hip, should make use of the pelvis, exactly as an artificial leg, for an amputation at or near the knee, uses the thigh. With regard to saving the patella, he was opposed to it, unless a Gritti's amputation was done, and the freshened surface of the patella applied to the sawn surface of the condyles. He believed the changes in the cartilage, after a successful disarticulation, were identi-

cal with those which occurred in cases of unreduced dislocation.

Dr. P. ALDEN OWLES reported on the progress of a case brought before this Society, in April last, by Dr. Drewitt, who showed it as a case of

GENERAL PARALYSIS OF THE INSANE,

but at the meeting, however, Dr. Forbes Winalow and others thought it a case of simple aphasia, which would probably pass off in about six months. The patient shortly showed signs of improvement, both in walking and speaking, and obtained a position as butler. Six months later he was seen by Dr. Owles, who found him getting much weaker, apparently from over exertion, though in walking and speaking he had improved, and there were no symptoms specially characteristic of general paralysis of the insane. On some points his memory did not seem quite correct, but the confusion was not more than is general in those who have impaired their brains with the abuse of alcohol and other excesses. He was then for some time an out-patient at the National Hospital for the Paralyzed and the Epileptic, where he was under Dr. Ferrier, who reported that he found the symptoms to be those of general paralysis, very general tremulousness, defective articulation, and unequal pupils, but without any very well marked mental symptoms. The treatment was bichloride of mercury with perchloride of iron. The patient then went to St. George's Hospital, where basic pneumonia first showed itself, and in three days he died. The doctors at that hospital reported that they saw no symptoms of aphasia or paralysis. No post-mortem was allowed, but Dr. Owles thought the following conclusions probable: 1. It was not a case of general paralysis of the insane; there was an absence of the most prominent symptoms. 2. If it was a case of aphasia, the aphasic symptoms, as Dr. Winalow expected, had almost disappeared in six months. 3. Though there was no proof of syphilis, there was evidence of alcoholism, and it seems likely that this was the predisposing cause, both of the symptoms of paralysis and of the double pneumonia, from which he died.

Dr. THUDICHUM considered that, except in cases of syphilitic history, the use of mercury was disadvantageous, owing to its tendency to accumulate in the tissues.

Dr. DREWITT admitted that he had great doubts on the exact diagnosis when he first saw the case, still he did not think it necessary to have distinct mental symptoms, as that depended greatly on the situation of the disease.

Dr. BENNETT spoke of a case of alcoholism, the symptoms of which simulated those of general paralysis of the insane, and which got well under treatment.

Dr. OWLES then replied.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

MEDICAL TITLES.—There is in France but two medical diplomas, that of *officier de santé* and doctor. The first named title is given to those who, from various reasons, cannot take out the higher degree, the powers conferred on the holders of the diploma are limited, the *officier de santé* cannot perform any major operation without the presence of a doctor (a needless injunction), he cannot hold any hospital appointment, and he is confined to a Department of his own choosing, if he leaves one place to go to another outside the radius marked on his diploma he has to pass a new examination. Of course it is understood that otherwise he possesses all the advantages attached to the profession, and his success as a general practitioner is in no way lessened if he has talent enough, but he is generally looked down on by his *confrères* possessing the highest degree, and often subject to petty annoyances which he has to digest as best he can. However, as regards foreign medical men who come to settle down in France, this diploma is of great value as it confers on them, and with very little trouble, the right to practice, which, otherwise would be refused them unless they were well known

"stars" of the profession. To the English medical man of ordinary merit leave is granted by the Government to go up for the diploma of *Officier de Santé* without any delay, and as the examination is very easy and purely practical, the difficulty is *nil*. . . . When he passes he is not considered by his *confrères* as an *Officier de Santé*, but takes rank amongst them as a properly qualified man and enjoys all the advantages of an M.D. of Paris. Of course, as a foreigner he cannot enter any state department nor can he compete for any public appointment. It has been long attempted to abolish this title of *officier de santé* and to establish but one degree in all France, but without success. The difficulties in the way of such a reform being found to be very serious. For instance, no man is allowed to enter on the study of medicine in view of the doctorate without the certificate of *bachelier es lettres et es sciences* which is equivalent to the B.A. of British universities. Now, there are a great many young men who have a marked taste for the profession, but who do not, although fairly educated, possess the means necessary for the taking out of this certificate, nor that of spending five years at a Faculty, and they are glad to have the opportunity of entering the profession by this back door. Also there are towns where schools of medicine are situated, which contribute not only to the public good but to medical science in general, and which would have to be closed if such a law passed, and, although, they are only for turning out *officiers de santé*, are controlled by professors of great merit. However, a doctor who is a member of Parliament has laid on the table a bill for the abolition of the title, but in a manner which may render its adoption possible. It also regulates the admission of Foreign medical men to the doctorate.

TUBERCULOUS GANGLIONS OF THE NECK.—At the *Société de Chirurgie*, M. Trélat communicated several cases in which he operated successfully for tuberculous ganglions of the neck, or the axilla, and he was of opinion that it was very far from proved that the operation was otherwise than feasible when circumstances were favourable, and the instrument he employed was the curette. M. Desprès was inclined to agree with M. Trélat, but with some reserve. When other treatment was tried in vain and the ganglions caused trouble to the patient, the ablation was rendered necessary, but otherwise he would respect them. In any case it was difficult and often impossible to remove all the tumour, and septicæmia was then rendered probable. The rational treatment would be blistering, painting with tincture of iodine, the actual cautery and cod-liver oil. M. Verneuil preferred total extirpation to every other method when medical treatment failed. Other members took part in the discussion, and in the end a majority was found to be opposed to the opinions of M. Trélat.

At the *Société de Biologie* M. Pozzi presented a young girl who, although having a vulva well formed with a hymen had neither vagina nor uterus, and accompanied the presentation with some remarks on the real origin of the hymen. In his opinion this membrane depends from the vulva and not the vagina, as was the opinion of Budin. Further, he considered, that that portion of the genital organs commonly called the bulb of the vagina as the analogy of the urethral bulb in man was nothing more than a rich plexus of vessels. These ideas were opposed by several members who thought that M. Pozzi wished to subvert all the universally admitted theories of the development of the female genital organs.

PARALDEHYDE.—The *Société de Thérapeutique*, through M. Baumeiz, furnished some new details on the properties of the anodyne agent called *paraldehyde*. From experiments made on rabbits it seemed that there existed a pronounced

antagonism between the agent already named and strychnine. He administered a dose of strychnine to one rabbit sufficient to kill twenty-five of the species, after having administered a large dose of paraldehyde, without producing death. A few weak convulsions were all the manifestations of the toxic agent. The experiment was repeated on other animals with the same result.

BICHROMATE OF POTASS AS AN ANTISYPHILITIC has for partisan in Saxony Dr. Güntz, and in France Prof. Vulpian. The former employs it in solution charged with carbonic gas, as follows :—

Bichromate of potass, 2-3rd gr.;
Nitrate of potass, 2 gr.;
Nitrate of soda, 2 gr.;
Chloride of sodium, 4 gr.;
Water charged with gas, 5xx.

M. Vulpian also recommends it in dyspepsia depending on a catarrhal affection of the stomach simulating carcinoma of that organ. He prefers it in the form of pills :—

Bichromate of potass, 1 gr.;
Extract of valerian, 10 gr.

Divide into 5 pills. One, two, or three in the day.

It will be remembered that it was Prof. Vulpian who attended the late Count de Chambord, and having recognised the disease as catarrh of the stomach, prescribed these pills, but, it must be added, with little result.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 12, 1884.

THE RADICAL CURE OF HERNIA.

THE Surgical Section of the Academy of Medicine in Ireland has lately been engaged in considering a subject

which has long held a position of first importance in modern surgery, and respecting which the ablest operators of all countries have striven to effect improvements. Among those affections of the human body that call for remedial interference none, probably, has so much exercised the minds of professional men as rupture; and we have abundant evidence of this fact in the dissatisfaction, as often evinced, with those operations hitherto devised with a view to promoting radical cures of herniæ. It was therefore with a certain prospect of advantage that a full discussion of the subject was initiated at the Irish Academy; and the result of the debate may safely be regarded as a positive gain to knowledge.

Mr. William Stokes, Mr. Barton, and Mr. Kendal Franks each read a paper in which operation by direct exposure of the parts contained in the canal and the introduction of sutures was advocated, the details varying only in the respective modes of procedure adopted. Mr. Franks, however, especially describes a plan by dissection, in the two modifications of which suture of the abdominal openings is recommended, but in one case the sac of the hernia is previously removed by excision, while in the other this is not interfered with. In carrying out the operation a cut is made straight down upon the hernial tumour, and the sac carefully exposed after its return within the abdomen, and the opening in the abdominal wall then drawn together by two or three stout silver wire sutures. These last are directed to be left permanently *in situ*, a proceeding to which Dr. Thornley Stoker raised emphatic objection as being unscientific and unsurgeonlike, and likely to cause future trouble in case of any recurrence of rupture.

The consensus of opinion, however, was generally favourable to Mr. Franks's plan; and it may be said in this connection that the difficulties foreseen by Dr. Thornley Stoker are rather fanciful than real, inasmuch as successful operation implies effectual cure, and any return of the hernia would be little likely to occur until such changes had occurred in the neighbourhood of the sutures as would suffice to prevent their being a source of dangerous irritation subsequently. Another objection, raised by Dr. McArdle, is more formidable, to the effect that phlebitis may be induced by the pressure required to bring the edges close together and retain them; but with careful attention to the position of the sac, and avoidance of its anterior face, this misfortune ought to be sufficiently prevented; and by following Mr. Lambert Ormsby's suggestion to replace the wire suture by catgut it would be unlikely to arise, though thereby, probably, one important requirement of Mr. Franks's mode of operation would be lost.

Mr. Stokes's operation is one which would have been impossible before the era of Listerism; and it affords a striking illustration of the marvellous benefits conferred on surgery by the great master of antisepsis. It consists of a double system of sutures, one set for the peritoneum the other for the external abdominal ring. As many sutures of carbolic catgut as may be required by the dimensions of the neck of the sac are inserted through the latter, this being open and in a situation close up to

the external abdominal ring; next, two or more sutures of stronger material, which may be silver wire, are employed to approximate and close the canal by bringing the pillars of the external ring into apposition. Of the four cases thus operated on, one returned after three months with the hernia once more down; and this occurrence being imputed by Mr. Stokes to employment of sutures of deficient strength, he decides that for closing the pillars of the ring either carbolised silk or silver wire can alone be relied upon.

Mr. Barton's principle of operation is to entirely close the internal ring and so prevent any future possibility of a descent of the hernia. Silver wire, which is to be left *in situ*, is recommended by this gentleman also, and ablation of the sac forms a necessary part of the operation in many cases. Like the other surgeons who contributed papers at the commencement of the discussion, Mr. Barton had successful cases to recount; and broadly surveyed, the plan of each presents obvious advantages to recommend it.

The main feature of the whole debate, however, is that successful treatment of rupture is possible when carried out with the aid lent by antiseptic surgery; and further, that those surgeons obtain the best results who, at the outset, recognise the fact that natural barriers alone are insufficient to preserve a rupture from future descent. All the older methods of treatment, pursued, as we must not omit to remember, in the absence of advantages possessed in the present day, depended for their success on inflammatory changes leading to occlusion of the inguinal canal or parts of it. The frequency of failure under these conditions is to be explained by the fact that organised lymph can never offer persistent resistance to a constant pressure, and must in time yield to the pathological law which regulates the sequence of events in such a case—with consequent reproduction of the hernia. As these necessary results have gradually been recognised, we have had suggested improvements on the plan which secured them, and Mr. Spanton's ingenious device for closing the canal may be regarded as among the most efficient in this respect. Like its predecessors, however, this method lacks the thoroughness and security obtained by resort to direct display of the parts to be interfered with, the absence of which condition almost deserves the epithet applied by Mr. Corley to operations for radical cure of hernia in the past, and which he described as the blindest of blind proceedings.

Mr. Stoker very appropriately defined two classes of cases in which the operation for hernia is called for, viz, those in which it is compulsory, as in strangulation, and those in which it is resorted to for convenience. In large inguinal rupture he admits the necessity of peritoneal suture, but in such cases as come under the second category, those of election, he advocates resort to Wood's operation, and sees no advantage in drawing the pillars of the ring together, trusting entirely to the barrier of coagulated lymph which results from the operation. Notwithstanding this opinion, however, it is very likely that expediency will exert a very powerful influence on the decision as to need for radical cures of herniæ; and that surgeons generally will prefer to

reduce their risk of failure, by resorting to one or other of the direct methods which have now been shown both to promise good prospects of success, and to be surrounded with no serious elements of danger to the patient.

On one point the discussion at the Irish Academy of Medicine is non-instructive, that, namely, of mortality. One speaker only, Mr. O'Grady, contributed notes of a fatal case, and it was of a very instructive kind. He had operated some years since on a young man, by invaginating the superficial tissues and sewing them to the pillars of the ring. A few days later suppuration occurred, and urine flowed in quantity from the wound, when it became obvious that the needle employed in making the sutures had penetrated the bladder. Such an accident could scarcely happen when any one of the modes of operation involving dissection of the parts was adopted; but it is well that it has been brought to mind at this period of the history of hernial surgery.

Without assuming to dogmatise on the question, it is allowable for us to believe that older methods for radical cure of hernia have been tried and found wanting; and that the improvements by which they will be replaced subsequently are destined to be accompanied with much more valuable and lasting benefits than have been obtained in the past, while the main instrument in effecting such change is found in the immunity conferred by antiseptic surgery.

THE PARASITES OF THE BLOOD IN HÆMATOCHYLURIA.

THE subject of hæmatochyluria has recently received a good deal of attention from medical scientists; and during the past year, in an interesting and instructive article, Scheube epitomised the main features and facts concerning the affection. M. Comby (*Bulletin*, 14th July, 1883) likewise drew attention to the symptomatology and geographical distribution of hæmatochyluria.

The embryonic animalcular forms which exist in the blood in hæmatochyluria consist of cylindrical, elongated forms, smooth, and enveloped in a structureless membrane, and without any apparent organisation, if we except a double ray occupying the middle region of the body. The anterior extremity which, rightly or wrongly, has been called the head, is prominent and rounded; the posterior extremity, or tail, is tapering, and terminates by a vibrating process which subserves the purpose of progression, as the filament of the spermatozoid. It is obvious that the organisation of these rudimentary forms, however superior they may be to microbes, is yet very low. On this point observers are agreed. It is, however, differently with respect to their dimensions, on which the most diversified estimates have been recorded. Scheube appears to have arrived at more accurate conclusions on this point than any other authority. During a sojourn in Japan he studied carefully the question, and he attributes to them a length of 216,000th of a millimetre, and a circumference of 0.004 thousandth only. Their number in the urine and in the blood is exceedingly variable.

Within the past few years Manson (at Amoy) made some very curious and interesting observations on the origin and development of these parasites. According to this authority, the embryos of the *filaria sanguinis* never attain to full growth in the human body. They seem to abandon man for a medium more propitious to their growth, but not without the hope of return. They find in mosquitoes a place of temporary sojourn. The male mosquito has no sting, and does not live on human blood. It is the female mosquitoes alone which attack human beings, and which thus absorb with the blood the embryos of the *filaria*, and which are found in their stomachs in considerable abundance. The greater portion of them are partially digested, while the remainder grow in a space of time not exceeding six days so large as the 1-15th of an inch. Henceforth these are visible larvæ, active, and of more complicated organisation, for they possess an intestinal canal, and their cephalic extremity is furnished with organs of perforation, by which they ultimately re-enter the human body.

The female mosquito deposits its eggs on the sea border, and dies. The larvæ of the *filaria* then become free. Manson supposes that most frequently they obtain admission into the human organism through the stomach, being contained in the water, which is never filtered, drunk by the natives. It is admitted by him, likewise, that they are able to penetrate the skin and thus reach the blood, as he believes happens through bathing in water infested with these larvæ. However introduced, they seek in the human body a field more suitable for their existence than the intestinal mucous membrane or the sub-dermic tissue, and this being found, they multiply. All this, according to Manson, it is easy to prove, as he has frequently satisfied himself in the following manner: A Chinese afflicted with hæmatochyluria was enclosed during the night in a mosquito net, one side of which was left open for a few minutes. A light placed by the side of the subject attracted the mosquitoes, and as soon as they were present in sufficient number the net was shut and the light extinguished. The following morning Manson collected with ease the mosquitoes gorged with the blood of the subject, enclosed them within suitable vessels, and followed step by step the successive development of the *filaria*, of which their stomachs were full.

Cobbold completely accepts the conclusions of Manson, but Leuchart and Lewis express doubts. The latter, for example, admits that the embryos of the *filaria sanguinis* pass into the stomach of the mosquito and there undergo certain transformations. He has seen the stomach of the mosquito contain young hematodes, which may be an ulterior state of development of the embryos absorbed; but he contends that absolute proof of this is wanting. Further, the experiments of Manson have failed in other hands. Thus, Myers (at Formosa) caused monkeys to drink of water in which the mosquitoes had laid their eggs, yet these animals did not contract *filaria*. It is, however, true that the mosquitoes of Formosa are a different species to those of Amoy; and Myers admits that the former do not offer a favourable nidus for the development of

the embryos, which become totally developed in their stomachs. It is thus that *filaria sanguinis* is not epidemic at Formosa while it is at Amoy.

The adult parasite in the human body is a rarity. Bancroft, however, states that he has observed it attain to the size of four inches long in the human body; and in this case it has some resemblance to the *filaria* of Medina, which, under certain conditions, attains to dimensions even more considerable. There are still some problems presented by this subject, difficult to solve. Thus, why are the embryos of the *filaria sanguinis* so abundantly distributed in the blood during the night? Why are they so rare during the day? It seems probable that each night a new generation is begotten, to disappear the following day. It is certain that during the day these parasites are hidden in some parts of the economy inaccessible to the experimenter. As to the spontaneous elimination of the embryos of *filaria*, this is accompanied by the various channels of secretion and excretion; they are found especially in the urine, but sometimes even in the tears.

THE CASE OF THE SENIOR SURGEONS-MAJOR, ARMY MEDICAL DEPARTMENT.

As the efficiency of the army depends upon the zeal and ability of its regimental lieutenant-colonels, so undoubtedly does that of the Medical Department upon the excellence or otherwise of those senior executive officers who hold the most responsible charges of our military hospitals. Now, what is their position? A hopeless block in promotion; an ill-defined rank in the service; nothing to show to the public when they leave it that they have spent more than a quarter of a century in her Majesty's my; and an increasing shortness in the term of home service without any corresponding reduction in the period required to be put in abroad; to which may be added the want of charge pay that existed under the old regimental system in India. That these are fair and legitimate grievances can be shown without much difficulty.

In the nine years previous to 1873 the average annual strength of medical officers was 1,048; during the last nine years, since the introduction of unification, 880, or 168 less. The Government having thus gained largely at the expense of the comfort and health of its medical officers, the least it may be asked to do is to remedy those evils which they justly complain of. Dr. Boileau, in his admirable set of tables, has shown that previous to 1874 the rank of deputy surgeon-general was obtained at an average age of 48.5 years, and 25 years' service, while many officers were promoted much earlier. Of late, things have come to such a pass that a large proportion of the brigade-surgeons can never hope to reach the rank, or the senior surgeons-major that of brigade-surgeon, until they are nearly fifty years of age and thirty of service—a sharp contrast to the recommendation of the War Office Committee, of which the late Director-General Sir William Muir was a member, that in the interest of efficiency this rank should be reached at 22 years' service, and that of deputy surgeon-general at 48 years of age. The ill-defined rank of surgeon-major ranking with lieutenant-

colonels is also a just cause of complaint. An officer is at least entitled to ask that his relative rank should be properly put before the army and the public, and that officers of 20 to 30 years' service should have as distinct a title in the army as their brother fleet surgeons have in the navy. Under the Royal Warrant of 1858 many of the present senior surgeons-major would have been entitled to the honorary rank of deputy surgeon-general on retirement, while now they can only obtain that of brigade-surgeon—a meaningless designation conveying to the outside public no defined military rank whatever. Had these officers (as originally suggested) been called assistant surgeons-general, it would have been infinitely more satisfactory to all parties. The impolicy of withholding charge pay to medical officers in India is self-evident in face of the fact that the Indian Government have saved so largely in numbers and forage allowance, and that command pay is given to every officer holding an independent responsible position in that trying climate. It is of the last importance to the medical service that the evils we have pointed out should be grappled with in a common sense kind of way. A small present increase in the number of brigade-surgeons would bring down the rate of normal promotion to 25 years' service at most. There is a precedent for this in the course recommended by Sir Galbraith Logan in 1873, when the then senior assistant surgeons were verging upon 16 years' service, and acted upon by the Government. We believe Sir James McGrigor had to adopt a similar course when he obtained for the old regimental surgeons of his day the new rank of second class staff surgeon as a "fillip towards promotion." We could never see any reason why medical officers of 20 years' service should not be styled surgeons-lieutenant-colonel, being just as *apropos* as surgeon-major or surgeon-general. This would have the great advantage of at once defining the relative military status of the officer without ignoring a profession of which they are justly proud. Some better name may be suggested, but we doubt it. Why the officers of the Medical Department should not have the same proportion of home service as have those of the chaplains, commissariat, and combatant branches, is a mystery not difficult to solve, being a simple question of numbers. That the present short term of home service is much felt by the senior members of the Department who have borne the brunt of the fight against climate and disease is only too evident from what we hear around us. That Dr. Crawford has at heart the well being of the service of which he is so distinguished a member we have no doubt. We hope he will see his way to remedy the grievances we have pointed out.

Notes on Current Topics.

Nightmare.

It is a little remarkable that medical men have given such scant consideration to the subject of nightmare, which as a nosological entity certainly holds no place in medicine, and yet the probability is great that this condition possesses an importance that demands appreciation, and this view is defended in a recent issue of the *Philadelphia Medical Times*, by Dr. George Hamilton, who

remarks that it is well nigh impossible to determine, in the numerous instances where persons, apparently in good health, retire to rest at night, and yet are found dead in the morning, how many of them have succumbed to attacks of nightmare. The almost invariable custom in such cases is to give a certificate or render a verdict of apoplexy or disease of the heart; whether there has been a post-mortem examination of the body or not; or should a more than usually impressionable jury be empanelled, the record will be "Died by the visitation of God." The pathology of nightmare can lay some claim to acceptance, inasmuch as its victims are usually persons suffering from some form of cardiac mischief; and in cases of long standing it is quite possible to understand how nervous complications, such as partial paralysis, may be sequential to an attack, owing to implication of the brain and cord through continued derangement of the circulation. There is good reason for believing that an attentive study of nightmare in all its relations would be productive of valuable results, and it offers a field which has not hitherto been worked.

Medical Society of London.

THE annual meeting of the Medical Society of London was held on Wednesday, March 3rd, when an election of officers and council for the ensuing year took place. The state of the Society is of the most encouraging description, and is more flourishing than it has been during any previous part of its existence. The interest taken in it by the profession is shown by the considerable accession of members which has recently been announced; and in the scientific work performed by the Society of late is every indication of considerable activity in the way of producing papers of permanent value. Many of the discussions, too, which have been conducted at the Society, have exerted a marked influence on the progress of medicine, and those on rheumatic fever, catheter fever, and the treatment of enteric fever by cold bathing will be long remembered in this connection. The Society enters on a new year of its existence with every prospect of increased success and usefulness.

The Dalrymple Home.

THE first annual meeting of the Dalrymple Home for Inebriates took place at the Mansion House last week, when a report of the working of the Home for three months was presented. From this it appears that seventeen patients have been received during the quarter, nine being committed under the Habitual Drunkards Act. Four of these voluntarily consented to resign their liberty for the full period allowed by the Act—twelve months, four others for three months, and one for nine months. The eight remaining patients entered the institution privately. It is gratifying to hear, as is stated in the report, that no trouble has been experienced on the score of drinking, the more so as some little unpleasantness might very reasonably have been anticipated in this connection. Stimulated by the success of their undertaking [so far, the committee now make an appeal for funds to carry out an extension of their premises, a step, however, which might perhaps be better deferred until

more permanency in the result has been shown. At the same time every encouragement deserves to be given to the effort simultaneously made to found a home for destitute women; and this movement will doubtless command the sympathy and support of many who might hesitate to promote extension of the male home until further trial has proved that it will be a lasting success.

Hospital Pupils as Deputy Prescribers.

At some large hospitals, chiefly, we believe, in the provinces, it is customary for physicians, when making their rounds, to dictate prescriptions to pupils having charge of the cases. This plan possesses many disadvantages, and is attended with some amount of risk to the patients themselves, as was shown by a distressing accident which occurred a few days ago at the Gloucester Infirmary. Dr. Washbourne, physician to this institution, ordered a sleeping draught for a woman suffering from bronchitis, and directed the clerk to the case to write on the board a prescription containing one drachm of syrup of chloral. Under the impression that the syrup and actual chloral were the same, the pupil ordered a drachm of the latter, and this, by some unaccountable negligence, being supplied by the dispenser, the unfortunate woman who took it naturally died. At the inquest which followed the jury appended to their verdict a rider "that the system disclosed by this inquiry as existing at the infirmary, with reference to the dictating of prescriptions without any signature of any responsible medical officer being appended is a very dangerous one, and one which should be remedied forthwith; and we also consider that in cases of special prescriptions there should be some communication between the house-surgeon and the dispenser on the subject."

Women Students at Oxford.

In a recent congregation at Oxford a proposal was made to allow women to enter for the same honour examinations as men, and, contrary to expectation, it did not meet with any very strenuous opposition, having passed by 100 votes to 46. It will come before Convocation to be confirmed this week, and there is every likelihood that it will here also meet with success. Under this rule both classical and mathematical honours at the moderation examination will be accessible to women, and the final schools of natural science, history, and mathematics.

Garlic in Hydrophobia.

ALTHOUGH numerous remedies have been proposed from time to time for the cure of hydrophobia, hardly any of them appear to have been the object of careful physiological experiment. The use of garlic in the same disease has also recently been revived. M. Gibier, desirous of ascertaining whether these drugs were of any real value, has submitted them to the test of careful experiments (*Comptes Rendus*), and has found that rats inoculated with the poison, in spite of being fed with a mixture of meat and garlic every day to the extent of 4 grams of garlic per day, succumbed to the disease in ten or thirteen days, even when their systems had been saturated with garlic by feeding on it a month

previous to inoculation. Garlic, therefore, is neither a prophylactic nor an antidote to the poison. The same results followed the trial of hydrochlorate of pilocarpine as a remedy. The cats and rats experimented on died of hydrophobia, and the inoculation of the nervous matter produced the same disease in other subjects of experiment.

The Case of Dr. A. E. Rawson.

IN our last week's issue we referred to the refusal of the Board of Guardians of the Carlow Union to grant superannuation allowance to Dr. Rawson, who, at the early age of 40 years, with a wife and four children dependent upon him, has been permanently disabled by paralysis, caused by a blow on the head from a stone which was thrown during a riot at the last general election. Dr. Rawson's is a truly pitiable story. We are, however, pleased to be enabled to inform our readers that Professor Thorold Rogers, M.P. for Southwark, having had his attention drawn to the subject by his brother, Dr. Joseph Rogers, of the Westminster Union, has given notice of his intention to interrogate Mr. Trevelyan, the Secretary for Ireland, with the view of ascertaining whether the Local Government Board can, under the special circumstances of this case, intervene, so as to reverse the decision of the Carlow Board of Guardians.

The Progress of Cremation.

THE decision of Mr. Justice Stephen in the recent case of cremation of a child by Dr. Price, of Llantrissant, that the disposal of a dead body by this method, if conducted without nuisance to the living, is not in itself an illegal act, has given the Cremation Society of England a *raison d'être*, and created quite a flutter of pleasurable excitement among its upholders. The fear of legal proceedings being now removed, the Society have issued a circular, setting forth that they are ready with freehold ground and apparatus for effecting cremation at Woking, in Surrey; but that as they are aware that the chief practical objection urged against the employment of cremation consists in the opportunity which it offers for removing the traces of poison or other injury which are retained by an undestroyed body, they impose the following restrictions upon relatives or friends of deceased persons:—

I. An application in writing must be made by the friends or executors of the deceased—unless it has been made by the deceased person himself during life—stating that it was the wish of the deceased to be cremated after death.

II. A certificate must be sent in by one qualified medical man at least, who attended the deceased until the time of death, unhesitatingly stating that the cause of death was natural, and what that cause was.

III. If no medical man attended during the illness, an autopsy must be made by a medical officer appointed by the Society, or no cremation can take place.

Retiring Rooms for Men and Women.

At the meeting of the Paddington Vestry on Tuesday (March 4th) Mr. Mark H. Judge, A.R.I.B.A., proposed the following resolution, which was carried by a large majority, viz., "That in the opinion of this Vestry it

is highly desirable that public laboratory accommodation (with w.c.'s, &c.) for both men and women should be provided for the use of every part of the parish, and that a special committee of ten members be appointed to consider and report as to whether this accommodation cannot be provided in such a way as to be a boon to the immediate vicinity in which it is placed, instead of being a nuisance, as must be the case, more or less, where structures for this purpose are erected in the centre of the public thoroughfare." A committee was at once appointed to carry out the resolution.

THE notoriety gained by Dr. Price for cremating his illegitimate child has not altogether subsided. Last week this *soi-disant* Druid appeared at the Llantrissant Police Court, with his housekeeper, Gwenllian Llewellyn, who was fined 35s. for an assault on Constable Francis. While this officer was endeavouring to serve her with a summons for refusing to pay a fine for not registering a child of which Dr. Price was admitted to be the father, she playfully boxed the constable's ears and laid a cane about his shoulders—rather an expensive bit of fun for the doctor.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 20·3 per 1,000 of their aggregate population. The death-rates in the several towns were:—Norwich, Brighton 12; Derby 13; Birkenhead, Bradford 15; Leicester 16; Huddersfield, Hull 17; London, Bolton 19; Edinburgh, Plymouth, Leeds, Portsmouth, Halifax, Salford 20; Birmingham, Blackburn, Cardiff, Sheffield 21; Bristol, Newcastle-on-Tyne 22; Nottingham, Liverpool, Sunderland 23; Preston 24; Dublin, Oldham 25; Wolverhampton 26; Glasgow 27; Manchester 29.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From measles, 3·9 in Portsmouth, and 3·4 in Oldham; from scarlet fever, 2·6 in Preston, 2·4 in Leeds, and 1·7 both in Sheffield and Newcastle-upon-Tyne; and from whooping-cough, 1·2 in Liverpool and in Manchester. The 34 deaths from diphtheria included 12 in London, 3 in Sunderland, 3 in Edinburgh, 2 in Glasgow, 2 in Birmingham, 2 in Preston, and 2 in Leeds. Small-pox caused 8 deaths in London, 6 in Sunderland, 2 in Birmingham, and one each in Liverpool, Glasgow, and Sheffield.

PROFESSOR C. A. CAMERON, of Dublin, has just been elected President of No. 3 Section (Chemistry, Geology, and Meteorology) of the Sanitary Congress for 1884, Vice-President of the Institute of Chemistry of Great Britain and Ireland, and a Honorary Corresponding Member of the Agricultural Research Association. We understand that a bill to incorporate the Institute of Chemistry and to confer certain privileges in reference to examinations on chemistry is about to be introduced into Parliament.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according

to the latest official returns, as follow:—Calcutta 26, Bombay 27, Paris 24, Geneva 28, Brussels 22, Amsterdam 25, Rotterdam 27, The Hague 21, Copenhagen 18, Stockholm 28, Christiania 26, St. Petersburg 38, Berlin 21, Hamburg 23, Dresden 26, Breslau 34, Munich 35, Vienna 28, Prague 35, Trieste 36, Rome 31, Turin 48, Venice 26, Lisbon 36, Brooklyn 17, Philadelphia 22, and Baltimore 21.

DR. CLIFFORD ALLBUTT's first Gulstonian Lecture at the London College of Physicians, on Friday last, on "Visceral Neuroses," was a happy effort, and evoked frequent outbursts of applause. The second and third lectures in continuation will be delivered at same time and place this afternoon and on Friday next. By the courtesy of Dr. Allbutt we are enabled to place Lecture I. before our readers to-day.

THE subject of the "Croonian Lectures" for the present year is "Evolution and Dissolution of the Nervous System." Dr. Hughlings Jackson has been selected as lecturer, and they will be delivered at the London College of Physicians on the afternoons of March 19, 21, and 26, admission, as in the case of the Gulstonian Lectures, being free to members of the profession.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE ADVERTISING OF MEDICAL BOOKS IN THE LAY PAPERS.—A short time ago the London College of Physicians passed a resolution against the advertising of medical books in lay newspapers, a custom which was very prevalent among its Fellows and Members. We are of those who believe that it is completely *ultra vires* of any of the medical corporations to dictate to its Licentiates or Fellows whether he will or will not advertise his books in this manner, and against the advertising of an honestly-written book we cannot see how objection can be taken. To do so would in our opinion be an unwarrantable interference with every man's perfect liberty. There is no calling in which affectation against advertising is carried to a greater extent than in the medical, and none in which it is to a greater extent obliquely resorted to. These remarks are made in view of Messrs. Churchill's list recently, and regularly published in the *Athenæum*, and in which the names of Fellows of the Royal Society and of the College of Physicians figure prominently. We have no earthly objection to the advertising; we wish to know, however, what has become of the resolution of the College of Physicians, and by what principle in ethics it is permitted to these prominent members thus to advertise, while humbler members would be tabooed for doing the selfsame thing? We notice, likewise, that readers of the *Scottsman* are informed by advertisement that Sir Andrew Clark's address on Catheter Fever, delivered at a special meeting of the Edinburgh Medical-Chirurgical Society, will be found in the *Edinburgh Clinical and Pathological Journal* for March 1st. It is difficult to see that this announcement is intended merely for members of the medical profession.

THE GLASGOW HOSPITAL AND DISPENSARY FOR DISEASES OF THE EAR.—In consequence of the indisposition of Dr.

Cassells, a vacancy has occurred in the office of Surgeon to this dispensary, and several candidates are in the field and actively canvassing. Among others we are surprised to learn that Dr. Thomas Barr is a candidate, and on this account, viz., that Dr. Barr is at present Aural Surgeon to the Western Infirmary, Lecturer on Aural Surgery at Anderson's College, and Aural Surgeon to the Sick Children's Hospital. One would have thought that, in all conscience, Dr. Barr's hands must be already pretty full, and that he ought to be contented with the measure of public aural appointments which he holds. We wonder if there is anything else in Glasgow, in the aural department, to which he could possibly aspire. Dr. A. D. Stewart, a talented aural surgeon, Dr. Erskine, and Dr. Downie are also candidates. Dr. Cassells has our entire sympathy in his continued illness, and our best wishes for a speedy convalescence.

DEATH-RATE OF GLASGOW.—For the week ending with Saturday, the 1st inst., the deaths in Glasgow were at the rate of 28 per 1,000, as compared with 25 in the preceding week, and 29, 25, and 27 in the corresponding periods of 1883, 1882, and 1881.

EDINBURGH ROYAL HOSPITAL FOR SICK CHILDREN.—The number of patients treated in this hospital during February was 103. Of these 57 were in the hospital on the 31st January, and 46 were admitted during the month. 30 were discharged from the hospital cured and 8 were relieved. The average daily sick in the hospital during the month was 58. 773 patients were treated at the dispensary, and 11 were vaccinated, making in all 784. Of 403 new cases during the month, 302 were from the city, 79 from Leith, and 22 from the country. Thus the number of patients treated at the hospital during the month was 887.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 1st inst., was 92, and the death-rate 19 per 1,000. Diseases of the chest accounted for 50 deaths, and zymotic causes for 15, of which 2 were due to fever, 4 to scarlatina, and 4 to measles, the intimations of these diseases for the week being 13, 50, and 99.

INFECTIOUS DISEASES IN EDINBURGH.—According to the report of the Medical Officer of Health for the city, submitted to the Town Council's Public Health Committee on the 4th inst., 759 cases of infectious diseases were reported during the month of February—measles, 555; scarlatina, 166; typhoid, 25; diphtheria, 12; typhus, 1. In the New Town 267 of the cases of measles existed, 158 in the Old Town, and 130 in the southern suburbs. Nine of the typhoid cases were in the New Town, 12 in the Old Town, and 4 in the southern suburbs; and the single case of typhus occurred in the Old Town. There were 28 cases in the City Hospital, 60 in the Old Infirmary, and 28 in the Sick Children's Hospital—total, 116. As compared with the total number at 12th February, this shows an increase of 17.

ST. ANDREWS UNIVERSITY MUSEUM.—A large and important addition has lately been made to the St. Andrews University Museum by the acquisition of a number of rare and interesting specimens of marine life from the London Fisheries Exhibition. These have been mounted and arranged meantime in the large hall of the United College by Professors McIntosh and Pettigrew; and on Thursday night last, on the joint invitation of the Principal and Professors of the United College and the Council of the Literary and Philosophical Society, a largely-attended conversation was held in the hall for the purpose of publicly introducing the collection. The specimens were excellently classified, the first section being

devoted to the protozoa or elementary forms of life, and proceeding sectionally to the higher and more complex forms. The crustaceans included many fine specimens from Australia. There was also a beautiful series of dried Indian and Chilian crustaceans, and a complete collection of Indian molluscs, presented by Dr. F. Day, F.L.S., Commissioner for India at the Fisheries Exhibition.

THE MEDICAL BILL.

THE Bill has passed through its two first stages in the Lords without opposition, and stands for committee on the 20th, its principle being now established and its details remaining to be worked out. The Huxley dogma and the "Buccleuch compromise," intended for preserving the free trade in diplomas, were not even heard of in the brief debate, and it may reasonably be assumed that those visionary expedients are dead and buried, and that the principle of a minimum competency test is established. As regards its details, the Bill is admitted on all sides, even by the Government, to need amendment, and the only question which remains to be thought over is as to what these changes must be, to which problem those interested, if they be wise, are now applying themselves. We indicate a few of these alterations in the analysis of the first portion of the Bill which we publish to-day, and we shall have to point out—next week—many other respects in which changes for the better ought to be made; but we do so in no hostile spirit, but rather to contribute to the perfection of the measure, and to make it acceptable to the House of Commons. We are not at one with those who consider it good policy that the profession should "open its mouth and see what the king would send it," and we do not think we are at all the worse friends of the Bill because we offer suggestions to those in charge of it who must necessarily be dependent for hints upon those whose experience of medico-educational matters enables them to hit the blots of the measure.

We are truly gratified that the Bill has got so good a start, and that the determination of Government is manifested to put it through both Houses before any chance of a dissolution arises on the Franchise Bill. On the one hand we hope that the licensing bodies whose interests are involved will show their wisdom by meeting the measure in a conciliatory spirit; on the other, we look for a determined and clamorous support of its principles by the profession at large. If any of the Colleges assume a mulish attitude of anti-reform, so much the worse for them; they will deserve no pity if their interests are overridden; and if the profession at large be lacking in enthusiasm, so much the worse for it: it will only have itself to blame if it has to endure the diploma traffic, free trade in quackery, and the incubus of the General Medical Council for years to come.

If this come to pass it will not be the fault of Government or of Lord Carlingford, who have done their duty against all discouragements. We shall have ourselves alone to blame.

THE FELLOWSHIP OF THE EDINBURGH COLLEGE OF SURGEONS.

THE College has taken, within the past month, a step apparently intended to re-establish the F.R.C.S. Edin. in the public estimation, from which it has fallen in consequence of the free sale of it to all who pleased to pay and could pass muster for respectability. On the 4th of February a code of laws was enacted which will come into operation on the 15th of October next, and which declares that "every candidate, with the exception of those admissible under the old Consti-

tution, shall be required to show that he is twenty-five years of age, and that he has for at least two years subsequent to the date of his licence been engaged in the study or practice of his profession, and shall pass an examination."

So far so good; but the examination does not seem to be a very terrible ordeal. The Licentiates of the College are to answer "on clinical and operative surgery, and one out of six specified optional subjects;" while those not Licentiates of the College have to superadd surgical anatomy. To appreciate to what extent the higher education of the surgeon may be disregarded by a candidate seeking the F.R.C.S.Edin., our readers must be informed that the candidate is expressly permitted to produce no evidence of acquaintance with any five out of the following six subjects:—

- a. Surgery in any one of its ophthalmic, aural, laryngeal, or other special branches;
- b. Advanced anatomy and physiology;
- c. Pathology and morbid anatomy;
- d. Midwifery and gynaecological medicine and surgery;
- e. Medical jurisprudence and hygiene;
- f. Practice of medicine and therapeutics.

Finally, for fear these examinational requirements should prove too severe for the senior candidates for the Fellowship of the College, it is provided that any practitioner of forty years of age may be let in by ballot without being subjected to this trying ordeal. Furthermore, "candidates who do not find it convenient to repair to Edinburgh, may be permitted, by a vote of the College, to be enrolled as Fellows in absence."

In these times, when there is no check save public opinion upon the sale of higher medical or surgical titles, we may be thankful for any little recognition of the principle that a practitioner should not be a Fellow without some other qualification than a money payment; but under the new system for which we hope, we venture to anticipate that the F.R.C.S. will not be conferred without some better qualification than an undefined examination in "clinical and operative surgery." Such a test is obviously a farce.

LIABILITY OF HOSPITAL SURGEONS FOR POST-MORTEM EXAMINATIONS.

We have heard that Dr. Quinlan, of St. Vincent's Hospital, has been threatened with an action at law for having performed the post-mortem examination on a patient who was the subject of an inquest, as recorded in our last issue. We trust Dr. Quinlan will not be induced to buy off this demand, for the point raised is of the highest importance to hospital surgeons generally, and we are confident that Dr. Quinlan will be supported by the opinion of the profession at large. As a question of law it is more than doubtful whether any action lies for the making of a post-mortem examination, because, as we believe, no one has a right of property in a *cadaver*, and no money claim can be made for injured feelings. But if any personal right to recover damages existed, we doubt that such right could be enforced against a surgeon who performed an autopsy in the *bond fide* discharge of his duty, and for scientific or registration purposes. A patient enters an hospital subject to all contingencies which may arise in the case of his or her death, and when it becomes the duty of the surgeon to ascertain the cause of death either for the elucidation of the nature of the disease or for the purpose of giving a true certificate of the cause of death, we do not see how he could be made responsible. If he be not legally answerable, no rule of the hospital administration could make him so, even if he knew

of it, and we will go so far as to say that it is the duty of every hospital surgeon, while giving proper consideration to the wishes of friends when it may be possible to do so, to disregard those wishes and make an autopsy when the obscurity of the disease requires it.

ANALYSIS OF THE MEDICAL BILL.

Read a second time in the House of Lords, March 6th. To be Committed March 20th.

In this Analysis of the Bill all important phrases are printed verbatim.

BE it enacted, &c.

PART I.

ADMISSION TO MEDICAL PRACTICE.

2. The Medical Register shall be continued.
3. A person only, *whether male or female*, who has proved his or her competency in medicine, surgery, and midwifery by passing the final examination shall be entitled to be registered.

Affiliation.—It is expedient, for the purpose of putting the practitioner under control of a licensing body, and in order to provide for the life of these bodies, through whom the future educating and examining systems are to be worked, to require that each State examinee shall take a diploma or degree before he is admitted to registration, for which object it is necessary that the foregoing clause and clause 28, subsec. a, should be amended. The necessity for this "affiliation" of the examinee to his licensing body was recognised by Lord Ripon in 1871, and by the Duke of Richmond in 1873, both of whom amended their bills in this direction. Moreover, all private bills have contained the same "affiliation" provisions. The chief difficulty in the way of the amendment is that women are included in the final examination, but are not admitted by certain Colleges; so that it was found necessary to introduce into the Bill a proviso which declared that if a College should refuse its diploma to any State examinee, the State certificate should in that case be a registrable qualification—a cumbersome, but, we imagine, an indispensable provision.

4. A registered practitioner may "practise the callings of medicine, surgery, and midwifery, or any of said, and may recover any expenses, charges in respect of medicaments or other appliances or any fees to which he may be entitled," Members of Colleges of Physicians exempt.

5. Shall be exempt from serving on all juries and corporate offices.

6. A person shall not be entitled to recover any expenses, charges or fees for any medical or surgical advice or attendance, or for any operation, unless he proves that he is registered.

8. Nobody but a registered practitioner shall hold any appointment—

- (a) In the military or naval services, or
- (b) In any hospital, &c., not supported wholly by voluntary contributions, or in any lunatic asylum, &c., union workhouse, or other public establishment, or
- (c) To any friendly or other society, or
- (d) As a medical officer of health, or
- (e) In any emigrant or other vessel.

Medical Boards.

9. (1.) There shall be established in each part of the United Kingdom a medical board.

- (2.) The numbers of the medical boards shall be—

- (3.) Sixteen chosen for England. Two each by Oxford, Cambridge, and London Universities; one each by Durham and Victoria Universities; four each by the London Colleges of Physicians and Surgeons.

- (4.) Thirteen for Scotland. Three by Edinburgh University; two each by Glasgow and Aberdeen Universities; one each by St. Andrews University, Edinburgh College of Surgeons, and Glasgow Faculty; two by Edinburgh College of Physicians; and one by the College of Surgeons and Glasgow Faculty collectively.

- (5.) Eleven for Ireland. Three each by Dublin and Royal

Universities; two by College of Physicians; three by College of Surgeons.

Representation on Medical Boards.—These have been materially altered since the Bill was first introduced. The London Colleges are given four delegates each, and the Scotch Colleges are allowed five representatives as against eight returned by the Scotch Universities. These are very necessary and just changes. The Irish Board stands as last year, the Dublin College of Physicians being out off with two delegates only. This is not only an injustice to the College, but it imperils the impartiality of the Irish Local Board by giving the two Universities a predominance of voting power to which they have no just title. On the principle by which the English and Scotch Boards are regulated (i.e., the number of delegates given to a body to be proportionate to the educational work done by it) the Irish College of Physicians is certainly entitled to a third representative. This is, moreover, a very serious question, because, inasmuch as the delegates to the Medical Council are to be elected by the Local Board, it is quite possible, and, we fear, by no means unlikely, that the Irish Corporations would find themselves outvoted by the University interest, and thus deprived of any voice in the General Council.

The "Direct Representative" and Crown Nominee.—The clause, as it stands in the Bill, also excludes from each Local Board the direct representative and the Crown nominee for that division of the Kingdom, and thus excludes the profession at large and the Government from a voice in the local administration of the education and examination. By this omission the exclusive power of the licensing bodies, which it is the aim of the Bill to dilute, is perpetuated in the Local Boards, which will thus, as the Medical Council now does, express the interests—not of the profession and the public—but of teachers, lecturers, and licensing bodies. To place the Board in this condition would be a fatal error, especially as the examination and education schemes are to be made by it, and not by the Central Council, and thus the independent members of the Council (so to speak) would be bereft of all influence save that which they might exercise for a few days once a year, in the dog days while the Central Council was sitting. We hope that the profession will insist on the Bill being amended so as to place the direct representatives and Crown nominees for each division of the Kingdom on the Local Boards *ipso facto*.

(6.) A medical board shall be renewed every five years; all its members being eligible for re-election.

The system of re-electing the whole medical board every five years is objectionable, as it would create periodical turmoil, break up the administrative integrity of the board, and put each licensing body in the hands of its representative for so long a period as five years. Rotation would be much better as a method of renewal of the board.

(8.) Any person of full age shall be qualified to be elected a member of a medical board.

(11.) The same person may be a member of more than one board.

This clause would admit non-medical persons to a local board which is to be charged solely with medical functions, a proposal which is objectionable. Considering that the elective function is, in the case of many licensing bodies, almost exclusively in the hands of laymen (e.g., the University of Dublin, in which seven aged clergymen elect), the contingency of having the medical affairs of the country settled by inexperienced laymen would under this clause be by no means remote.

(12.) Privy Council on report of Medical Council may increase the number of authorities entitled to return a member.

(13.) Or may deprive any authority of the privilege.

(14.) And shall every ten years take into consideration the number of members returned by the constituent authorities, and add to, or reduce the number of members.

10. The medical board shall make or change a scheme for—

(1.) The holding of final examinations; and

(2.) The appointment of examiners; and

It will be noted that the divisional board examination is to deal with "final," i.e., practical subjects, the primary or fundamental subjects (such as anatomy, chemistry, and physiology) being left to the licensing bodies. The scope of the final examination might with advantage be more clearly defined, but we believe it will be sufficiently comprehensive to serve as a check upon the primaries.

This proposition is clearly a wise one, inasmuch as it reserves to the educational institutions their function and their reason for existence. Provision for supervision and control of the primary examining bodies by the divisional board will be found at sec. 20, but that provision ought to be strengthened, and no opportunity for laxity permitted.

(3.) The nature and conduct of such examinations, and the qualification of candidates as to age, moral character, and any other matter necessary or expedient to be determined by rules. Provided that—

(b.) Provision shall be made for the admission of women, but such distinctions (if any) may be made as may be judged proper between the cases of men and women, so however that the examinations of men and women shall be in all general respects equal as respects proficiency in medical knowledge and experience.

All schemes shall be framed so as to secure as far as is practicable in each division of the United Kingdom an equality of standard in each final examination and an equal capacity for testing proficiency; also, care shall be taken that the same comparative value shall be assigned to the different branches of knowledge, and for that purpose the same maximum number of marks shall be assigned for the same branch of knowledge throughout the United Kingdom.

This is the only clause introduced into the Bill to ensure that one divisional board shall not underbid those of the sister kingdoms for the patronage of the student. It is altogether insufficient, because it does not order any similarity of the period of study or scope of curriculum accepted by the various boards. The establishment of a standard of competency in the practitioner by means of sufficiently high minimum standard of curriculum, examination, and fee throughout the kingdom, to secure which has always been admitted to be the chief object of medical legislation, was embodied in every Medical Bill from that of Sir James Graham to the present date, whether the measures were promoted by Government or by private members. In the Marquis of Ripon's Bill of 1871 it was provided (sec. 10) that the General Medical Council should frame rules for the purpose, *inter alia*, of "securing the equally strict application of the rules so that a licence under this Act may be granted on like terms throughout the whole of the United Kingdom." Again, in the Duke of Richmond's Bill of 1878 it is declared "expedient to give the General Medical Council powers to ensure" that the qualifying "certificate may be granted on the like terms in all cases," and the General Medical Council is accordingly ordered to "frame . . . rules . . . for regulating the curriculum . . . and the examination . . . and the subjects thereof, and the standard or passing, and the method of conducting the same . . . and it shall be the duty of the Council to see that the examination rules in each part of the kingdom are so framed that the qualifying certificate shall—as nearly as possible—be granted on equal terms so far as regards the curriculum of study, examinations, and standard."

It is almost needless to point out that it would be futile

for one divisional board to proceed to fix upon a sufficient curriculum of study, a comprehensive examination, or an adequate examination fee, if it were obliged to act in apprehension of being underbid in all these respects by a divisional board elsewhere. It is clearly in the public interest—setting aside all medical considerations—that the student shall not be bribed by brevity of study, ease of examination, or cheapness, to run from London or Dublin to Glasgow or Edinburgh.

There is no provision in this Bill against such competition amongst divisional boards, and without it the measure is unsatisfactory.

Medical Council.

13. The Medical Council shall consist of eighteen persons, viz. :—

- Six Crown nominees ;
- Two direct representatives for England ;
- One do. for Scotland ;
- One do. for Ireland ;
- Four elected by the medical board of England ;
- Two, Scotland ; and
- Two Ireland.

This clause abrogates the existing law, which orders that four Crown representatives shall be appointed for England, one for Scotland, and one for Ireland, and thus enables the Privy Council to appoint six Crown representatives of one nationality, a proceeding all the more invidious because the Crown acquires by the Bill a vote of one-third of the whole Council, whereas it at present only possesses a vote of one-fourth.

Any person of full age shall be qualified to be a member of the Medical Council, and may be a member of medical board and also of the Medical Council.

See note to Clause 9, Sub-section 8.

The Medical Council shall be renewed every five years, places being filled up as above set forth.

A casual vacancy occurring amongst the direct representatives shall be filled up by election by the registered medical practitioners. If it occurs during the fourth or fifth year after any quinquennial renewal of the Medical Council, shall not be filled up.

See note to Clause 9, Sub-clause 6.

15. The Medical Council shall visit recognised examinations, and inquire into the sufficiency thereof.

The Medical Council shall have power by order to regulate the performance of their duties by each medical board. Any medical board aggrieved may appeal to the Privy Council.

PART II.

Medical Education.

19. Every candidate for final examination

- (1.) Must have passed a preliminary examination, and
- (2.) been admitted as a medical student, and
- (3.) passed through a prescribed course of medical education, and such medical education shall comprise such experience in the practice of medicine, surgery, midwifery, and the acquisition of such professional and scientific knowledge as may be necessary for the purpose of securing efficiency in his exercise of the profession of medicine, surgery, and midwifery.

20. Each medical board shall make or alter a scheme with respect to the following :—

- (1.) The preliminary examinations, and
 - (2.) The course of medical education.
- In defining the course, the scheme shall describe—
- (a) The schools which are to be considered proper places of education ;
 - (b) The times and places at which examinations are to be held ; and
 - (c) The authorities which are to be considered competent for conducting or for appointing examiners to conduct such examinations, or any medical authority.

A scheme shall be of no validity until it has been approved by the Medical Council.

21. Each medical board shall ascertain by inspection or

otherwise the sufficiency of the education provided by schools, and by visitation or otherwise to inquire as to the examinations held by any recognised examining authority, and to take such steps as may be necessary for depriving any school or any authority of recognition.

The analysis of the portions of the Bill referring to titles, distribution of funds, foreign practitioners, and quacks will be continued in our next.

Correspondence.

THE POSITION OF THE "DIRECT REPRESENTATIVE" UNDER THE MEDICAL BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the Bill has now received its second reading in the Lords, and the necessary amendments will be considered on the 20th inst., I think it right to call the attention of the profession to the humiliating position to which the Bill relegates our elected representatives, in order that immediate steps may be taken to claim for them the influence in medical affairs to which they are entitled.

The Medical Reform Bill has been forced upon the attention of the public and of Parliament by the incessant demands of the profession that they should have some voice in the settlement of their own affairs. That demand was obstructed and made the occasion for sneers at the general practitioner by the majority of the Medical Council and by those who considered themselves placed above sympathising with the claims of the working men of our profession ; but, in spite of this hostility, the point has been carried, and now none—not even the Medical Council—ventures to challenge the clauses of the Bill which decree the election of "direct representatives." But the same influences have been used, and are still being used, to clip the wings of our future delegates, and prevent them exercising due authority in medico-educational affairs.

As the Bill now stands, the scheme of medical education and examination in each division of the Kingdom is to be worked out in all its details—the course of education and standard of examination to be regulated ; the examining bodies to be recognised, and the examiners to be appointed by the local boards ; and the power of the Medical Council is limited to the registering of the decrees of these boards, or suggesting alterations, if necessary.

But these local boards are to be made up exclusively by the licensing bodies, neither the Crown nominee nor the direct representative being admitted to the conclave, and, consequently, neither of the delegates to the Central Council, who are supposed to be independent of pocket interests, are permitted by the Bill any more authority than may be exercised during a few days' meeting of the Central Council once a year, convened to supervise arrangements already decreed by the local board.

This concentration of the power in the hands of the delegates of the licensing bodies is the evil which the Bill is constructed to remedy, and yet it perpetuates it in its worst form.

I appeal, therefore, to you and to the organisations which are entrusted to protect the interests of the profession at large, to exercise all influence to cause each "direct representative" and the Crown nominee to be placed, *ipso facto*, on the local board for his own division of the Kingdom. I have every reason to hope that, if an amendment of the Bill to this effect be forcibly urged, the Government will be willing to accede to it, and I know that the opposition is limited to a few who are interested in reducing to a minimum the power of the general practitioner. I trust you will aid me in counteracting that attempt.

I am, Sir, yours, &c.,

ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
President, Irish Medical Association.

THE HISTORY OF SURGERY AND ANATOMY IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—I am at present engaged in writing a history of the Royal College of Surgeons in Ireland and of the schools of ana-

tomy, surgery, and medicine which have from time to time been established in Ireland. I would feel grateful for any information in reference to the following points:—Titles of works on medicine and surgery published in Ireland previous to the year 1800; information relative to Surgeon White's "School of Anatomy," Ormond Quay, Dublin, which was in existence in 1824; the "Moore Street School of Medicine," in which Dr. John O'Brien delivered a course of lectures on Medicine in 1827; the various dissecting-rooms of Crampton, Wright, and other surgeons, their situation, &c. I should be glad to see old lecture tickets issued before 1840, and to receive any information of interest in connection with the History of Surgery in Ireland.

I am, Sir, yours, &c.,

CHARLES A. CAMERON.

15 Pembroke Road, Dublin.

Royal College of Physicians, Edinburgh.—The following gentlemen have obtained the licence of the Royal College of Physicians, Edinburgh:—

Mallach, A., Barrow-in-Furness.
Ward, J. S., Lisburn, Co. Antrim.
Fall, E. A., London.
Stevens, Arthur P., London.
Hale, George Ernest, London.

Hewson, C. W., Nova Scotia.
Brookless, Edward L., Banbury.
Thomas, George, Manchester.
Luckman, Edward L., Manchester.
Carr, Alfred A., London.

The Medical Society of London.—At a general meeting of this Society held on Monday, March 3rd, the following office-bearers were elected for the current year:—President: Arthur Edward Durham. Vice-Presidents: John Brunton, M.D.; Alfred Cooper; Richard Douglas Powell, M.D.; Sydney Jones. Treasurer: Alfred Wiltshire, M.D. Librarian: William Henry Allchin, M.B., F.R.S.E. Honorary Secretaries: Alfred Pearce Gould, M.S.; James Kingston Fowler, M.D. Secretary for Foreign Correspondence: Sir William MacCormac, D.Sc. Council: Samuel Benton; Thomas Lander Brunton, M.D., F.R.S.; R. Brudenell Carter; Samuel Cartwright; John Cavafy, M.D.; Henry Radcliffe Crocker, M.D.; John Henry Drew; Sir Joseph Fayrer, K.C.S.I., M.D., F.R.S.; Henesage Gibbes, M.D.; F. de Havilland Hall, M.D.; Jonathan Hutchinson, F.R.S.; Edward Lead; Francis Mason; Edmund Owen; Isambard Owen, M.D.; Arthur Ernest Sansom, M.D.; Charles Brodie Sewell, M.D.; Thomas Gilbert-Smith, M.D.; William Heath Strange, M.D.; William Henry White, M.D.

The Cancer Hospital, Brompton.—The annual general meeting of the governors of this Hospital was held at Brompton on Wednesday, the 5th inst., under the presidency of George T. Hertslet, Esq. (Treasurer). From the 33rd annual report of the committee, it appeared that the hospital was progressing satisfactorily, and that, although there had been a falling off in the income from legacies during the year, this was more than compensated in the increased amount received from donations and annual subscriptions. The works in connection with the extension of the building have been completed, and many additional beds are available, and now occupied by patients, which has made it necessary to appoint a clinical dresser and superintendent of nurses. The surgeons' report showed that the number of new patients was 1,245, of these, 408 were admitted to the wards, and 837 treated by other means. The total number of visits made by new and old patients, was 4,173. The report having been adopted, the usual votes of thanks terminated the proceedings.

National Health Society.—The eleventh annual report of the National Health Society, which was read on the 4th inst. at the Society's rooms, 44 Berners Street (Dr. Robert Farquharson, M.P., in the chair), shows that the Society has carried on its work during the past year in a most practical manner. Hundreds of lectures on sanitary subjects have been delivered, not only all over the poorer parts of London, but in provincial towns, to large audiences of working men and women, classes of girls, district visitors, and others engaged in work amongst the poor. The Society is much encouraged by the practical results of their lectures on keeping the house healthy, rearing of infants, prevention of the spread of infectious diseases, preparation of food and kindred subjects, knowledge of which is so much needed in our densely-crowded neighbourhoods. The questions of poisonous dyes in domestic fabrics, of smoke abatement, dust collection, and the prevention of cholera, have been investigated and reported upon by special committees appointed for the purpose. The Health Exhibition held by the Society last June was commented upon, and the Secretary stated that more than one hundred members had joined the Society during the year.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY—Hospital for Women, 2 p.m.—Metropolitan Free, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Orthopaedic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 2 p.m.
TUESDAY—Cancer Hospital, Brompton, 3 p.m.—Guy's 1.30 p.m.—St. Mark's, 9 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 2 p.m.—West London, 8 p.m.
WEDNESDAY—Great Northern, 2 p.m.—London, 2 p.m.—Middlesex, 1 p.m.—National Orthopaedic, 10 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Mary's, 1.30 p.m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.
THURSDAY—Central London Ophthalmic, 1 p.m.—Charing Cross, 2 p.m.—Hospital for Diseases of the Throat 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London, 2.30 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.
FRIDAY—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—King's College, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal South London Ophthalmic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.
SATURDAY—King's College, 1 p.m.—London, 2 p.m.—Royal Free, 9 a.m. and 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

Notices to Correspondents.

MR. NIXON (Shrivenham).—Residents of almshouses are not usually paupers within the meaning of the Act, and cannot, therefore, claim free medical attendance of the parish doctor. With very few exceptions, almshouses are tenanted by indigent persons who are in receipt of a small allowance to keep them above parochial relief. It is only in the rare case where an almshouse is supported out of the parochial rates or funds that an inmate could by law claim gratuitous medical attendance.

DR. J. O. F.—The "Medical Register" for the current year is not yet published.

THE LONDON HOSPITAL.—Once again it is announced that financial difficulties have overtaken the London Hospital, the expenditure of which now exceeds its income by £15,000 per annum. Unless this deficit is in some way made up, no alternative to closing a portion of the institution presents itself, and thus the sole general hospital in East London will be compelled to limit the amount of good it is able to do amongst a teeming population of over one million of people, all more or less poor.

THE SERVICES OF MIDWIVES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel much obliged if you or some of your readers would kindly answer the following questions: What is the experience of dispensary surgeons as to the value of a qualified midwife? What is the usual mode of obtaining one? What are her required qualifications; what are her duties; and who orders her services to a case? What is her tenure of office? What is her ordinary salary? If sent to the country is her travelling expenses paid?

Yours, &c.,

A DISPENSARY SURGEON.

[In country districts especially qualified midwives are a great help to dispensary medical officers, as they relieve them of much trouble and visiting in serious cases of labour, and of all trouble in natural cases. The appointment of district midwife is made by the dispensary committee, with the approval of the board of guardians and Local Government Board; the salary, usually £20 to £30 a year, is fixed by the guardians. Candidates are advertised for. A certificate qualifying to practise midwifery from the College of Physicians, Rotunda or Coombe Lying-in Hospitals, or Maternity of St. P. Dun's Hospital is all that is required, beyond testimonials as to character, &c. Her duties are to attend to cases when called on, and when directed so to do by the medical officer, but her attendance does not relieve the medical officer of any responsibility, unless he is satisfied that the case is one of natural labour and that she is competent to take charge of it. She is bound to send for the medical officer if anything goes wrong. Her tenure of office depends on the will of the dispensary committee, guardians, and Local Government Board. As a candidate for appointment, her travelling expenses would not of course be paid, nor would such expenses of an appointed midwife be paid unless she had an agreement with those appointing her that they should be paid. See General Rules and Regulations for Government of Dispensary Districts, 1832, pp. 100-102, Circular No. 23, dated August 2, 1861.—ED.]

MR. DUNNAN (Cloveley).—We are not aware that Dr. Moffatt's lecture, which was referred to in a recent issue of this journal, has been published; in any case, the theory therein propounded has been entirely upset by previous and subsequent experiments; this fact you will find noted at p. 171 of the current volume of the *Medical Press*.

MR. I. I. (Leeds).—The number is already nearly out of print.

DR. STOKER.—We hope to refer to your apparatus in our next.

DR. C. T.—The occurrence is much to be regretted, but we do not see from the facts before us that the gentleman concerned can be fairly charged with anything more serious than thoughtlessness, and we counsel you to accept his apology, although we agree with you that it is scarcely couched in the language of a man who sincerely regretted an error.

MONTICARLOW.—The Annual Metropolitan Dinner of the Irish Graduates' Association will take place at the Holborn Restaurant on Monday next. Full particulars will be found in our advertisement columns.

MEDICAL CERTIFICATES OF DEATH.

Is a dispensary medical officer obliged by any law or rule to give a medical certificate of death to the Registrar of the same district—the relieving officer being the Registrar.

[Yes. Every medical practitioner is bound to certify to the Registrar under sec. 20 of Births and Deaths Registration Act. See back of certificate form. The penalty for omission is £2.—Ed.]

DR. S. L. W.—Were we to expose the proceedings of every quack to whom our attention is drawn a considerable portion of our space would be thus occupied. The instance of black-mail levying you record differs v no essential respect from the usual course of these pests of society. You can do no good single-handed, and pending legislation it is better to let the matter rest for a time.

NEMO.—The action of Jequrity has been attributed to the presence of the bacilli, which speedily develop in the extract prepared from. Its use in the treatment of granular lids seems to be well established.

MR. SANDERSON.—In all cases where deficiency can be proved there is a remedy; but it would be unwise to seek it unless the grounds on which it is claimed are thoroughly well made out, and clear to everyone interested.

H. R. H.—The gentleman who wrote the article has requested to be allowed to make a personal reply to the communication; and he will, therefore, be glad to know how the information had best be conveyed. The matter is now in his hands.

DR. CLEAVER.—The formula is CHCl_3 .

DR. COUSINS (Portsmouth).—Your communication was crowded out of present number. We hope to find space for it in our next.

MR. SYMONDS.—A treatise on the subject was announced as in the press three months since, but we have not yet heard that it has appeared.

MR. PILKINGTON.—Your communication is better suited to the columns of the *Students' Journal* than to a medical journal which is read chiefly by practitioners of medicine. We hold the MS. at your disposal and will hand it over to the editor of our junior contemporary if desired.

DR. RIDLEY DALE's interesting case of Retroversion with Puerperal Convulsions shall appear in an early number.

Meetings of the Societies.

WEDNESDAY, MARCH 12TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Flower, On the Principal Types of the Human Species.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At 5 p.m., Gulstonian Lecture: Dr. Clifford Allbutt, Chapters on Visceral Neuroses.

ROYAL MICROSCOPICAL SOCIETY.—At 8 p.m., Professor Abbe, On the Distance of Distinct Vision.—Mr. T. E. Rosseter, Further Observations on *Stephanoceros* Eichbornii.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 8 p.m., Dr. George Gulliver, On Etiology and Pathology of Cholera.—7.30, Council Meeting.

HUNTERIAN SOCIETY.—At 7.30 p.m., Council.—3 p.m., Mr. Poland, On a Case of Acute Suppuration of the Hip and Elbow-joints.—Dr. G. H. Savage, Cases on the Borderland of Insanity and their Treatment.

EDINBURGH OBSTETRICAL SOCIETY.—At 8 p.m., Professor Simpson, On a Case of Porro's Operation for Fibroid Tumour of the Uterus.—Dr. Freeland Barbour, On the Anatomy and Relations of the Post-Partum Uterus.

THURSDAY, MARCH 13TH.

ROYAL INSTITUTION.—At 3 p.m., Professor Tyndall, On the Older Electricity.

THE PARKES MUSEUM OF HYGIENE.—At 5 p.m., Dr. Henry Veale, On Organisation and Management of Field Hospitals.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At 8 p.m., Living and Card Specimens.—8.30 p.m., Mr. Hartridge, Tumour of Choroid.—Mr. R. Marcus Gunn, Case of Arterio-Venous Communication on the Retina.—Mr. A. Stanford Morton, Hemorrhage in Region of Macula.—Mr. Adams Frost, An Artificial Eye.—Dr. H. H. Benson: (1) A Case of Coloboma of the Iris; (2) Drawings of Ophthalmic Cases.—Mr. Nettleship: (1) Case showing Blood-vessels in the Vitreous; (2) Lymphatic Nævus of Orbit and Eye; (3) Central Senile Guttate Choroiditis; (4) Central Senile Arterial Choroidal Atrophy; (5) Thickening of Retinal Vessels in a Case of Glaucoma.—Mr. S. Snell, Two Cases of Retinal Glioma, in one of which Shrinking of the Eyeball occurred without Perforation.—Dr. G. A. Brown, A Case of severe Conjunctivitis, with formation of Membrane on the Cornea.—Mr. M'Hardy, Observations which appear to indicate a means of reducing the danger from Malignant Glaucoma while increasing the efficacy of Iridectomy in the Treatment of Chronic Glaucoma.—Mr. G. E. Walker: (1) Acute Glaucoma of four week's duration, with Recovery of good Vision; (2) Sympathetic Ophthalmia, Evulsion of False Membranes and part of Iris; Recovery of good Vision—with living specimens.—Dr. Gowers, On some Cases of Spasm of the Ocular Muscles.—Dr. D. M'Keown, On a means of Diminishing the Blindness from Purulent Ophthalmia in Infancy.—Dr. A. H. Benson, On Jequirity and its value as a Thera-

peutic Agent.—Mr. R. M. Gunn and Dr. J. Anderson, A Case of Nerve Disease with Ocular Symptoms, including alleged Unilateral Diplopia.—Mr. Nettleship: (1) Cases of Recovery from Amaurosis in Infants; (2) Cases of Retro-ocular Neuritis.

FRIDAY, MARCH 14TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At 4 p.m., Professor Flower, On the Principal Types of the Human Species.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At 5 p.m., Gulstonian Lecture: Dr. Clifford Allbutt, Chapters on Visceral Neuroses.

ROYAL INSTITUTION.—At 8 p.m., Mr. J. N. Langley, On Mesmerism.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Dr. S. West, On a Case of Multiple Hepatic Abscesses in a Boy.—Mr. Butlin, On a Case of Foreign Body in the Oesophagus: Oesophagotomy.—Dr. Finlay, On Cases of Enteric Fever associated with Rheumatism.—Mr. Davis Colley, On a Case of Dislocation of the Spine.—Living Specimens: Perforating Ulcer of the Foot, by Mr. Edmund Owen; Dislocation of the Patella, by Mr. Golding-Bird.

ACADEMY OF MEDICINE IN IRELAND (Medical Section).—At 8 p.m., Specimen by Card: Dr. C. J. Nixon, Cirrhosis of the Kidneys and its Effects. Papers: Dr. Wallace Beatty, Urticaria Pigmentosa (patient exhibited).—Dr. McSwiney, Report of a Case of Paralysis in a Child (patient exhibited).—Surgeon-Major Gore, A.M.D., On the Etiology of the Common Climatic Fevers of the Kumaoon Hill ranges.—Dr. C. J. Nixon, Sudden Death in Croupous Pneumonia.

TUESDAY, MARCH 18TH.

STATISTICAL SOCIETY.—At 7.45 p.m., Dr. G. B. Longstaff, The Recent Decline in the English Death Rate, considered in connection with the Causes of Death.

Vacancies.

Bridgnorth Infirmary.—House Surgeon and Secretary. Salary, £150, with rooms, &c. Applications to the Secretary by March 15.

Coombe Hospital, Dublin.—Assistant Master, Applications to Master, or at Coombe Hospital.

Essex and Colchester General Hospital.—Physician. Applications to the Secretary by March 19.

Flintshire Dispensary.—House Surgeon. Salary, £100, with furnished house, &c. Applications to the Secretary by April 15.

Kent Hospital.—Physician on the Staff. Applications to the Secretary at the Hospital, Canterbury, by March 22.

Sussex County Hospital, Brighton.—Assistant Surgeon (honorary) also a House Surgeon, salary, £80, and £10 per annum for each resident pupil. And an Assistant House Surgeon, salary, £40, with board, &c. Applications to the Secretary by March 19.

Appointments.

BUCHAN, W. A., M.B. Edin., House Surgeon to the South Devon Hospital, Plymouth.

DOWNIE, J. W., M.B., Lecturer on Diseases of the Ear and Throat at the Western Medical School, Glasgow.

GIBBS, R., M.B.C.S., Medical Officer for the Teignmouth District of Newton Abbott Union.

MCLELLAND, J., M.D., M.B.C.S., Honorary Physician to the Liverpool Infirmary for Children.

MARSH, J. H., M.B.C.S., Medical Officer for the Hulton District of the Bolton Union.

POWELL, S., M.B., M.R.C.S., Assistant Physician to the Hospital for Epilepsy and Paralysis, Regent's Park.

RYGATE, D. J., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Second District of the Cambridge Union.

SPOKER, E. H. S., M.B., B.Sc. Lond., Medical Superintendent to the new Infirmary, Fulham, S.W.

TURNELL, A. P., M.R.C.S., Medical Officer for the Fourth District of the Cambridge Union.

WOOD, G. B., M.B., C.M. Ed., Resident Medical Officer to the Jersey General Dispensary.

Births.

CASSAN.—March 2, at Gainsboro', the wife of Theodore Cassan, M.B.C.S., of a son.

Deaths.

CHRISTIE.—February 27, at Tunbridge Wells, James Christie, M.D. Aberd., of Gowanlee, Westfield, Dundee.

DEMPSKY.—February 29, suddenly, Meldon Joseph Dempsey, M.D., of Charterhouse Square, London, aged 54.

DOHERTY.—March 7, at his residence, 16 Merrion Square, Dublin, William Izod Doherty, L.D.S., R.C.S.E.

EASTES.—March 2, at his residence, London Street, Folkestone, Silvester Eastes, M.R.C.S., J.P., aged 71.

GREIG.—February 27, at his residence, York Place, Clifton, Bristol, Charles Greig, F.R.C.S.

HART.—February 27, at Springfield Place, Bath, William Hamilton Hart, M.R.C.S., of Poona, India, aged 25.

HOGG.—March 3, at Clebury Mortimer, Shropshire, Henry Lee Hogg, M.R.C.S., and L.S.A., aged 70.

KIDD.—March 4, suddenly, at Killarney Hill, Bray, from disease of the heart, Fanny, the wife of George H. Kidd, M.D.

MADDEN.—February 29, at his residence, Bloomfield Place, Bath, Henry Ridewood Madden, M.D., aged 65.

REMINGTON.—March 2, Thomas Remington, M.D., formerly of Bristol, aged 67.

WALKER.—March 6, at Brierley Hill, Henry Walker, M.D., J.P., aged 64.

A Course of Lectures

Delivered at the London Hospital during February, 1884.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S.,

Emeritus Professor of Clinical Surgery at the London Hospital; Consulting Surgeon to the London Hospital, and to the Royal London Ophthalmic Hospital.

ON DISLOCATIONS AND FRACTURES. (a)

MR. HUTCHINSON announced his intention in this lecture of dealing, in the way of rapid survey, with the general principles involved in the recognition and treatment of dislocations and fractures; and of the first kind of injury he especially insisted on the great importance attaching to their diagnosis by the practitioner. By the commission of errors in this respect, and by failing to appreciate the true nature of an injury involving dislocation of a limb, the surgeon is not unlikely to secure for himself a greater amount of discredit than would follow from almost any mistake that he could make in professional practice. Nor is it difficult to understand the reason for this, since by the permitted existence of dislocation for any considerable length of time, deformities may be set up, and discomfort to the patient thereby produced, which no attempt to cure will succeed in removing; but, as a general rule, all such consequences arise from the carelessness of the practitioner, who never ought, unless guilty of insufficient or incautious examination, to overlook any ordinary case of dislocation. In order, however, to prevent this untoward occurrence, it is well to bear in mind, and to call into use on every occasion, the fact that a dislocation comes under treatment under two safe rules, as follow:—

1. Never examine a patient in these circumstances without stripping him, and making accurate comparison of the two sides of the body; and
2. Should any doubt arise as to the existence of a

dislocation after cursory examination, conducted according to Rule 1, then refuse to be satisfied until the patient has been put under the influence of an anæsthetic, and then, while in this condition, subjected to every available test, with a view to absolute accuracy of diagnosis. Especially should this precaution be observed in the case of young patients, who naturally resist manipulation when awake, and with those also who are unusually sensitive or restive under examination.

In many cases it will occur that, instead of being simple, a dislocation will be complicated by co-existence of fracture along with it, whereby the difficulty connected with its diagnosis will be much increased; and in young children particularly, complications of this nature are very frequently met with, dislocations of a simple character being rare amongst them. In his own experience, Mr. Hutchinson declared he had never met with simple dislocation of the shoulder-joint in a child; but, on the other hand, he had seen numbers in which there had been separation of the upper epiphysis of the humerus, with consequent simulation of dislocation. In the wrist this form of injury does not occur, the hip being by far the most usual site of it; and in the case of children it is important to remember that when symptoms of dislocation are apparent, then they should be taken as affording indication of the occurrence of other injuries as well.

Among young children separation of the epiphysis of the long bones is a common accident, and it is not to be regarded in any way as a fracture either of surgical or anatomical neck. In consequence of the force required to produce complete displacement of the sundere parts being very great, this condition is, as a rule, replaced by one of incomplete displacement, which also the extensive surfaces of the disconnected portions of bone contribute a good deal to bring about,—in the humerus, e.g.—in which, when so injured, a forward sliding of the bone takes place for a little distance; but the combination of this separation of the epiphysis and dislocation of the bone at the joint is one of those accidents which, in Mr. Hutchinson's experience, do not occur.

(a) Abstract of Lecture delivered on Friday, Feb. 15th.

Special risks of danger, even to a fatal termination of the case, attend those examples of separation of the epiphysis in which irregular stripping away of the periosteum from the shaft of the bone occurs, the epiphyseal end adhering, and a periosteal sleeve with muscular attachments being thus loosened from the subjacent bone. Museum specimens of this kind of injury are rare, notwithstanding they are not infrequent; but when produced they rapidly end in death. Suppuration, too, which in fractures of bone rarely occurs, may attend the separation of epiphyses, being in such case due to the separation of the periosteum.

In adults dislocation of both bones of the forearm at the elbow-joint is not uncommon, but among children it is exceedingly so: in this class of patients that form of injury which is described as a dislocation of such nature consists in the clean separation of the epiphysis, which is encouraged at the elbow-joint by the profusion of ossifying centres found in that region, and which when it is seen is usually said to be a dislocation backwards. The amount of displacement produced by such an accident will depend on the position assumed by the bones affected in relation to the joint, and the possibility of the confusing appearances that may be seen ought to be an effectual guard against the issue of a hasty or unwarranted utterance respecting the absence of any fracture. The ease with which displacement of the epiphyses can take place in children is the main reason why so-called dislocations at the elbow-joint are so commonly seen in them; and the factor is found in the low position of the coronoid process, the principal opponent to backward dislocation in young subjects. This process is, indeed, itself practically an epiphysis at this age, being of soft, yielding structure, and being easily broken down.

In treatment of separation of the epiphysis at the elbow in children, the plan most successfully practised is that of fixation on a moulded splint adjusted to the back of the limb, which is to be bent into a position in which the forearm is at right angles to the upper part of the limb. The splint is to extend high up the arm, and in fastening it strapping should be employed, a pad being so adjusted as to bring steady pressure to bear on the lower part of the humerus. All the steps of the operation should be carried out while the patient is completely under the influence of an anæsthetic, the free and invariable use of which was very strongly advocated by the lecturer in these cases. The pressure, moreover, thus applied to the lower end of the humerus must be considerable in order to secure the desired result, and should not be omitted on account of swelling, which in some cases will be found present to some extent, being occasioned by the tearing injury inflicted on the periosteum. In a recent case seen by Mr. Hutchinson neglect of these precautionary details had resulted in ankylosis at the joint, and it is desirable that the practitioner should always be guarded in his prognosis of a recovery without stiffness of the elbow in all such cases. In separation of the lower epiphysis of the radius it is common for a mistaken diagnosis to be made, the injury being under such circumstances assigned as dislocation of the wrist-joint. One of the best examples of the condition so produced is to be found in a preparation at the London Hospital Museum, and it is highly important to recognise the nature of the lesion whenever it occurs. As a rule, there is only an incomplete displacement of the epiphysis, but one case at least is on record in which the part was entirely separated. The disunited parts should be placed in apposition, under an anæsthetic, as a first step towards treatment; and then the limb should be put up in the ordinary way.

In proof of the infrequent occurrence of dislocation of the wrist, Mr. Hutchinson said he had never seen a case himself, and those injuries which were described as such dislocations invariably turned out to be, in the young, separation of the epiphysis, and in the adult, fracture. Likewise, he questioned the existence of so-called sub-glenoid dislocation at the shoulder; and in every case that he had examined with a view to testing the existence

of such a deformity he found it to be one of sub-coracoid dislocation, the certainty of which could be made clear by resort to accurate measurement; by which means the absence of any lengthening of the limb, a condition which must necessarily occur to the extent of one and a-half or two inches in sub-glenoid dislocation, is at once rendered apparent. To Professor Flower is due the credit of drawing attention to the facts here explained, and which imply that what has been called sub-glenoid is in reality sub-coracoid dislocation. Dr. Howe also had, previously to Flower's observations, noticed that lengthening must necessarily follow on sub-glenoid dislocation; but in spite of all the correction the error had received, a well-known manual of surgery continues in its latest edition to perpetuate it, and by means of illustrations depicts the two forms of displacement, showing the limbs as being of equal length in both forms of injury.

Among children displacements of the elbow may be treated with very favourable prospects of obtaining good results; but the case is very different when the patient is advanced in years, for although in them reduction may be completely effected without fracture, still there is ever present danger of subsequent development of chronic rheumatic arthritis in the joint, this being an almost invariable sequel to such cases. Different opinions, however, have been expressed respecting the order in which the two events occur; whether, that is, the dislocation is primary; but the lecturer decidedly averred that there can be no question that such is the fact. In consequence, therefore, of the extreme probability of future occurrence of rheumatic arthritis in the majority of elderly patients who come under treatment for displaced elbow, it is incumbent on the surgeon to speak with the greatest caution when called upon to give promise of a useful limb, the chances of any result of this kind being very small in comparison with the almost certain probability of permanent arthritic mischief setting in.

Fractures are grouped under two heads, viz:

A. Fractures with displacement.

B. Fractures without displacement.

In connection with these injuries it should be remembered that, though occurring in the same bone, and bearing the same distinctive name, as, e.g., Potts' or Colles' fractures, still a very great amount of diversity may be exhibited by them, and it must not be expected that any two examples of the same variety of fracture will be exactly similar in all respects.

As in cases of separation of epiphyses, so in fractures, the nearer the injury is to the joint extremity of the bone the greater probability there will be that displacement of the fragments will only partially ensue. Impaction of the pieces may occur, and as a result it often happens that the favourable position assumed on recovery is due, not to the surgeon's skilful treatment, but to the accidental fixation of the fragments of bone at the time when the injury has been received. For this reason it is advisable to avoid hurry in placing retentive apparatus around the limb under such circumstances, for it is quite possible to set up a great deal of harm by injudicious application of pressure in this way. In his own practice Mr. Hutchinson said he had often treated Colles' fractures at the wrist without employing any kind of splint whatever, and he urged the necessity of carefully considering the needs of every case separately, and then to treat it in accordance with the particular requirements it possesses.

In the majority of cases of Colles' fractures but a small amount of displacement is found to exist, but exceptional instances do occur in which the reverse condition obtains, and such cases present difficulties in the way of treatment. Some years ago Mr. Hutchinson dissected many examples of this form of fracture, and he had come across none in which any great amount of displacement existed, and in some cases, though crepitus could be felt, it was not until the periosteum was removed that actual evidence of displacement could be obtained.

Complete reduction is imperatively requisite when displacement accompanies fracture; and in all such

cases it is very much wiser to bring the patient under the influence of an anæsthetic before commencing to restore its contour to the distorted limb. This proceeding is the more desirable also on account of the absolute safety with which anæsthetics can now be administered; and aided by this means of assistance, the surgeon should not rest contented until his efforts are rewarded by perfect restoration of its lost symmetry to the injured part, except, of course, in cases where an extreme degree of impaction renders any such occurrence impossible.

Once the fragments have been restored to their proper place, however, there is no tendency in them to resume the vicious position assumed as a result of fracture; and hence necessity for confining the limb in a splint apparatus will not exist. This method of treatment will be demanded in a certain number of instances, being those which form exceptions to the general rule just laid down; but Mr. Hutchinson considers that quite 4-5ths of the fractures of limbs can be most satisfactorily treated without applying any splint whatever, the harm caused by which through pressure far exceeds the benefit conferred. Whenever they are employed, the simpler the kind of splint that is used the better will be the result, the straight form being the best possible, admitting of free extension, and being also easily retained in place. Fourteen days should, Mr. Hutchinson urged, be the maximum time during which, if it must be applied, a splint should be allowed to remain, as otherwise there arises much danger of rheumatic stiffening of the joint.

As a commentary on the fatuity of inventing complicated splints and apparatus for fixing fractured limbs, none of which have ever received general approval, the lecturer referred to an ingenious instrument devised by Dr. Gordon, of Belfast, after long-continued anatomical study of Colles' fractures. This, which was intended for general use among surgeons, is figured, said Mr. Hutchinson, in a text-book by a leading surgeon, *upside down*; and assuming from this that even the author of the work is practically unacquainted with the splint, although he writes about it, what chance is there of its ever being universally adopted?

Not only Colles', but all fractures, are most successfully treated by extension, which can readily be applied through the agency of the simple straight splint. Very thick pads should be fitted to the splint, and in ordering from instrument makers it is necessary to insist on this especially, particularly with regard to splints for treatment of fractured femur. Finally, on this subject of splints, Mr. Hutchinson declared that he had seen many more instances of bad union follow the use of modern improved apparatus than ever were witnessed under the old plan of treatment of fractures by the straight splint.

Fractures of the neck of the femur occur in a great variety of forms, and it is an unfortunate conventionality which divides them into extra- and intra-capsular fractures, as though the bone was always broken straight across either in or outside the capsule of the joint. As a matter of fact, examination of numerous specimens showed this to be an occurrence of great rarity, and the varieties assumed are very considerable. Thus the great trochanter may be broken across, or both trochanters, and the fracture itself may be partly without the capsule. When great deformity exists, however, the existence of extra-capsular fracture may be suspected, and on grasping both hips if there is found greater thickness on the injured side it may be taken as certain that the fracture is at any rate not entirely in the capsule. In all cases of this class of fracture, whether so-called extra- or intra-capsular, union by bone should be the surgeon's principal aim; and such a result may, in Mr. Hutchinson's opinion, be expected.

SMALL-POX has for many months past been virtually absent in a fatal form from London, and at the meeting of the Asylums Board on Saturday last it was reported that there had been but six deaths during the present month, 78 had been discharged cured, and that but few cases were now under treatment.

The Gulstonian Lectures

FOR 1884.

Delivered at the Royal College of Physicians, London,
March 7th, 12th, and 14th.

By T. CLIFFORD ALLBUTT, M.D. Cantab., F.R.C.P. Lond.,
F.R.S.,

Senior Physician to the Leeds General Infirmary; Consulting Physician
to the Leeds Hospital for Women and to the Fever Hospital.

LECTURE I.—CHAPTERS ON VISCERAL NEUROSES.—

(Continued).

THAT which I have illustrated by the examples of the stomach may be likewise illustrated by examples taken from the other viscera. Jaundice may be set up simply and directly by causes acting upon the nervous system, or it may be due to local causes only. Or, again, it may owe its origin to some admixture of the two sets of causes. So, again, in the functions of the intestines, either constipation on the one hand, or diarrhoea on the other, may be due to nervous causes acting alone, to local causes acting alone, or to local changes reinforced by nervous reactions. I will only refer in this connection to one more organ out of many—to the uterus and its appendages. How intimately this organ, or this system, is associated with the nervous system is well known, but, unfortunately, the weight of our knowledge all leans one way—it leans to a curious and busy search for every local ill which may arise in the female pelvis, while blind oblivion scatters the poppy over every outer evil, which in its turn may hurt the uterus—nay, more, a resolute prejudice would deny that, in the woman, any distress can arise which owes not its origin to these mischievous parts. "*L'utérus c'est la femme*" is a proverb which has received a new development in these days; for, if by courtesy, rather than by conviction, women be granted the possession of a few subsidiary organs, these, at best, have no prerogative nor any order of their own.

The uterus has its maladies of local causation, its maladies of nervous causation, and its maladies of mixed causation, as other organs have; and to assume, as is constantly assumed, that all uterine neuroses, or even all general neuroses in women, are due to coarse changes in the womb itself, is as dull as to suppose that the stomach can never be the seat of pain except it be the seat of some local affection, or that the face can never be the seat of *tic douloureux* unless there be decayed teeth in the jaw. All mucous membranes, indeed, seem readily to betray nervous suffering by relaxation or changed secretion; and I make no doubt whatever that a very large number of uterine disorders which are elevated to the place and name of diseases of the uterine system, are but manifestations of neurosis. All neuroses are commoner in women than in men. Facial neuralgia is commoner in them, migraine is commoner; so is gastralgia, again, and the pseudo-angina. Not only so, but in the uterus, they possess one organ the more, with its own rich nervous connections, and its own chapter of added neuroses; but to say that all these maladies are due primarily to uterine vagaries is to talk wide of all analogy. Again, some men as brave as others feel equal sums of pain far more acutely than the others; women, speaking generally, feel pain more than men do; patient as they are, they seem to have less reserve of force, and less resistance, more susceptibility and resentment, and less capacity. Yet there is no standard of pain, nor of men, by which you shall say this patient is a coward, and his outcry exaggerated. Men and women are variously organised in respect of resistance to pain, and their fortitude or their despair must be tested, not by their cries, but by the other features of their characters. What right have we to say that a man writhing in the pangs of a toothache is a great sufferer while, in the same breath, we hint that a woman complaining of a pain in the abdomen is hysterical? The pain is equally invi-

sible, equally unmeasured in the two cases, and the degree of credit to be given to the complaint is to be gauged by other probabilities.

A neuralgic woman seems thus to be peculiarly unfortunate. However bitter and repeated may be her visceral neuralgias, she is either told she is hysterical, or that it is all uterus. In the first case, she is comparatively fortunate, for she is only alighted; in the second case, she is entangled in the net of the gynecologist, who finds her uterus, like her nose, is a little on one side, or, again, like that organ, is running a little, or it is as flabby as her biceps, so that the unhappy viscous is impaled upon a stem, or perched upon a prop, or is painted with carbolic acid every week in the year, except during the long vacation when the gynecologist is grouse-shooting, or salmon-catching, or leading the fashion in the upper Engadine. Her mind thus fastened to a more or less nasty mystery, becomes newly apprehensive and physically introspective, and the morbid chains are riveted more strongly than ever. Arraign the uterus, and you fix in the woman the arrow of hypochondria, it may be for life.

Now, gentlemen, it is time we complete our reaction from this gynecological tyranny, and that we of this College no longer permit ourselves to be snubbed by these brethren of ours, who calmly tell us, with their superior airs, that our use of such expressions as uterine neuralgia, irritable uterus, ovarian neuralgia, neurasthenia, and the like, comes of a shallow sciolism, and is grounded upon the emptiness of our knowledge of uterine diagnosis.

The spirit of meekness alone restrains me from throwing the same stone again, and accusing our gynecological friends of ignorance of neuropathies and of the neurotic diathesis. That no man limited by the bounds of human intelligence can have a fine knowledge of medicine, surgery, and obstetrics is true, is as true of obstetricians as of physicians, but every man can have, and must have, a good all-round knowledge of a kind which will enable him to take the main bearings of any case which may come to him.

For my own part, no conventions arrest me when my opinion is asked by a sufferer. The speculum and the uterine sound were invented as much for my benefit as for other people, and I feel it both my duty and goodwill to examine into every detail of a case, whether medical, surgical or pelvic.

This done, I am able to judge under whose care a patient may best be placed, and the more I thus incidentally learn of surgery and gynecology the more gladly and intelligently I recognise the extensive and dexterous attainments of those of my colleagues who work in those departments, and who can deal with such cases far better than I can. But, I repeat, and repeat again, that the main lines of the diagnosis of any malady whatsoever should be within the province and abilities of any medical man whatsoever. What should we think of a family practitioner who made no diagnosis of a case of acute pneumonia, because his work lay chiefly with mothers, because he had not a stethoscope, and because he intended to call in a physician. On these grounds, I say that any well-educated physician who does his duty to his cases, who does not idly turn them over to specialists, and who is armed with proper instruments of research, should know, as well as another, the main bearings of all his cases, and should claim to be heard on the diagnosis, although he may not and cannot pretend to distinguish minor differences, nor to have complete mastery of all the more refined devices of modern therapeutics. We physicians have been a feeble folk in this, we have shrugged our shoulders and submitted to gynecological taunts in a way that may be very modest, but in a way that betrays our trust and our art. If the gynecologists pelt us with stories of long pain and sickness uncured by medical futilities, but rapidly cured under uterine medication, we can mate their stories, and check them by double the number of cases received by the physician from the sofa, the manipulations and mental abuse-

ments of narrow uterine specialism. To underrate our debt to gynecologists, to forget the great work they have done in the past half century, were as foolish as ungracious; but, like all great movements in special fields of inquiry, it must be subject to reaction, and its results must be checked by those which have been obtained by other methods and in other directions. The wisest and most disinterested of gynecologists now know well how lamentable have been the exaggerations, how narrow the views, and how deceptive the data of many opinions which have passed current in their school, and they are ready to declare that if medicine is not wholly to reclaim a great part of the field occupied by them, its culture must at any rate be shared with the physician. The physician has been at least as much to blame, in that he has contemptuously thrown aside many cases of genuine malady and of genuine suffering as hysteria. Even hysteria is a complaint to be treated and relieved, but the central blunder has been the stupid confusion between the hysteric and the neurotic subject. On adding up the cases in my chamber notebook for the year 1883, I find that under the three heads of neuralgia, neurosis and neurasthenia, 151 new cases were entered in that one year. What a tale of misery does this limited experience of mine indicate! Add together all the patients of all the doctors in the West Riding alone and compute the manifold suffering. Yet I do not hesitate to say, that in our vigorous northern people, hysteria is far from a like extension. On the contrary, if the word be used with due care, I would go so far as to say it is rare.

I remember but one case of hysterio-epilepsy in the Leeds Infirmary in the last year or two, no cases of contracture, and of other hysterical affections but a few, and these often paraplegics, who relapse, and, returning twice or thrice to our care, swell the apparent numbers in our books. Take a hysterical person, man or woman, in its common and, so far, proper sense; take it to mean a person of feeble purpose, of limited reason, of foolish impulses, of wanton humours, of irregular or depraved appetites, of indefinite and inconsistent complaints, seeing things as they are not, often fat and lazy, always selfish; or, to take it in less degree, one capricious, listless, wistful, attractive perhaps, yet having always the chief notes of hysteria—selfishness and feebleness of purpose; and if such persons complain of globus, of palpitation which is never perceived by the stethoscope, of sleeplessness of which the nurse has no record, of dyspepsia which does not lessen the labours of the cook, of pains which never flush the cheek; and, if such person have, or have had, anæsthesia, unreal epilepsy, unreal syncope, unreal palsy, unreal cramps, then set down such person as hysterical, but forget not, nevertheless, to cure her mind and body. Such a patient is, no doubt, a member, a degenerate member, of the neurotic family; but it is almost with indignation that I repudiate the application of her adjective to the nervous sufferer, whom we may call the neuralgic member of that group. Why, gentlemen, my neurotic patients, if I can indicate them by a name, are almost the best people in this wicked world. Rarely endowed with the capacity, endurance, and profounder imagination, of the greatest, they form a large number of those in the second rank who are the salt of society. Let us suppose that Mr. Galton had photographed four hundred of these, inside and outside: the resulting ideal neurotic might be much as follows.

His entry into your room tells of him at once. He enters with a brisk step, and a quick observant eye. You see a slightly built, meagre man; of sallow complexion, or, if coloured, with the colour painted high upon the cheek-bone, the cheeks and the temples are hollow, the temporal arteries being visible under the lean skin, which often shows tanned markings deepened during attacks of pain; the hair is straight, fine, and sparse upon the scalp; the features are sharp, often prominent, the lips thin and the skin dry; with it may be some dry remnants of eczema about the ears or chin. The tongue is protruded and retired quickly, and is generally narrow and pointed; it is rarely indented, and its tip, even when the health is best, does

not cease to be red. There is often a light silvery coating upon the dorsum and mid-line. The bodily frame is lightly and often finely built, the bony fingers and wrists and the visible sinews and radials betraying the absence of fat. Here and there, in later life, a knotty knuckle may tell of gouty parentage. The pulse, when most tranquil, usually ranges between 70 and 80, and accelerates on the least excitement. The clavicles and ribs, in like manner, are prominent, and the heart's apex may be seen to beat sharply before the eye. Its systole to the ear is likewise short and sharp, and the second sound very audible over a wide area. The limbs are small, but often very sinewy; such persons are as active as birds, and the absence of fat in their muscles often gives to these, in states of health, the quality of hardness under the hand. Their conversation, again, is lively and voluble, often keen and brilliant, but impressions able rather than imaginative. Usually, such a patient does not readily come to you; he is brought, half reluctant, by his wife or friend; he says, apologetically, he is an old dyspeptic, and you can do him no good. He has visited all the springs and half the doctors in Europe, and he lays a bundle of old prescriptions upon your desk. Once agate, however, his story will be a long and minute one, but never mauding, wandering, nor whining. His companions will tell you that he is subject to great fluctuations of the animal spirits—gay, even fascinating, in society, brisk, orderly, and thorough in business, but at home dejected or fretful. He is a small eater, a light sleeper, and a worn worker. These persons are the heirs of every true neurosis, from insanity to toothache; and, on the whole, when we consider the infinite perturbations of intermarriage, it is surprising how true they run, or how clearly you may detect the neurotic strain in mixed descendants. Of their visceral neuroses, I shall have to speak hereafter, and would only say now that in both sexes of them migraine, stomach ache, and windy colic are frequent and eminent, and receive the name of dyspepsia; and in the women are added to these uterine and ovarian neuralgias and hyperæsthesias. To call these suffering women of the neurotic type hysterical is to confuse all the due acceptance of names, and, what is worse still, it is to confuse the real relations of things. The neurotic woman is sensitive, zealous, managing, self-forgetful, wearing herself for others; the hysteric, whether languid or impulsive, is purposeless, introspective, and selfish. In the one is defect of endurance, but in the other defect of the higher gifts and dominion of mind.

Now if we turn our eyes upon the flock of women who lie under the wand of the gynecologist, we shall find it so largely composed of the neurotic and hysteric, that we may say in our haste the uterus has no substantial diseases; that its affections are all neurotic, or so far reinforced by neurosis as to depend for their cure mainly upon neuropathic medicine. Herein we in our turn should be to blame. Many a woman, otherwise robust enough, and many a woman, whose weakness may lie not in her nervous system, suffers from uterine disorder, from painful uterine states, nay even from distant sympathetic pains also, which comes of mischief wholly local, or of mischief reinforced by diathesis other than the neurotic. Making, however, the utmost allowance for all these, I contend that a vast number, I will go further, and say a preponderating number, of such sufferers, lie under the scourge of neurosis, and that their uterine and ovarian disorders are either wholly neurotic, or, as I have said, so reinforced by neurosis as to depend chiefly or wholly upon general medicine.

Let me take as an instance a young lady coming of a family in which great mental gifts had thrown into relief the many eccentricities and humours which accompanied them; a family, too, of which no household had been free from nervous disease. She possessed the gifts and the attractions of the neurotic diathesis, and laboured under its defects. It is possible also that she was in some degree under the stress of what Anstie called the unconscious sexual impulse. She was restless, excitable, and suffering. Her pains were mostly pelvic and abdominal.

She never put her feet to the ground, partly because it intensified her pain, partly because she had been forbidden to do so. She had lain on her back for months. Pessaries had often been introduced, but, being intolerable to her, were withdrawn. Her periods were agonisingly painful for the first two days, and were profuse, and she had constant leucorrhœa. Her appetite was almost gone, her stomach queasy, her frame emaciated; but she was unselfish, full of courage, and would have scorned the wiles and exacting whims of hysteria. Her womb had been incessantly under specular and other examinations for a year or two, and, like nearly all such patients, she had uterus on the brain. I found the vagina tender, and the womb exquisitely tender; its substance was soft, and its attachments lax. Its position, therefore, was somewhat backwards and downwards. Acute suffering was caused in the upper hypogastrium when the fundus of the uterus was pressed upon *per rectum*. The rectum was full of fœces. By the speculum, I noted that there was both uterine and vaginal catarrh, and that the os uteri was excoriated—in the state, that is, of the upper lip of a scrofulous and snivelling little boy.

My most difficult task was to win my patient over to the belief that her disease was not mainly uterine, but mainly neuralgic; this once accomplished, our progress though slow was sure. I declined to initiate any treatment whatever until she would get her feet to the ground, and thenceforth cautiously regain the use of her legs. This took three months. Meanwhile, I declined to "cure the ulceration of the womb" for the twentieth time, but made her content with rectal and vaginal astringent douches, first hot and afterwards cold. As soon as she could walk, we perched her upon horseback. She was treated with the phosphide and valerianate of zinc, with bromide of ammonium, iron, quinine, and like remedies, with occasional sedative suppositories. In six months, I found the uterus more compact, the ligaments braced, and the os clean and sound; the leucorrhœa had ceased, and all the parts could be handled without pain. Menstruation was still painful, but less so than formerly, and there was some menorrhagia. She was mixing, however, in general society, could ride gently to hounds, had regained appetite and looks; and, although I then lost sight of her, I have every reason to suppose she is as well as she is ever likely to become.

Now, gentlemen, is not this case one of those which in their degrees could be multiplied a hundredfold from our case-books or our memories, and yet these are they which form a great part of the women who are caged up in London back drawing-rooms and visited almost daily for uterine disease, their brave and active spirits broken under a false belief in the presence of a secret and overmastering local malady, and the best years of their lives honoured only by a distressful victory over pain.

The case I have described was selected by me because it was not one of mere irritable uterus without apparent disorder. Irritable uterus is a genuine malady in spite of the denial given to it in high places. It corresponds to the hyperæsthesia of the stomach which is found in the same diathesis, and which often simulates ulcer of the stomach.

But I pass over all these as neurotic enough, and I assert that, in such neurotic subjects, uterine laxities, moderate displacements, and catarrhs, owe their continuance, and often their very initiation to an atonic state of body, and to a special instability of nerve-endowment which may show itself in local trophic changes, and in perverted secretions. Such changes or such settlements of perverted action are often, no doubt, called to this spot or the other by some local deviation from the normal, as a consumption may take its beginning from some trivial and forgotten catarrh; but the essence of the malady is not there, and to try to cure such a malady by local means is as wise as to try to cure a syphilis by antiseptic dressing of its ulcers.

Such subsidiary means are often needed, often indeed

necessary; but in cases like those under discussion should be used as little as possible, because of the tendency of such methods to arouse and perpetuate a morbid possession of mind in the woman. All this our more robust, more clear-sighted, and more candid gynecologists know well enough; in the rest, the fault may lie rather with modern fashion than with themselves.

Looking only to the uterine organs, their reason bounded by the confines of the pelvis, they attempt to stem the tides of general and diathetic maladies with little Partington-mops of cotton-wool on the ends of little sticks. That many of the cases we have discussed need a judicious combination of local with general treatment is true, but in most of them the patient and the doctor are fascinated by the local phenomena, while nature herself is performing on a far larger scale. If we are to cure disease, we must be able to fly with her and to run with her, as well as to creep with her. In my later chapters, I shall recall the truth which should be ever before us—that the fundamental difficulty in all neurotics, not hysterics, is their nutrition. More fresh air, without expenditure of the slender store of strength, the permeation of their starved tissues with the fat which they themselves so often loathe in their food—these two reforms accomplished, all their organs will take on a more generous and a more vigorous life, all their tissues will brace and cleanse themselves from a purer and richer fountain of blood, and force will be stored up and energy developed, wherein before was dilapidation and sterility. As a shrewd old Yorkshire doctor once said to me: "It's no use, my lad, putting the hands right upon the clock-face if you haven't cleaned the works."

Gentlemen, we are all one-sided; I speak to-day from my own one-sidedness, and my convictions are upon the side of cleaning and repairing the works. Sometimes, no doubt, when the general state of the health is restored, some local trouble set up originally by the constitutional state—be it gout, scrofula, or what not—smoulders on, forgotten, as it were, after the general malady is cured. For such local trouble diathetic treatment no longer avails; it must be wiped out by some local alterative. But, on the other hand, to contend daily with local troubles which daily are regenerated by some vicious habit of the whole system, is to roll up daily the shameless stone of Sisypheus.

STATE CONTROL FOR CHRONIC INEBRIATES. (a)

By H. C. TWEEDY, M.D. Dub.,

Diplomate in State Medicine: Physician to Steeven's Hospital;
Fellow of the Academy.

We live in an age of paradox. Strange that a country that vaunts of a heritage of freedom—freedom of thought, word, and action—should be held in thralldom by those very laws which it has enacted for the preservation of its own liberty; but of the many social anomalies which abound, none is more conspicuous than that which permits the harmony of domestic life to be imperilled, the substance of families to be wantonly squandered, and the moral tone of society to be threatened by unhappy beings who, themselves the slaves of a degrading and all-powerful passion, are enabled with comparative impunity to impose troubles without end upon others, because, forsooth, the "liberty of the subject must not be interfered with."

The fallacy under which such a system of oppression is possible has long been recognised.

John Stuart Mill, in his work on "Liberty," has the following passage:—"As soon as any part of a person's conduct affects prejudicially the interests of others, society has jurisdiction over it; and the question, whether the general welfare will or will not be promoted by interfering with it becomes open to discussion."

(a) A Paper read before the Public Health Sub-Section of the Academy of Medicine in Ireland, February 14th, 1884.

This fairly enough applies to the question of "State Control for Chronic Inebriates," which, when seriously brought under the notice of the public some five-and-twenty years ago, found at first few advocates, but which, under the healthy influence of fair and impartial discussion, has gained importance in public estimation. At the present time so strongly impressed is a large proportion of the community that more stringent measures are needed, both with a view to the permanent cure of habitual drunkards, as well as for the protection of those who are sufferers through their instrumentality, that we may confidently hope to see at no distant day, in more extended legislation, that full measure of justice of which the Act of 1879 offers but an instalment.

But before entering into details of what has been done and what we conceive ought to be done in this direction, it will be necessary to say a few words regarding the individuals, for whom such legislative control is demanded—in other words, what class of persons may be considered as included in the category of chronic inebriates.

In some cases there seems to be a hereditary propensity to intemperance. In others it shows itself as the manifestation of a disordered nervous system, resulting, it may be, from mechanical injury, or from disease of the brain itself, or again appearing as the result of nervous shock or some wasting bodily ailment, perhaps most frequently of all it appears as the result of a persistent and vicious abuse of stimulants. Be the cause, however, what it may, there are now-a-days many supporters of the belief that such a condition constitutes a form of insanity, quite as real and quite as formidable as any other species of monomania.

Let us take for example an ordinary typical case of so-called dipsomania. We find in the patient an utter absence of power in the will to control the impulses of the senses. We find a complete disregard of the dictates of duty—self-interest. He appears to have no sense of any moral obligation to himself or to others. He is uninfluenced by any feeling of honour, self-respect, or natural affection. He is absolutely regardless of truth, and breaks without hesitation the most solemn promises; and also, which is noteworthy, exhibits in a remarkable degree the most artful cunning and ingenuity in obtaining the means of gratifying an overwhelming and unreasoning craving for alcoholic stimulants.

Can such a person be regarded as sane? Surely a calm and dispassionate consideration of the subject must force upon us the conviction, that the man who, unable to follow the dictates of reason, becomes reduced to a condition which cannot be distinguished from insanity, should become amenable to the laws affecting lunatics, and under proper restrictions should be deprived of that liberty of which he has proved himself incapable of making a worthy use.

Many objections have been raised to this proposition, some of them specious enough, but all capable of being fully answered. That most relied upon by its opponents is the statement that compulsory measures would involve an unwarrantable interference with the liberties of the subject.

This argument, now worn threadbare, may by this time be fairly set aside, so often has it been refuted, and therefore but little shall be said regarding it. The question, however, may in all justice be asked, whether it is not a greater infringement of this liberty, that one individual should be permitted to trespass upon the rights and privileges of many upon whom, of necessity, the chronic inebriate brings trouble and disgrace. Sacred as are the rights of individuals, they are but secondary in importance to the peace and well being of the community. Self-destruction is a crime in the eye of the law, and he who attempts it is justly liable to punishment; but the question has yet to be answered, why the slowness or rapidity of the process should enter as factors in estimating the magnitude of the offence;

or, in other words, why there should be summary jurisdiction for the suicide who attempts by one decisive act to put an end to his existence, while the chronic inebriate can with equal certainty and with the utmost obtrusiveness shorten his days without becoming amenable to any legislative power. There is a grim joke in Robertson's well-known comedy, which never fails to secure the plaudits of our educated fellow-countrymen. When Mr. Eccles is asked whether, on the receipt of a certain annuity, he could manage to drink himself to death, say, within a year; he replies with much alacrity, "I don't know, I'm sure, Sir, but I'll do my best."

This is a fair illustration of the levity with which this mode of self destruction is popularly regarded.

Another plea advanced by those adverse to state control is this: that facilities would thus be afforded to unprincipled persons who might wish, from sinister motives, to put a troublesome relative out of the way. The answer to this is simply, that the same objection is applicable to the law for the confinement of lunatics, and it would be practically impossible that any proceeding of so infamous a character could take place with the sanction and connivance of a magistrate and two medical men of known integrity, who must concur in pronouncing the patient "a fit person to be confined," before any order for his detention could be issued.

Two further difficulties were suggested by Mr. Cross, the Home Secretary, in reply to a deputation which waited on him in 1875, relative to this subject. These were:—1st. The great numbers that would probably have to be taken in charge; and 2ndly. The question of expense.

The former of these objections is sufficiently met by proposing to deal only with the class of persons defined by Mr. Dalrymple as being "dangerous to themselves or others, or incapable of managing their affairs."

In answer to the second objection, it may be urged, in the first place, that many, if not most, of those for whom state control would be desirable are to be found among the wealthier classes, and could readily pay more or less for their maintenance and treatment; while, for those who are not so circumstanced, a plan which has been pursued with much success in America could be adopted—that, instead of allowing the patients to remain idle in the institutions where they were confined, they should be employed at some remunerative labour, the proceeds of which, after paying for the cost of their maintenance, &c., should be handed over towards the support of their families, or should be funded for their own use, and handed over to them on leaving.

Let us now take a glance at the history of this question, and notice the slow but sure progress in public estimation that has marked its course. From first to last we may fairly concede to Scotland the foremost place in ventilating the subject, as well as in achieving whatever legislative success has been attained up to the present time.

In 1855, before the Scottish Lunacy Commission, special prominence was given to the consideration of the best means of dealing with insane drunkards; so also in the report of the Commissioners published in 1857; and the question was favourably discussed in the leading journals of the period. In the same year a paper on the "Medico-legal Relations of the Habit of Intemperance," by Sir Robert Christison, tended to keep up the interest which had been excited. This was followed up by a paper on the subject by Dr. Peddie, in the Medico-Chirurgical Society of Edinburgh, and by numerous able contributions in medical and literary journals. And in 1869, in a paper of very great power, Dr. Symonde brought the matter under the consideration of the Health Department of the Social Science Congress, at the annual meeting held that year at Bristol. Little has been written or said since which has not had its foreshadowings in that admirable paper. Shortly after this Mr. Donald Dalrymple, the member for Bath, encouraged by statements as to the successful treatment

of inebriates in America, brought in, in 1870, his first Bill "to Amend the Law of Lunacy, and to provide for the Management of Habitual Drunkards." This Bill not meeting with success, he then visited the institutions of Canada and the United States to get an insight into their method of working, and so form an idea of the success likely to attend the establishment of similar institutions in this country. Satisfied with what he saw, he brought the subject before the House of Commons in 1872, with the result that a Select Committee of Inquiry was appointed. A vast amount of evidence was taken, and in the report which was handed in in June, 1872, it was stated—

"That there exists an entire concurrence of all the witnesses in the absolute inadequacy of existing laws to check drunkenness, whether casual or constant—that 'it is in evidence that a large proportion of the criminals passing through our gaols attributed their fall to drink. One witness having stated the amount as equal to 75 per cent. in one particular gaol,' and that 'about 20 per cent. of the insanity in Great Britain is placed to the same cause'—that 'there is a very large amount of drunkenness among all classes and both sexes, which never becomes public, and, that without further legislation it must go unchecked.'"

The report of this Committee formed the basis of the well-known "Dalrymple Bill of 1872," and as future enactments must, we believe, draw largely from its provisions, it may not be out of place on this occasion to give a brief *résumé* of its contents.

It defines as an "habitual drunkard"—1. One who in consequence of the habitual intemperate drinking of intoxicating liquor is dangerous to himself or others, or incapable of managing himself or his affairs; or, 2. Is three times within six months convicted in a Court of Summary Jurisdiction of some offence or offences of the definition whereof drunkenness forms part, for which purpose a Court of Summary Jurisdiction may take judicial notice of previous convictions in the same court, or allow the same to be shown by such evidence as to the court seems sufficient. And it provides that "an habitual drunkard may be received as a patient for treatment into a private house. 1. On their own request in writing; or 2. On the request in writing of a guardian of his person, appointed as in this Act provided, and not otherwise.

"An habitual drunkard, being convicted as an offender, as aforesaid, may be received as a patient for treatment in a certified Industrial Hospital on the order of a Court of Summary Jurisdiction, made as in this Act provided and not otherwise.

"No house shall be licensed at the same time both for the reception of habitual drunkards and for the reception of lunatics."

The asylums must be licensed, and will be visited by two magistrates and a medical man annually appointed as visitors, twice at least in each quarter of the year. Patients received into a licensed house at their own request may be detained by compulsion for the time mentioned in their application.

Persons received at the request of others may be detained for periods not definitely specified. The application for the detention of such a person must be made to the Court of Chancery, which may appoint a guardian of the person being a habitual drunkard, who shall have like powers and authority as the committee of the person of a lunatic made so by inquisition. The guardian shall also have power to request the reception of the ward into a licensed house. The Court will appoint a manager to the estate of the patient.

Persons convicted as habitual drunkards by magistrates, under the second definition, are to be sent to a certified industrial hospital, in which such persons only are to be lodged, clothed, fed, and treated, and which will be inspected by a government inspector as well as also by the visitors to the licensed houses. The sentence of detention to be for a period of not less than three,

nor more than twelve months; and the manager of the hospital may after two months permit the habitual drunkard to live with any respectable person willing to receive and take charge of him. If the patient forfeit his license by misconduct he will have to serve his full time in the hospital. If a patient refuses to conform to the rules of the hospital he may be imprisoned for twenty-one days, and will then have to return to serve his original term of detention. Persons inducing patients to escape, or harbouring them, are liable to a penalty of £10, or else three months' imprisonment without fine. Managers or servants of hospitals ill-treating patients, or permitting them the use of liquors or drugs, are liable, beyond other punishment to which existing laws render them liable, to a penalty of £25.

Such are the main provisions of the Bill, which was not read a second time, owing to political changes which took place the same year. It, however, attracted much attention, and became the subject of an animated debate at the Social Science Congress held in 1873.

In July, 1875, a most influential deputation waited, as we have mentioned before, on Mr. Cross, Secretary of State for the Home Department, urging upon the Government the "desirability of introducing in the next Session of Parliament a measure founded on the recommendation of the Select Committee of the House of Commons, for the control and management of a class of persons known as habitual drunkards or dipsomaniacs; but notwithstanding the earnest and forcible advocacy of the petition by the veteran Sir Thomas Watson, the deputation was politely dismissed with a few specious suggestions of difficulties to be overcome, and the result was *nil*.

In August, the same year, the subject excited much attention at the annual meeting of the British Medical Association in Edinburgh. Two very valuable and exhaustive papers on the subject were contributed by Dr. Peddie and Dr. Boddington, and the following resolution was carried by acclamation:—"That excessive intemperance is in many cases a special form of insanity which requires special treatment, with a view, first, to the recovery of those affected; secondly, to the protection and advantage of them and of society. That in the present state of the law such treatment is not attainable, and that it is desirable that legal provision should be made to render it attainable."

In the following year the question was again ably handled at the Social Science Congress by Dr. Alfred Carpenter; and in the subsequent discussion a part was taken by Dr. Cameron, the member for Glasgow, to whom the country owes the Habitual Drunkards Act of 1879, which is in force, is force it can be called, at the present time.

Dr. Cameron's Act, as originally framed, was sound in principle and vigorous in design, combining, as it did, the necessary powers for detention with the permissive character which it still retains; but now, shorn of its compulsory clauses, like the play of *Hamlet* with the part of *Hamlet* left out, it can only be regarded as an indication that the current of public opinion has begun to flow in the direction we would wish; and thus we can accept it as an instalment of more effective legislation in the future. The last words are used advisedly; for as it stands at present, no statute could be more inert. A more adverse criticism on an Act than the three official reports already published by the Inspector of Retreats it would be difficult to find.

The first report was published on the 29th July, 1881, and contained a record of the operation of the Act up to December 31st, 1880. Up to that date only two retreats had been established, and these for male patients exclusively, one being licensed for four patients, and the other for ten patients. During the year 1880, fifteen patients were admitted to the two establishments, five patients were discharged, ten patients remaining under treatment on the 31st December. The Inspector adds (July 1, 1881):—"In the hope of being able to give a

more encouraging account of the number of retreats licensed under the Act, and to gain a little more time for observation upon those which existed, I have ventured to delay submitting my report to you; but I regret to say that, up to the present time, so far from any fresh applications for licenses being made, one even of the two retreats now reported upon has ceased to exist since April last, in consequence of the licensee having decided not to seek a renewal of his license."

The second report is dated July 1, 1882. As a set-off against the closure of one of the two retreats, another was opened for the accommodation of five male and five female patients. During the year ending December 31, 1881, twelve patients, all males, were admitted to the two retreats and fourteen were discharged, four remaining under treatment at the end of the year (four patients at Sheepshead having been discharged by a magistrate on the closing of that institution).

The third annual report, bearing the date July 1, 1883, shows a slight improvement in numbers. Into the two retreats twenty-five patients were admitted, and fifteen discharged, leaving fourteen inmates under treatment on the 31st December, 1881.

It will thus be seen that only three retreats have been licensed since the passing of the Act, and that of these three one has been closed. It is likewise noteworthy that the total number of patients admitted to the retreats during three years amounted in all to fifty-two for the United Kingdom. These numbers speak for themselves. In his first report Mr. Hoffman states that the weekly payments in the retreats ranged from three to four guineas for each patient.

Anyone who reads the Habitual Drunkards Act of 1879 must see that the main cause of its failure is its purely permissive character. The drunkard must, in every case, take the initiative in providing for his own detention. Now, those who are acquainted with the habits of such persons must be aware that one of their leading characteristics is vacillation. They may be perfectly ready one day to sign away their liberty and enter a retreat, and the next day they are as likely as not to give an obstinate refusal; and as certain legal forms have to be gone through, and the machinery of the law moves slowly, the dipsomaniac is exceedingly unlikely to remain in a docile frame of mind sufficiently long for his detention to be accomplished.

Another weak point in the Act seems to be this—that in it there seems to be no provision for the treatment of pauper patients. At the Westminster Police Court, shortly after the passing of the Act, a woman named Jane Elliott was brought before the presiding magistrate as a habitual drunkard. She applied to be placed in a retreat, but the magistrate had no jurisdiction in the matter, as no funds were forthcoming.

Several boards of Poor-law guardians who were applied to with reference to the same difficulty replied that their duty was to provide for the relief of the poor, but not for their moral improvement. Up to the opening of the Dalrymple Home for Inebriates, where the terms are £1 11s. 6d. per week upwards, and an entrance fee of £1 1s., the Act was apparently only intended for persons who were able to pay, as Mr. Hoffmann states, the prohibitive tariff of three to four guineas per week.

Again, the fact that the Act is limited to a period of ten years must act as an effectual barrier to private enterprise. Few, except the most philanthropic, or else the most speculative, individuals would care to hazard their capital on so precarious a venture. The only persons who could safely do so were those who might expect to derive a profit from other sources as well; for example, the proprietors of lunatic asylums, who are, to my mind, unwisely and unfairly excluded by the Act from having inebriate retreats attached to their establishments, the objections usually brought forward being—1st, that the constant association with lunatics might be injurious to dipsomaniac patients; 2ndly, that a stigma might attach to those known to have been confined in asylums for the

insane; and 3rdly, that the inmates of lunatic asylums, not being necessarily teetotalers, and total abstinence being a necessary condition to be observed in the treatment of dipsomaniacs, these latter might be exposed to a temptation from which it would be desirable they should be protected. In answer to the first objection it may be stated, as is known to anyone who has frequently visited well-managed asylums, that cases of an aggravated nature, or such as would be likely to cause injury or annoyance to others, are kept separate from the rest, and that the majority of the patients under control are perfectly harmless, and in many instances are persons of culture and refinement, who may be insane upon some one point only. Besides, it would be quite possible to have the inebriate retreat separate from the rest of the establishment, were there a sufficient number of patients of the inebriate class to warrant the additional expense. The second objection is readily answered thus: that there is no necessity for any publicity, as both duty and self interest would insure the silence of the certifying medical men and the proprietor of the asylum; and it would be only through the indiscreet utterances of friends that any information could be gleaned by the curious as to the whereabouts of the patient. And with regard to the third objection, without entering into the question of the desirability of supplying lunatics with stimulants not ordered medicinally, it might be suggested that stimulants should not appear habitually on the table at meal-times, or else, as was stated in answer to the first objection, that a separate portion of the establishment should be reserved for dipsomaniacs only.

That retreats for chronic inebriates exclusively would be most desirable no one can deny. There are two such at present, which seem to be working in a fairly satisfactory manner, and these two have not their full number of inmates; but should the scope of the present Act be extended by the addition of compulsory clauses, it would be found in a very short time that the demand far exceeded the supply, and a block would inevitably occur, unless the utilisation of existing institutions were at least provisionally permitted. In fact there does not seem to have been any necessity for special legislation on the subject, an intelligent public being quite competent to decide for themselves regarding such matters of detail.

Of course, it goes without saying, that in the case of pauper dipsomaniacs the Government asylums would be for some time the only available retreats, as dipsomaniacs, not being criminals, could not legitimately be sent to prison. There are one or two points which must be touched upon in conclusion.

The question is often asked, How can you draw an exact line between drunkenness as a vice, and drunkenness where it merges into disease or insanity? The best answer that can be given to this is to quote from the words of Sir Robert Christison, who, in reply to a similar question, said that he was always very cautious about giving definitions. He was once asked in a witness-box to give a definition of insanity. He knew very well that this was but the introduction to a dexterous cross-examination, and he replied that that was a problem on which twelve judges in England had tried their ingenuity and failed; that many men had written on the subject and failed; that, therefore, it was not to be expected that he should succeed; but that if counsel would bring a case before him, and he should not only satisfy himself, but satisfy his questioner, whether it was a case of insanity or not. The point is one which must invariably require skilled evidence, and any shrewd and well-educated physician should be equal to the occasion.

There are two other points at issue, both of which in a great measure hinge upon a third point. These three points are:—1. The question of cure. 2. The question of the time occupied in treatment. 3. The provisions in a Bill most likely to affect both these questions.

That chronic inebriates may in many cases be cured there can be little doubt, as was clearly maintained by Sir Thomas Watson, when addressing Mr. Cross on the subject, in 1875. He then said, "that if such persons can be strictly debarred from all access to alcoholic drinks, they will surely, though slowly, recover from this form of mania." This is abundantly proved by statistics. In Mr. Hoffmann's report for 1882, before alluded to, we read in Clause 5, "the results of treatment have been, on the whole, satisfactory."

From the detailed returns made to me by the two licensees, I find that in one case three out of the five patients admitted during the year received decided benefit, and in the other cases nine out of the twenty are spoken of as "certain or probable cures;" and in a recently published Report of the Fort Hamilton Home, near New York, furnished to the Legislature of the State of New York, we learn that, out of six hundred cases treated in that institution, there were one hundred cases under treatment, and five hundred discharged. Of this five hundred, the history of two hundred and eighty-three was known. Of these two hundred and eighty-three, about one-half were improved, twenty-six per cent. relapsed, and seven per cent. had either died or were in hospitals or lunatic asylums.

As regards the time necessary for the requisite treatment, most of those who can speak with authority agree in saying that it is useless to detain a patient for less than twelve months, but that a longer period is desirable, and that the earlier the patients can be brought under treatment the greater will be the prospect of success; and this brings us to our last point, viz., the provisions in a future Bill which would be likely to further both these objects.

In America over ninety per cent. of those admitted to inebriate retreats are volunteers. The reason of this is, that those who are refractory can be compelled to go under treatment, and that by voluntary submission to treatment all publicity is avoided. The knowledge of this power of compulsion in *terrorem* exercises a most salutary effect, and without it the tentative system would be useless. In France, when it is deemed desirable to take proceedings in regard to such persons, the members of the family meet together, constituting what is called a *conseil de famille*, and is presided over by a judge. This body has power to prevent an individual from recklessly wasting his property, and, if violent, of placing him in an asylum. A hint might be taken from this in framing future legislation in this country.

No Bill can be expected to be successful which shall not be partly permissive and partly compulsory—permissive in allowing those who are anxious to be cured to place themselves voluntarily under the control, without which cure is impossible; and compulsory for those who are not willing to be so restrained.

An habitual drunkard might then be restrained—1. On his own request in writing (as in Act of 1879); 2. On the joint certificate of—(a) his nearest of kin, (b) a magistrate, (c) two medical men who should previously have examined him separately, and who should be selected by the relative and magistrate aforesaid; 3. On having been three times within six months convicted in a court of summary jurisdiction of some offence or offences whereof drunkenness forms part (*vide* Dalrymple Bill, 1872, secs. 7 & 9).

The effect of the first two clauses would be the avoidance of all unnecessary exposure, and that of the last two to secure for the patient that early treatment without which a permanent cure has been found to be a practical impossibility. There can be little doubt that the success of such a system would be marked, and that an Act framed on these or similar lines would be found a lasting blessing to the whole community.

Clinical Records.

BALTINGLASS UNION HOSPITAL.

Amputation of Leg for Malignant Ulcer.

By F. V. MACDOWELL, L.R.C.S.I.,

Medical Officer, Baltinglass District and Union Hospital.

J. B., army pensioner, æt. 61, suffering from an epithelial ulcer of leg, was admitted under my care into Baltinglass Union Hospital on 2nd June, 1882. He moved about on crutches, and it was observed that he carried his right leg flexed up and bent at the knee. On examination a prominent ulcer was observed on the front and inner side of right leg, occupying a circumference of about four inches. The diseased surface presented the cauliflower excrescence peculiar to epithelial cancer. The man had a haggard look of suffering, some years previously his leg had been crushed by a wheel, but as no external wound was produced he continued to discharge his duty. A few months after receipt of the injury his attention was directed to the leg by feeling a prominence on the shin bone a few inches above the ankle. The swelling increased, accompanied by pain and loss of sleep, for the relief of which he was sent to Chelsea Hospital from whence he was returned home "unfit," with a pension, and he remained in his own district for some time before coming to me.

The ulcer (which was of a most loathsome nature) had an irregular appearance and was bathed in dark sanious pus, beneath which a vascular net-work was visible. On pressure being used with a probe the tibia could be felt on the inner side, roughened and bare of periosteum. The ulcer was surrounded by a dense epithelial margin but the absorbents and glands in its neighbourhood were free from any contamination; the surface was very irritable and bled on the slightest touch, and no doubt the irritating nature of the discharge, with infrequent dressings favoured the development of the growth. I placed him on a tonic treatment, with the usual astringent lotions, and tried this for one month without any marked change resulting. About this time I took my usual holiday when the case was taken up by my substitute. On my return I considered that amputation of the limb offered the only chance (and a poor one it seemed) of saving the patient's life. An obstacle now presented itself, which it was feared would greatly interfere with union at the stump, as owing to the pain which he felt on placing his foot on the ground, he had latterly acquired the habit of moving about on his crutches with the diseased limb flexed at the knee. This resulted in an angle being formed at the knee-joint with permanent contraction of the hamstring tendons, which even under the anæsthetic it was found impossible to remove.

On 15th August, ether being administered by my friend Dr. Weldon, of Rathvilly, by means of "Ormsby's Inhaler," which acted in the most efficient and rapid manner, I proceeded to operate in the following way:—

Esmarch's bandage was applied from the knee upwards, and the femoral artery secured by a tourniquet, the popliteal being inaccessible owing to the deformity. The flap method was adopted, the incision being made one inch below the tubercle of the tibia, and the vessels secured with carbolic catgut, which was also used in closing the flaps of the stump. I may truly say the operation was almost bloodless, carbolic oil was unsparingly used, and the stump when dressed was allowed to resume the old angle and maintained in that position with bandages. It is unnecessary to give the daily details of this case, the man made a good recovery, leaving hospital three months after operation with a pin leg.

It is now 18 months since this patient was operated upon, and he has not had the slightest symptom of any return of the disease, and is quite well.

Two causes *ce'lebres* in which medical men appear prominently are just now before the law courts. Dr. L. S. Forbes Winslow is sued by Mrs. Weldon for damages for false imprisonment, and as she has subpoenaed nearly 100 witnesses, including her Majesty's judges, divines, and doctors, it is likely to be a prolonged one. In the other case Dr. Page, of Solihull, near Birmingham, brings an action for slander against the husband of a patient, who alleges improper intercourse with his wife.

ACADEMY OF MEDICINE IN IRELAND.

SUB-SECTION OF PUBLIC HEALTH.

A MEETING of the Sub-Section of Public Health was held on Thursday evening, February 14th, at the College of Physicians, the REGISTRAR-GENERAL of IRELAND, President of the Sub-Section, in the chair.

Dr. DUFFEY acted as Secretary in the absence of Dr. Woodhouse.

THE PRESIDENTIAL ADDRESS.

The PRESIDENT delivered an address reviewing the Parliamentary work of the past year conversant with public health and social questions, and giving his views on pending measures of a kindred nature.

On the motion of Dr. CAMERON, seconded by Dr. J. W. MOORE, a vote of thanks to the President for his address was passed by acclamation.

Dr. H. C. TWEEDY read a paper on

STATE CONTROL FOR CHRONIC INEBRIATES,

which will be found on page 250.

Dr. DUFFEY said nobody was more cognisant of the defects of the Act referred to than the member for Glasgow himself who had introduced it in the House of Commons. Unfortunately in its passage through the House of Lords it had been considerably emasculated. The real defect in the Act was its limitation to ten years, for it would be absurd to suppose anyone would spend money in starting an institution on the probability of the measure being renewed by Parliament. That was why Dr. Cameron and others had started the Dairymple Home. If the "Homes" could be placed under the same management as existing institutions for lunatics they would probably be sufficiently numerous throughout the Kingdom.

Dr. HENRY KENNEDY remarked that in the results reported from America he did not hear of any cases that were really cured, and he invited explanation as to whether or not there had been any absolute cures after a year's confinement. The association of inebriates with the inmates of a general lunatic asylum would have a prejudicial effect, as people would not go into a place where there were lunatics. Medical men in practice knew that the number addicted to drink was exceedingly great, and it was lamentable to see persons likely to be benefited allowed to follow their own vicious instincts. He had known men recover, but in no case a woman who had fallen into the degrading vice. The subject of their treatment was, however, surrounded with considerable difficulty.

Dr. CAMERON agreed that every facility should be given for the reclamation of the habitual drunkard, but there had been a little exaggeration of the results of habitual drinking. Dr. Tweedy had represented one authority as stating that 75 per cent. of the crime committed by the prisoners in a certain gaol was due to intemperance. No doubt it often happened that drunkards are thieves and robbers and murderers, but it was simply a coincidence that a man who was a robber, a burglar, or a murderer should also be a drunkard. That 75 per cent. of the persons committed to prison drank was highly probable, but it was equally probable that 75 per cent. of the persons not committed to prison drank too. Were it not so how could the public houses be kept? With regard to the numerous plans proposed for the cure of intemperance he did not think the voluntary system would have the desired result.

The PRESIDENT in confirmation of Dr. Duffey's remarks said the most important provisions of the Bill were destroyed, some, no doubt, in the House of Commons, but the principal in the House of Lords, and its failure was mainly due to the limited period of its operation. As pointed out nobody would put money into a concern that would last only ten years. The great success of some of the institutions in America was due to the fact that compulsory and voluntary seclusion was combined. Those who did not choose to go in ran the chance of being put in by their people. As a member of the Commission on Prison Dietaries he visited a great number of prisons in Ireland, and he was astonished at the number of persons confined for crimes which had been produced directly or indirectly by drink. Touching the question of compulsory confinement for drunken habits,

he saw in a gaol in the north of Ireland a woman who was in for the 235th time merely for drunkenness. She was a "bail prisoner," that is, imprisoned in default of finding bail for good behaviour. Instead of imposing the smaller penalties involved in a conviction for drunkenness, this was the side-wind adopted by the Belfast magistrates for keeping drunkards under control. The woman in question was a lunatic, and ought to be treated as such. She herself said she was sure to get drunk when she went out, and her great desire was to stay in prison. Though not under a sentence compelling her to work, she worked as a matter of taste, and kept herself neat and tidy. It was an outrageous state of the law that she should be treated as a criminal when she was really a lunatic. Having given an example of a dipsomaniac in the upper ranks of life, he said unless means were taken to deal with the disease the number of dipsomaniacs would steadily increase, believing, as he did, in hereditary dipsomania.

Dr. TWENTY, in reply, said he had not alluded to the voluntary system as a defect, but he meant to convey that the voluntary system unbacked by any system of compulsion was a radical defect in the Act. Of course the limitation of the operation of the Act to ten years was a great objection. It was desirable to have retreats for dipsomaniacs, and he advocated the utilisation of lunatic asylums on the principle of using existing means until better were provided. Dr. Kennedy had rightly concluded that the number of cures in America was inconsiderable. In his own experience of individuals with this form of insanity he saw no permanent cure, except where very early treatment was adopted, but there was no means of keeping dipsomaniacs under control for a proper period. Even supposing they were not perfectly cured it would be important to get dipsomaniacs into an establishment where they would be improved. He agreed with Dr. Cameron that the individuals included in the 75 per cent. were guilty of a great number of other crimes besides drunkenness. In reference to the retreat at Kent and the surreptitious introduction there of drink Mr. Hoffman, in his second report, in 1881, had mentioned that public houses in the vicinity of retreats did not cease to give serious trouble to licensees whose establishments were without grounds to confine the inmates within bounds, or where they had not a trustworthy staff to prevent the introduction of drink.

The Sub-Section then adjourned.

OBSTETRICAL SOCIETY OF EDINBURGH.

WEDNESDAY, MARCH 12TH, 1884.

Dr. WILSON in the Chair.

PORRO'S OPERATION FOR A FIBROID TUMOUR OF THE UTERUS.

Dr. BARBOUR exhibited the tumour removed by Professor Simpson.

Professor SIMPSON then read the following account of the case in which he had performed Porro's operation for fibroid tumour of the uterus. The patient in a former case had after a somewhat tedious and lingering labour been delivered without instrumental assistance. The child was, however, stillborn. In the present instance she was being attended by one of the students attached to the Maternity Hospital, who had called in the assistance of the house-surgeon as the case presented some curious points of difficulty. He in turn sought the advice of Professor Simpson, who on visiting the patient found her in a most wretched condition in one of the poorest parts of the town. The patient being anaesthetised and an examination made, a hard body like the head of a child was felt nearly filling the pelvis, and on passing the hand further up the unbroken bag of membranes could be distinctly felt, containing what might be the head of a twin. During her present pregnancy she had suffered greatly from incontinence of urine. She had not been conscious of any abdominal swelling before gestation set in, about the commencement of which she appeared ignorant. Labour pains had set in on the afternoon of the previous day, when she was attended as before stated by a student. On inspection the abdomen was seen to present a quite peculiar appearance. The uterine tumour projected far in front of and close to the lower part of the ensiform cartilage, closely invested by the thin abdominal walls, which were tensely stretched over it. The uterine tumour was nearly in the middle line diverting

but slightly to the right side. Just below the umbilicus there was a depression in the abdominal wall between the uterine projection and a mass which bulged above the symphysis pubis, and occupying the hypogastric and left inguinal regions. It reminded one of an over distended bladder. On palpation the uterus was felt to be almost continuously contracted with occasional access of fuller contractions. A ridge corresponding to Band's furrow was traceable. The lower projection was felt to be solid and continuous with the uterine tumour. Auscultation recognised the foetal heart sounds already somewhat low and feeble, though quite distinct. There was also a hard chancre on the right pudendal labium. The inguinal and pelvic cavities were occupied by a portion of the tumour which blocked up the brim, and was diagnosed to be a fibroid tumour growing from the lower segment of the uterus extending between the layers of the left broad ligament to the side of the pelvis. The partially expanded os uteri could be reached up at the pelvic brim to the right sacro-iliac synchondrosis, the membranes still unbroken. It was clear that the only chance for the woman and her infant lay in an early laparotomy. She was ordered an injection of morphia, and preparations were made for her removal to the hospital. Considerable difficulty was experienced in persuading the patient to come to the hospital, but by the aid of a priest she was at length prevailed upon to enter the hospital, but not till much valuable time had been lost and her chance of recovery very much diminished. When she was at last brought to the hospital, she was in a much exhausted condition, and on examination it was found that the foetal heart had ceased to beat. Drs. Moir, Halliday Croom, and Angus Macdonald all agreed that the only chance for the woman lay in gastrotomy. The abdominal walls, genitals, and vaginal canal having been carefully cleansed and doused with 1 in 2,000 solution of corrosive sublimate, the bladder was emptied and the urine found to be albuminous. The abdomen was opened by an incision, entering two inches above the umbilicus to within two inches of the symphysis pubis, sufficiently long to allow of the protrusion of the unopened uterus. A loop of strong cord was carried round the uterus, as far down toward the cervix as the tumour at its lowest segment admitted of and below the head of the child. The edges of the abdominal wound were kept closely adapted at the back of tumour, whilst by an incision through the anterior part of the fundus and upper part of the body of the uterus, I reached the cavity and easily extracted the infant by seizing the exposed breach. There was very little hæmorrhage, and the turbid contents of the amnion escaped over the abdominal walls. Lawson Tait's clamp was now applied in the site of constricting cord, round the broad ligaments and lower part of the uterus, and the uterine tumour was cut off above. The section on the right side passed outside the right ovary and lower part of the body of the uterus, towards the left side it stopped close to the left Fallopian tube and cut through the left ovary. No fluid had escaped into the peritoneal sac. The long wound was brought together by a series of silk sutures, and the bulk of the tumour, just within the abdominal walls, rendered the adaptation of the edges of the wound close to the stump, which was brought through the lower part of it. The stump and the wound were fully dusted with a powder of equal parts of iodoform and bismuth, and bismuth gauze was applied to the abdomen and bound with a flannel bandage. The patient ultimately died. In some further remarks on the case, Dr. Simpson regretted the fatal result of his case, but said that there was hope in the fact that the mortality from this operation was gradually diminishing.

As a corollary to the above case, Dr. ARNOT, of Bombay, read the accounts of

THREE FATAL CASES OF CÆSARIAN SECTION PERFORMED IN INDIA.

The children were, however, saved. Dr. Arnot made some further remarks on the prevalence of osteomalacia among the Mahomedan immigrants as compared with the Hindoo and Parsee population. Race being an element in the prevalence of the disease.

Dr. CROOM found some difficulty in expressing an opinion on Dr. ARNOT's cases. He, however, preferred Porro's operation to the old Cæsarean section, as it unsexed the woman, and prevented any further trouble.

Dr. BERRY HART suggested that the shortness of the pedicle left had something to do with the fatal result of Dr. Simpson's case. He admitted that the case was unfavourable. He had seen three cases of Porro's and one of Cæsarean section, all fatal.

Dr. UNDERHILL made some remarks on suturing the uterus with metallic sutures, and said that no trouble resulted.

Dr. PETER YOUNG remarked that in Dr. Simpson's case the fibroid tumour had been left when the uterus had been removed, and this might have helped the fatal result.

Dr. BARBOUR remarked that a great difficulty of the case was that of drainage, and was an element of danger to the patient.

Dr. SIMPSON stated, in reply, that, had he not considered the woman, he would have performed Cæsarean section. The case was unfavourable, as labour had proceeded for some time. He also referred to Müller's modification as to the length of the external wound, and drawing the uterus through the wound. Müller's operation has given good results, especially if the liquor amnii be absent. He also replied to Dr. Hart's objection, and showed that the position of the tumour prevented a long stump. After some remarks on Dr. Arnot's cases, he held that suture of the uterus was necessary, especially after the manner suggested by Sanger.

Dr. BARBOUR then read a paper on

THE ANATOMY AND RELATIONS OF THE UTERUS AFTER LABOUR.

The paper was illustrated by some most carefully-prepared specimens, by diagrams, and microscopic preparations.

Special Articles.

PHYSICAL ENDURANCE UNDER TOTAL ABSTINENCE PRINCIPLES.

NEVER, in the history of the Temperance movement, has the value of abstinence from alcoholic or other artificial aids been so signally demonstrated as during the past four months, when, without any preliminary training, the pedestrian Weston has, for one hundred successive days (excluding Sundays and Christmas Day) walked fifty miles a day, until, on Saturday evening last, he completed the number—5,000—which he had undertaken to accomplish in the time specified. Feats of strength and skill have indeed been performed by abstainers and others—feats requiring great force of muscle and steadiness of nerve—some, too, involving great powers of endurance; but all pale into absolute insignificance by the side of the splendid effort just brought to so triumphant a termination. The ancients were wont to point to the pyramids of Egypt, the Ephesian temple of Diana, the mausoleum of Artemisia, the walls and hanging gardens of Babylon, the Colossus at Rhodes, the watch-tower at Alexandria, and the statue of Jupiter Olympus as the seven wonders of the world; and surely we, in our day, may offer to those who talk of the physical degeneracy of the human race this unique example of the contrary—an example worthy to be chronicled as an *additional* "world wonder."

The accomplishment of Weston's undertaking has proved to what capacity for *sustained endurance* the human frame, allowed by temperance in all things, and by abstinence from alcohol in particular, to attain its maximum of development, may be brought. It is not as if, according to the capability of the hour, seventy or any other number of miles were covered in one day and the remainder in another, but the steady effort of walking just fifty miles a day, accomplished with the regularity as it were of clock-work, that is so remarkable.

Fair weather or foul, in sunshine or rain, in tempest or in calm, under every possible form of sky in our ever-varying climate, morning after morning, Weston sallied forth, accompanied by an officer of the Royal Navy and a representative of the press, both mounted on bicycles, and completed his fifty miles (sometimes more, but never less), now

on the public road and now in a prepared enclosure, and, at the close of each day's work, delivered, with unabated energy, an address of twenty minutes' duration on temperance!

During the final week, when the walking took place in London, at the Victoria Coffee Palace, a complete and exhaustive series of observations were made by Dr. Edwin C. Green, a very promising young medical officer, who has just been appointed house-surgeon to the Derby Infirmary, delegated by the Medical Temperance Association for that purpose. The sphygmograph, clinical thermometer, dynamometer, and spirometer were all made to contribute their valuable revelations. The food and excreta were weighed, as was Weston himself—his height being taken before and after each day's walk. The urine, in view to the amount of urea, phosphates, &c., being estimated, was sent daily to that accomplished analyst, Mr. A. Wynter Blyth. The results will be published in detail in due course; but it may here be stated that they were in the main eminently satisfactory. The vital capacity was not, perhaps, quite so great as we were prepared for, and the grip—a matter of little moment, however, in such an undertaking—was what might have been expected from the pedestrian's comparatively slight physique. But the clinical thermometer and the sphygmograph proclaimed that the temperature and the pulse—both unerring indicators of abnormal states of health—were perfectly natural; indeed, the tracings with the former—one of Dudgeon's beautiful little instruments—were typical of the most perfect health. Weston's average rate of walking was over four miles an hour; but he usually raised the figure to six when finishing his final mile for the day. His 4,999th mile was completed in gallant style, amidst the vociferous cheers of the crowd of sympathising spectators, in 9 minutes and 17 seconds, or at the rate of about 6·70 miles an hour. When the pedestrian set out on his tour from the Palace Chambers, Bridge Street, Westminster, on the 21st November last, at midnight, he was suffering from a severe cold, and was strongly advised to wait till he was well; but he determined to make the start on the day that had been fixed, feeling confident that if he could tide over the first week and month all would be well, a confidence which has been abundantly justified, for, as a matter of fact, Weston improved in health and condition as he drew towards the conclusion of his tour; and, so thoroughly *well* did he evidently feel on its completion, that he stated his readiness to walk on the following Monday to Brighton and back—a distance of 106 miles—without a rest, if some generous philanthropist would give £100 to the Police Orphanage, he himself contributing another £50.

The feat, as we have said, is a great victory for the apostles of total abstinence from alcohol, although it would be absurd to contend that because Weston accomplished this extraordinary feat, anyone could do it. As Dr. Richardson and Dr. Norman Kerr truly remarked in their speeches on Saturday, a man may daily take so small an amount in, say, some light beer, as to practically be of no effect one way or the other; but when he resorts to it as a promoter of strength or sustained physical effort, and takes a quantity such as he believes is necessary for that purpose, it is *then* that he will discover his error. Herein lies the value of the present enterprising undertaking.

The festival dinner of the British Home for Incurables took place at the Freemasons' Tavern yesterday (Tuesday), under the presidency of the Lord Mayor, who was supported by the sheriffs of London and Middlesex.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 19, 1884.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

On Monday next, March 24th, the general body of Fellows and Members of the Royal College of Surgeons of England will be enabled, for the first time, to exercise privileges which have hitherto been withheld from them, and to give expression to their views and opinions respecting the organisation and management of the corporation to which they are attached. So large a concession of right is in itself a benefit of great importance; and the occasion will, if used aright, be made a precedent for future annual gatherings of a similar description. On the question whether such an arrangement is just in principle, it is impossible to express a doubt; nor is it at present easy to forecast the immense advantages that must accrue, from a participation in matters directly concerning themselves, to younger associates of the College, the interests of whom have, in the past, scarcely received that amount of consideration fairly to be claimed for them. A new era in the history of the College is about to be inaugurated; and on the attitude of those who will take part in the preliminary proceedings depends in a large measure the influence to be exerted by impending changes.

In anticipation of the approaching gathering, the Council of the College have drawn up proposals for such alterations in its constitution as seem to them to be called for in response to the recent agitation. These include amendments of the various charters of the Corporation, by which alterations will be effected as follows:

—1. That the amount of property in lands or rents to

be held by the College be increased from £2,000 to £10,000. 2. That the conditions of admission to, and the arrangements for, the Fellowship examination be henceforth determined by resolution of the Council, instead of, as at present, by bye-laws. 3. That the amount of fee payable on account of such examination be omitted from the section of Charter 7th Vic., and that it be settled by bye-law. 4. That the mode of election to the Council be altered to enable voting by papers as well as in person, and that the quorum of Fellows necessary to be present at such election be fixed by bye-law in place of by Charter. 5. That the payment of fees on election as Fellows by Members of twenty years' standing be dispensed with. 6. That the licence in midwifery of the College be entirely abandoned. 7. That the number of examiners in dental surgery be increased, at the desire of the Council, beyond the six now provided for; and that the members of the Board skilled in dental surgery be elected from persons duly registered under the Dentists' Act of 1878.

With the general character of these six proposed alterations of Charter we may at once admit agreement, except in that set forth in No. 5. It should be remembered that Fellows elected under the section it deals with are in reality honorary Fellows of the College, and that the distinction thus conferred on them is in the nature of a complimentary degree, in the same way as an honorary degree conferred by a University. It is true, however, that in the latter case recipients of the honour are not necessarily already members of the University; whereas the honorary Fellowship of the College is given only to *members* who have been so for at least twenty years. But the circumstances under which both presentations are made are in many respects similar, and, as at Oxford graduation fees are exacted from such distinguished persons as obtain the D.C.L. *honoris causa*, so might it be fairly argued that recipients of the F.R.C.S. Eng., *sine examinatione*, should contribute to the funds of the Corporation. It would still remain with the College to grant its Fellowship diploma to specially-distinguished surgeons whose services to science demand unusual recognition, and who may or may not be already enrolled among its members; and in such cases the non-exaction of any fee would add to the graceful nature of the compliment. It might even be considered worth while proposing that such powers should be sought for when Parliamentary sanction is solicited to the alterations already shadowed forth; and if this suggestion be adopted for that described under the fifth heading above, it would be more in keeping with the dignity and advantage of the College.

As we have said, these six proposals for amendment have emanated from the Council, but it is quite certain that they by no means include all that will be named at the meeting on Monday. The "Association of Fellows," it may be taken for granted, will go prepared to advocate much more trenchant reforms than any contained in the official outline; and that they will deal, also, with matters more nearly affecting the interests of official life itself. One very important question not introduced in the Council's circular will surely demand attention, and that is the division of fees payable by

candidates for examination. The Council has so long ruled as an autocratic government that it will be hard for it to appreciate at once the nature of the discussion its proceedings have aroused; and it will be compelled in all probability to listen to suggestions for drastic measures that it will contemplate with some dismay. The appointment of examiners, for instance, is a subject on which outside feeling has long been greatly exercised; and much concern has been created by what have the appearance of radical abuses in this connection. It is scarcely possible to believe that merit alone has at all times dictated the choice that has been made; or that successive re-elections to the same post have followed in natural sequence to an anxious canvas for fit and proper holders thereof. With all deference to the integrity and conscientiousness of the Council as a whole, we cannot disguise the fact that its duty in respect to official appointments is that of nomination alone. To the absence of any kind of consultation with their constituents is it alone due that the members of the Council have so long been able to exercise the powers of patronage they enjoy, added, it may be, to the apathy of Fellows and Members in permitting their own privileges to be dispensed by their representatives. In future it should be the function of the Council to appear before a general yearly meeting of the College, Fellows, and Members, and to submit to it a list of office-bearers, examiners, and others, previously drawn up in Council. Confirmation or alteration of this list ought then to be in the hands of the meeting; and in this way alone can the reproach of one-sidedness or of partial selections be avoided in a matter which is of the first importance, not only to the College, but to the whole profession.

Casual visitors as well as regular frequenters of the College are able to suggest many details in which great advantage would result from the introduction of a spirit of sympathy with the needs of those who use it as a means of study. The demeanour of subordinate officials and attendants affords constant irritation to those who are not accustomed to see servants assume the attitude of masters unrebuked; and it is quite possible that the offensive want of consideration shown by these minor officers towards those whom they do not recognise as having immediate authority over them, would undergo a wholesome change for the better if they held their posts subject to the approval of the College as a body. It may be said that these are small matters in themselves, but as they materially affect the comfort of those who make use of the educational facilities afforded by the museum and library, they possess an importance too great to be entirely overlooked.

The management of the library, again, is pursued upon a plan which causes the utmost inconvenience to large numbers of readers with whom time is a matter of some moment. Notwithstanding it is well known that many persons go to the expense of lodging in town with the set object of reading in this place, the room is closed at all sorts of times, almost without notice, and at the apparent caprice of one or other of the persons whose duty it is to be in charge. Any excuse seems,

in their eyes, to warrant its clearance; and this state of things we emphatically assert is a grievous injury to everyone who has a wish and a right to use the books it contains. The days on which it shall be closed should be irrevocably fixed by bye-law, passed by a general meeting; and we hope this will be insisted on next Monday.

The result of the meeting will be decisive on the part to be taken in the future management of the College by the body of its Fellows and members; and as long as this is borne well in mind there can be little doubt what the nature of it will be.

THE CONTAGIOUSNESS OF TUBERCULOSIS.

A SHORT time since we laid before our readers the opinion of Virchow on the non-infectiousness of tubercle. In the speech reported by us the distinguished pathologist opposed the idea of infection in the ordinary acceptation of the term, and showed that the virus of tubercle was not in any way similar to that of splenic fever, for instance, the poison in this case being of a chemical nature, whilst in tuberculosis it was the bacillus itself that produced the disease, and that the action of the bacillus was simply mechanical—it acted where it was and nowhere else; and that the mode of its transference from one person to another was exactly similar to that in which the itch was transferred, i.e., by contact. If this view prove correct, it will be a great gain to know how and through what channels the bacillus tuberculosis is likely to find its way into the system; and conversely it will be interesting and reassuring to learn how it is not likely to find an entrance. We do not go so far as to say that our knowledge on these points is complete, and that we are in a position to say definitely and distinctly in what way tuberculosis is produced in the human subject. Light, however, has been thrown upon them by means of experiment; and we now propose to give our readers a short account of some of the results that have been reached.

First, as regards the skin. In the vaccination of infants, there is a strong, widespread, and we think wholesome, prejudice against the employment of lymph from the children of tuberculous parents, and from children generally belonging to families known to have been the subjects of tuberculous disease. With a view of deciding the question whether it be possible to inoculate tubercle through the skin, Professor Bollinger, of Munich, last year instituted a series of experiments in the Munich Pathological Institute. These experiments proved to the satisfaction of Dr. Bollinger that the poison of tubercle could not be introduced into the human body by means of vaccination. This conclusion receives support in another direction through the investigations of Herr Luther Meyer, who carefully sought for tubercle bacilli in the vaccination pustules of seven phthisical individuals and failed to find them, or, to put it more strongly, he demonstrated their absence. These results should not make vaccinators less careful in their selection of arms for lymph, but they

may serve to reassure timid parents that the dangers of inoculating the fatal disease along with the prophylactic are but slight.

Looking at the possible introduction of active bacilli through another channel, Drs. Celli and Guarnieri have recently made observations in the Pathological Institute in Rome. It should be noted that the experiments were conducted under the conditions that modern science has shown to be necessary. The results obtained led to the following conclusions: (1) Fresh or preserved sputa, still moist, when they evaporate and are exposed to a strong current of air, are not capable of imparting their contained tubercle bacilli to the surrounding atmosphere. Bearing in mind, however, the tenacity of life that characterises these organisms, they recommend that the spitting cups and other vessels that are used for the reception of sputa be disinfected every day. (2) The expired air of phthisical patients contains no tubercle bacilli or tubercular virus. This does not preclude the possibility of contagion from particles of sputum containing bacilli, nor the possibility of contagion through contact with any other secretion containing tubercle virus. (3) The stagnant air of sick rooms in which phthisical patients have passed the night, even when the windows and doors have been closed and there has been no ventilation, contains no tubercle bacilli or tubercular virus. Further experiments will be made with a view of ascertaining how far direct and pulverised sputa are capable of propagating the disease.

The possibility of contagion entering the system through still another channel, viz., the intestinal tract, has been investigated by Professor Baumgarten, of Königsberg. Not being satisfied with previous experiments in this direction, as there seemed to him to be a possibility that the intestinal tracts of the animals experimented on (rabbits) were not absolutely free from abrasions, he caused the animals in his experiments to be fed, before making his own experiments, with liquid food exclusively. He then gave them fresh milk to which had been added tubercle bacilli; and in another series, bacilli similarly suspended, but not given until decomposition had taken place. In the latter case, even when large quantities of the mixture were given repeatedly, either no result at all followed or only a slight tubercle eruption limited to the *processus vermiformis* and the mesenteric glands. In the first series, however, that in which active bacilli were administered in fresh milk, the results were very different. The animals in this series received, once only, a small quantity of milk in which the bacilli were suspended, and in almost every instance, after the lapse of from ten to twelve weeks, tuberculosis of the intestinal mucous membrane, the mesenteric glands, and the liver, came on; in addition to these organs the lymph glands of the neck and of the lower jaw became affected, numerous tubercle bacilli being present in every case in the tuberculous nodules of the neck. It must be assumed, therefore, that the uninjured mucous membrane of the mouth and pharynx is capable of absorbing bacilli contained in food, and that apparently the tonsils are especially active as absorbing organs, as in some of the

cases tuberculous ulcers containing bacilli were met with on the tonsils.

Professor Baumgarten attributes the diminished contagiousness of the bacilli, as shown in the second series of experiments, to loss or diminution of pathological activity, which, by the by, is not a very complete explanation, but we suppose the best he can give at present. It is worthy of note, however, that the bacilli suspended in the decomposing liquid, do not differ in numbers, shape, nor reaction from those of the first series of experiments. The question of the relationship of the disease in cattle known as "grapes" to tubercle, and the fitness or unfitness of the milk of animals affected with the disease for consumption by human being is one of great interest, to which we hope to revert at some future time.

Notes on Current Topics.

The Double Diploma of Edinburgh.

OUR readers will note from an advertisement in our columns to-day that the Edinburgh College of Physicians has decreed that from October next it will give its licence only in conjunction with a surgical licence, thus ceasing to grant the qualification as a separate medical title to practise. We were aware that this important movement was in contemplation, and so far as it goes, it is in the direction of a complete Scotch qualification. But it must also be noted that the terms upon which the College surrenders its right to grant separate licences are widely different from those upon which it was proposed that the Irish Colleges should make a similar surrender. In Scotland the College of Physicians is still open to the holder of any surgical licence in existence, and it will therefore alienate no claimants for the L.R.C.P. Edin., save the very few, if there be any such, who take a physician's licence at first hand and proceed to practise thereon. The Irish College of Surgeons, on the contrary, was asked to refuse all claimants who were not provided with a passport viséd by the College of Physicians, and thus it would have deprived itself not only of those who take the L.R.C.S.I. as a first and separate qualification, but of those whose medical licence was not approved by the Irish College of Physicians. In fact, the principle of the Scotch double diploma is comprehensible and practical; that of the Irish scheme was unbusinesslike, and as regards the College of Surgeons, suicidal. We are glad to say that, for the present, the latter is in *nubibus*.

It will be readily understood these private arrangements between Colleges are the indications of helplessness and hopelessness respecting the great reform proposed by the Medical Bill. These changes were not thought of, and probably would not have been listened to, if suggested, as long as old corrupt licensing systems were safe from legislative interference, and it may be expected that, if anything should prevent the passing of a Reform Bill, we should hear very little of the greed for examinational improvement which is now the fashion.

This new-born energy is a compliment to the reform party, and a good omen as regards the passing of the Bill, and, so far, we congratulate the profession and the public upon the evidences of an awakening, however late in the day that awakening may have taken place.

The Medical Services in the Soudan.

WE understand that, in recognition of the efficient manner in which the medical service has been carried out in the operations of the Soudan Expeditionary Force, Brigade-Surgeon E. M'Dowell, A.M.D., will be specially promoted to the rank of Deputy Surgeon-General—a rank which at present he temporarily holds while acting as Principal Medical Officer of Major General Graham's force. Occasion will also be taken of conferring upon Surgeon-General J. Irvine, Principal Medical Officer of the British Army of Occupation, the Companionship of the Order of the Bath, for the energy displayed in organising the medical detachments which proceeded from Cairo to Suakim.

The Public Executioner.

THE infliction of a death penalty in a civilised community must always be associated with more or less that is eminently disagreeable to the feelings of those even who do not demand the abolition of this last dread resource of the law. It is, however, a matter for serious concern that an office so responsible as that filled by the common hangman, should ever be held by any save persons fully qualified to perform the functions pertaining to it; and such qualities include a good deal more than simple ability to despatch a fellow-creature in the most expeditious fashion. That every officer elected to the post is not in all respects fitted to occupy it there can be no manner of question; and it would seem that the present acting executioner falls a good deal short of the expectations justified of so important a functionary; so much so, indeed, that a body of jurymen recently condemned him, in very unmistakable terms, of bungling over his work at an execution which took place in Liverpool. It must be remembered, also, that the *dictum* on questions of this kind is a purely medical one, and that an expression of opinion as to the merit of a particular method of hanging on the part of coroners' juries is founded on the report of the surgeon present at the execution. With all the evidence accumulated since the last appointment of hangman, and bearing on his capacity and proceedings, it seems to be clearly indicated that some amendment of the mode of election at least is required; and in this connection it is well to consider whether the interests both of humanity and of seamliness would not best be conserved by merging the choice of public executioners as part of the routine work of Government. Were this done there is little doubt but that skilled assistance would be sought in carrying out the unpleasant task; and the grand result would be that society would be spared the recurrence of those miserable exhibitions which in recent times have so shocked its better-minded members.

London Water.

DR. PERCY F. FRANKLAND presented a very unflattering picture of the water supply of the metropolis in a paper read by him on "The Upper Thames as a Source of Water Supply," at the Society of Arts, on Thursday evening. Notwithstanding all the improvements made along the river banks, Dr. Frankland maintains that the supply is very unsatisfactory, inasmuch as large quantities of deleterious material are still discharged into the river, in spite of all precautions to the contrary. That water so polluted by sewage and other refuse can be at times a grave source of public danger is quite certain; and it is instructive to be reminded by Dr. Frankland that in nearly all other towns in the Thames basin the Thames and its tributaries are rejected as sources of water supply, these towns being generally supplied with spring or deep well water, which is especially abundant in the valley of the Thames. The great obstacle to any improvement such as is here implied, however, is exactly that which the writer of the paper described—viz., the vast capital sunk in existing water works. So great is the influence permitted to be exercised by the interests of this capital that at present it is hopeless to look for any indication of a spirit of sacrifice among holders of water companies' scrip; and as a striking commentary on this may be taken the fact that on the day succeeding the rejection of the Metropolitan Water Bill by the House of Commons shares advanced in value ten and fifteen pounds per cent.

The Insanity of Members of the Animal Protection Society.

M. MAGNAN announced to the Société de Biologie the fact that he had made a discovery which perhaps, he thinks, ought to immortalise his name. His learned colleagues were, no doubt, well pleased to be able to record something new, and listened patiently for half-an-hour to their honourable member, who, in a lengthy communication, developed his ideas on what he called "The Insanity of Members of the Animal Protection Society." He furnished three examples, the most striking of which was that of a lady whose madness consisted in showing an excessive kindness towards the very animals from whom we derive the most benefit—the horse and the dog. Amongst the acts *bizarres* (*sic*) that the lady was guilty of might be mentioned the picking up of broken glass bottles in the street, so that the horses' feet should not be wounded; refusing to hire a horse that was in the act of feeding on the stand, &c. The Société showed its just appreciation by keeping a mute silence until he had finished, and then proceeded to business more worthy of their attention. M. Magnan made one remark, however, that would be very gratifying to all those whose minds are a little more refined than his own, and that was that the kind of "insanity" in question was hereditary in this lady, and it is to be hoped that it will descend to her posterity if she have any. It would be well if the "malady" became contagious so that all France were affected, and then so much brutality would not be witnessed in the streets.

The Lord Mayor and the London Hospital.

ON Wednesday last the Lord Mayor and the Lady Mayoress entertained at dinner, at the Mansion House, the whole of the honorary officers and governing staff of the London Hospital, including the members of the house committee. This graceful compliment to a great charity had its origin in the association of the Lord Mayor with its government, he being an old member of the house committee; and it is also one in which the whole medical profession, of which many representatives were present as guests, participates. The President of the hospital, H.R.H. the Duke of Cambridge, replying to the toast of his health, took occasion to refer to the financial distress into which the institution he presides over is just now plunged; and referring to the fact that less than one-third of its necessary income is derived from endowments, he very strongly urged the claims it possesses to the generosity of the benevolent. Numerous other speeches were made, among others, by Sir Andrew Clark, Senior Physician to the Hospital, who very eloquently defended the medical profession against the unjust and unmerited slights suffered by it at the hands of the general public. The number of ladies and gentlemen present at the dinner exceeded 150.

Charity Organisation.

FOR some time past statements have been current in newspapers and elsewhere tending to show the great hardships to which applicants for relief at the hands of the Charity Organisation Society have to submit. In many instances respectable persons in reduced circumstances, and standing in urgent need of immediate assistance, are reported to have been kept in cruel suspense. The whole of the officers of the Society have carried out a system of very objectionable inquisition into every detail, past, present, and to come, of the applicant's life. Often, too, rather than call day after day only to be again disappointed, candidates have given up all hope of obtaining aid from the Society's agents; and to such a pitch has the feeling of discontent with these proceedings attained among charitable persons, that strenuous efforts are now being made to oppose organised resistance to the system of petty tyranny so long enforced. The first practical result of this movement has been a largely-attended public meeting held at Bethnal Green, under the auspices of the "Charity Protection League," which consists of persons having for an object the counteraction of what is regarded as the disastrous effect of the Charity Organisation Society on the condition of the poor, and on charity in general. At this meeting, which was intended to inaugurate a series of demonstrations, it was resolved to memorialise the Queen to withdraw her name as patron from the Charity Organisation Society. Letters were read from local clergymen, Nonconformist ministers, magistrates, guardians, and others, regretting their inability to be present, and expressing strong sympathy with the movement, the importance of which, both to the Society assailed and to the indigent poor, can hardly be over-estimated.

Overcrowding in Aberdeen.

AN inquiry held at Aberdeen on Thursday last, under the Citizens' Dwelling Act, elicited evidence of the fact that overcrowding exists there to an extent unsurpassed in the poorest and most densely-populated quarter of any large town in the country. It was stated by the chairman of the Public Health Committee that in one house as many as 30 persons were found living in a single room; in another the total population sheltered in 49 houses numbered 788, the number of individual families represented being 240. Further, more than 192 families possessed but a single room as their sole dwelling accommodation, and notwithstanding their unfavourable condition, they paid as much for them as is charged for much superior rooms elsewhere. Dr. Beveridge stated that the Town Council had sought for powers to clear the district in which this state of things exists, and to provide suitable accommodation for the inhabitants; a result which, in the interests of the wretched people themselves, it is devoutly to be hoped may ensue.

IN a paper contributed to the *Medical News* by Dr. F. C. Wilson, descriptive of a case of severe burn-wound unhealed for six years, the author speaks in high terms of skin grafts from the internal membrane of hen's eggs. He employed grafts from this source, and also from the human skin, and that of young rabbits, but none took so effectually, or gave so good a result, as the egg. It should be fresh laid and warm.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 28, Bombay 29, Madras 62, Paris 26, Geneva 36, Brussels 26, Amsterdam 25, Rotterdam 23, The Hague 24, Copenhagen 19, Stockholm 23, Christiania 19, St. Petersburg 37, Berlin 21, Hamburg 27, Dresden 29, Breslau 31, Munich 28, Vienna 30, Prague 35, Trieste 40, Rome 36, Turin 43, Venice 30, Lisbon 40, Brooklyn 17, Philadelphia 21, and Baltimore 21.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 22.5 per 1,000 of their aggregate population. The death-rates in the several towns were:—Birkenhead 13; Derby 16; Brighton, Bristol 17; Wolverhampton 18; Cardiff, Birmingham 19; Edinburgh, Bradford, Portsmouth, Hull, Newcastle-on-Tyne 20; London, Leeds, Norwich 21; Leicester 22; Huddersfield, Sheffield 24; Salford, Liverpool 25; Dublin, Nottingham, Halifax, Blackburn 26; Glasgow 27; Sunderland, Bolton 28; Manchester, Plymouth 29; Oldham 31; Preston 35.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week were—From whooping-cough, 2.4 in Bolton and 1.8 in Huddersfield; from scarlet fever, 2.2 in Leeds, 2.1 in Newcastle-upon-Tyne, and 1.9 in Sheffield; from measles, 3.0 in Nottingham, 2.6 in Oldham, and 2.0 both in Manchester and in Portsmouth; and from "fever," 1.3 in Sunderland. The 32 deaths from diphtheria included 12 in London, 3 each in Edinburgh, Glasgow, and Leeds, 2 in Birmingham, and

2 in Manchester. Small-pox caused 7 deaths in Sunderland, 4 in Birmingham, 2 in Liverpool, 1 in London, and 1 in Wolverhampton.

The Force of Habit in the Insane.

THERE are two very potent factors at work, but exercised in opposite directions, among modern reformers. The *soi-disant* educational reformer in the School Board, for instance, is for cramming the children of the poor with technicalities at the expense of the ratepayer's pocket and the pupil's brain, whilst the workhouse and asylum reformer cuts off such superfluities as beer and tobacco, ostensibly for the saving of the ratepayer's pocket, but at the pauper's loss. A case of the latter kind came before the Metropolitan Asylums Board on Saturday last, on the threat of the auditor to surcharge the Steward of the Leavesden Asylum for the whole year, amounting to about £200, for the allowance of tobacco and snuff to the inmates. Fortunately for the poor lunatics and for the Steward, the opinion of Dr. Case, the medical superintendent, was held to be of greater value than that of Mr. Auditor Roberts, and the Board decided that, as Dr. Case considered the administration of snuff and tobacco to those who had been in the habit of taking them an absolute necessity to imbecile or insane persons, they would call upon the Local Government Board to sanction as legal that which came under the definition of "extras," as ordered by the medical superintendent of the Asylum.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE SCOTCH CORPORATIONS' CONJOINT SCHEME.—The conjoint scheme of the Scotch Corporations may now be said to be a *fait accompli*, and will be presented to the Medical Council at its next meeting. Taken as a whole the scheme demands attention, and we hope in an early issue to consider it in detail. Should it come into force, the scandal which for some time has been attached to the Scotch Corporations will be removed, and with a Medical Council endowed with larger powers and more directly representing the medical profession, any change as far as Scotland is concerned will be unnecessary. The days of the chronics are numbered, and those who have long looked upon the Scotch Colleges as an easy road to the Medical Register will find this hope at last cut off. Some matters of detail may require modification, but the principle of the scheme is sound.

THE EDINBURGH UNIVERSITY TRICENTENARY.—Great preparations are being made in Edinburgh for the celebration of this event, and on the 14th inst. the authorities issued their arrangements in a printed form. A large number of distinguished University authorities are to be present from the Continent and America, honorary degrees are to be freely conferred, there is to be great feasting and illuminations. Notwithstanding his heterodoxy, which our contemporary the *Lancet* so piously and "properly" deplores, the University of Edinburgh has the temerity to confer its degree of LL.D. on the arch-heretic Dr. Maudsley! In view of the large influx of illustrious visitors to our modern Athens, every available bed has been secured at the various hotels in advance, and accommodation is likely to

be both difficult and exceedingly expensive. The profession in Edinburgh has come forward nobly with the private accommodation at its disposal, but this is of necessity limited, and can do no more than assist in the general effort to do honour to the celebration. We hope to give a full account thereof in our next.

GLASGOW HOSPITAL AND DISPENSARY FOR DISEASES OF THE EAR.—At a meeting of the directors of this institution held on the 12th inst., Dr. Barr was elected Aural Surgeon in lieu of Dr. Cassella, resigned in consequence of ill-health. It is the rule to applaud all appointments after they are made: we would not be guilty of any such affectation, and we therefore express our regret at Dr. Barr's appointment, not from any personal objection to himself, but from the fact that out of six possible aural appointments in Glasgow he now holds four. This is, however, quite characteristic of the profession in Glasgow, from Gilmore Hill downwards, and some of our University professors hold pluralities of appointments not at all consistent with their high professional and social pretensions. We would advise Drs. Erskine and Downie to start an institution for themselves, do a fortnight's pilgrimage to Berlin and Vienna, and give an occasional consultation to one or two professors to ensure the respectability and recognition of their institution. There are certain other qualifications required, for which we recommend a perusal of "John Bull and his Island."
